

COVID-19 Weekly Epidemiological Update

Edition 103 published 3 August 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Monthly Operational Update](#)

Global overview

Data as of 31 July 2022

Globally, the number of weekly cases decreased by 9% during the week of 25 to 31 July 2022 as compared to the previous week, with over 6.5 million new cases reported (Figure 1, Table-1). The number of new weekly deaths remained stable this week as compared to the previous week, with over 14 000 fatalities reported. As of 31 July 2022, over 574 million confirmed cases and over 6.3 million deaths have been reported globally.

At the regional level, the number of reported new weekly cases increased in the Western Pacific Region (+20%) and the African Region (+5%); at the same time, it decreased or remained stable in the European Region (-35%), the Eastern Mediterranean Region (-12%), the South-East Asia Region (-2%) and the Region of the Americas (-2%). The number of new weekly deaths increased in the Western Pacific Region (+44%), the Eastern Mediterranean Region (+26%), the South-East Asia Region (+20%), and the African Region (+12%), while it decreased in the European Region (-26%). The number of new weekly deaths in the Region of the Americas was similar to the figure reported during the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 31 July 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest numbers of new weekly cases were reported from Japan (1 379 099 new cases; 42%), the United States of America (923 366 new cases; +2%), the Republic of Korea (564 437 new cases; +25%), Germany (459 724 new cases; -26%), and Italy (394 583 new cases; -26%). The highest numbers of new weekly deaths were reported from the United States of America (2 626 new deaths; -10%), Brazil (1 827 new deaths; +31%), Italy (1 205 new deaths; +27%), Japan (655 new deaths; +141%), and Australia (637 new deaths; +24%).

Current trends in reported COVID-19 cases and deaths should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected. Additionally, data from countries are continuously updated by WHO to incorporate changes in reported COVID-19 cases and deaths made by countries retrospectively.

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 31 July 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Western Pacific	2 618 349 (40%)	20%	71 722 656 (12%)	2 342 (17%)	44%	245 657 (4%)
Europe	1 914 599 (29%)	-35%	240 928 373 (42%)	4 315 (30%)	-26%	2 049 551 (32%)
Americas	1 666 963 (25%)	-2%	170 676 377 (30%)	6 196 (44%)	1%	2 789 118 (44%)
South-East Asia	191 983 (3%)	-2%	59 356 443 (10%)	698 (5%)	20%	792 444 (12%)
Eastern Mediterranean	156 532 (2%)	-12%	22 627 851 (4%)	545 (4%)	26%	345 005 (5%)
Africa	17 253 (<1%)	5%	9 213 803 (2%)	83 (1%)	12%	174 044 (3%)
Global	6 565 679 (100%)	-9%	574 526 267 (100%)	14 179 (100%)	-3%	6 395 832 (100%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

Geographic spread and prevalence of VOCs

Globally, from 1 July to 1 August 2022, 204 668 sequences were collected and uploaded to GISAID. Among these, 203 440 sequences were Omicron variant of concern (VOC) and its descendent lineages, accounting for 99% of sequences reported globally in the past 30 days.

A comparison of sequences submitted to GISAID in epidemiological week 29 (17 to 23 July 2022) and week 28 (10 to 16 July 2022) shows that BA.5 and BA.4 Omicron descendent lineages continued to be dominant globally, with a weekly prevalence that increased from 63.8% to 69.6%, and from 10.9% to 11.8%, respectively. Conversely, within the same time period, BA.2.12.1 and BA.2 sequences showed a decline from 4.4% to 1.9% and from 2% to 1.5%, respectively.

Current trends describing the circulation of Omicron descendent lineages should be interpreted with due consideration of the limitations of SARS-CoV-2 surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as changes in sampling strategies and reductions in testing and sequences being conducted and shared from countries around the world.

For more information on the assessment of SARS-CoV-2 variants and the WHO classification refer to Annex 2.

WHO regional overviews:

Epidemiological week 25 - 31 July 2022**

African Region

The Africa Region reported over 17 000 new cases, a 5% increase as compared to the previous week. However, 14 (31%) countries reported an increase in the number of new cases of 20% or greater, with some of the greatest proportional increases seen in Liberia (30 vs one new case; +2900%), Seychelles (160 vs seven new cases; +2186%), and Rwanda (323 vs 49 new cases; +559%). The highest numbers of new cases were reported from Réunion* (5687 new cases; 635 new cases per 100 000 population), South Africa (2422 new cases; 4.1 new cases per 100 000; +2%), and Burundi (1714 new cases; 14.4 new cases per 100 000; +68%).

The number of new weekly deaths in the Region increased by 12% as compared to the previous week, with 83 new deaths reported. The highest numbers of new deaths were reported from South Africa (39 new deaths; <1 new death per 100 000 population; +56%), Réunion* (seven new deaths; <1 new death per 100 000), and Malawi (seven new deaths; <1 new death per 100 000; +17%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.6 million new cases, a similar number as compared to the previous week. Eight of 56 (14%) countries for which data are available reported increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Montserrat (22 vs seven new cases; +214%), Honduras (5105 vs 2657 new cases; +92%), and Saint Lucia (312 vs 190 new cases; +64%). The highest numbers of new cases were reported from the United States of America (923 366 new cases; 279 new cases per 100 000; +2%), Brazil (284 971 new cases; 134.1 new cases per 100 000; +11%), and Peru (78 692 new cases; 238.7 new cases per 100 000; -9%).

The number of new weekly deaths reported in the Region remained similar to the number reported in the previous week, with just under 6200 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2626 new deaths; <1 new death per 100 000; -10%), Brazil (1827 new deaths; <1 new death per 100 000; +31%), and Canada (253 new deaths; <1 new death per 100 000; +22%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported a 12% decrease in cases this week following an increasing trend observed since late May 2022, with over 156 500 new weekly cases. Five (23%) countries reported increases in the number of new cases of 20% or greater, with the highest proportional increases observed in Yemen (28 vs one new case; +2700%), Somalia (45 vs 12 new cases; +275%), and Jordan (4763 vs 2455 new cases; +94%). The highest numbers of new cases were reported from the Islamic Republic of Iran (61 977 new cases; 73.8 new cases per 100 000; +33%), Lebanon (16 609 new cases; 243.3 new cases per 100 000; -19%), and Iraq (15 888 new cases; 39.5 new cases per 100 000; -38%).

The number of new weekly deaths in the Region increased by 26% as compared to the previous week, with over 545 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (287 new deaths; <1 new death per 100 000; +75%), Tunisia (99 new deaths; <1 new death per 100 000; -17%), and Iraq (27 new deaths; <1 new death per 100 000; +42%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 1.9 million new weekly cases, a 35% decrease as compared to the previous week. Fourteen (23%) countries in the Region reported increases in new cases of 20% or greater, with some of the highest proportional increases observed in Kyrgyzstan (981 vs 88 new cases; +1015%), the Republic of Moldova (5793 vs 3360 new cases; +72%), and the Russian Federation (69 464 vs 41 959 new cases; +66%). The highest numbers of new cases were reported from Germany (459 724 new cases; 552.8 new cases per 100 000; -26%), Italy (394 583 new cases; 661.6 new cases per 100 000; -26%), and France (290 392 new cases; 446.5 new cases per 100 000; -46%).

Over 4300 new weekly deaths were reported in the Region, a 26% decrease as compared to the previous week. The highest numbers of new deaths were reported from Italy (1205 new deaths; two new deaths per 100 000; +27%), France (552 new deaths; <1 new death per 100 000; -27%), and Spain (532 new deaths; 1.1 new death per 100 000; -34%).

Updates from the [European Region](#)

South-East Asia Region

In the South-East Asia Region, the number of new cases plateaued this week following an increasing trend in cases since early June 2022, with over 191 000 new cases reported. Three of the 10 countries (30%) for which data are available showed increases in the number of new cases of 20% or greater, with the largest proportional increases observed in Timor-Leste (18 vs eight new cases; +125%), Sri Lanka (839 vs 452 new cases; +86%) and Nepal (2974 vs 2214; +34%). The highest numbers of new cases were reported from India (131 056 new cases; 9.5 new cases per 100 000; -5%), Indonesia (38 756 new cases; 14.2 new cases per 100 000; +16%), and Thailand (14 323 new cases; 20.5 new cases per 100 000; -15%).

The number of new weekly deaths in the Region increased by 20% as compared to the previous week, with nearly 700 new deaths reported. The highest numbers of new deaths were reported from India (324 new deaths; <1 new death per 100 000; similar to the previous week's figures), Thailand (228 new deaths; <1 new death per 100 000; +42%), and Indonesia (91 new deaths; <1 new death per 100 000; +72%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region continues to report an increasing trend in cases for the sixth consecutive week, with over 2.6 million new cases reported, a 20% increase as compared to the previous week. Twelve (35%) countries reported increases in new cases of 20% or greater, with some of the largest proportional increases observed in the Federated States of Micronesia (5109 vs 111 new cases; +4503%), Cook Islands (195 vs 33 new cases; +491%), and Guam (819 vs 448 new cases; +83%). The highest numbers of new cases were reported from Japan (1 379 099 new cases; 1090.4 new cases per 100 000; +42%), the Republic of Korea (564 437 new cases; 1100.9 new cases per 100 000; +25%), and Australia (306 679 new cases; 1202.7 new cases per 100 000; -18%).

The Region reported over 2300 new weekly deaths, a 44% increase as compared to the previous week. The highest numbers of new deaths were reported from Japan (655 new deaths; <1 new death per 100 000; +141%), Australia (637 new deaths; 2.5 new deaths per 100 000; +24%), and China (403 new deaths; <1 new death per 100 000; -12%).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Monthly Operational Update

The [Monthly operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this edition, highlights of country-level actions and WHO support to countries include:

- The Eastern Mediterranean Region reflects on genomic sequencing and its future within integrated surveillance of respiratory viruses
- Global Outbreak Alert and Response Network (GOARN) field epidemiologists support the COVID-19 response in Papua New Guinea
- WHO/Europe leads regional dialogue on the importance of strong infection prevention and control programmes for COVID-19, monkeypox and beyond
- An ancient tradition to the rescue: Mayan midwives or “comadronas” dispels COVID-19 vaccination fears
- Reviewing the COVID-19 response in Sudan amidst other national emergencies
- Emergency Medical Teams (EMTs) provide support to Eswatini during the COVID-19 pandemic
- Malaysia trials digital community to protect mental health during COVID-19
- Looking back at WHO’s rapid and coordinated response to COVID-19 in Bhutan (2020-21)
- WHO Public Health Laboratories knowledge sharing platform: Enhancing laboratory readiness
- The Access to COVID-19 Tools Accelerator (ACT-A) Health Systems and Response Connector: enhancing the equitable access and implementation of COVID-19 tools
- GOARN Steering Committee selects new leadership and agrees on its upcoming four-year strategy
- “Dear Pandemic”: a communication platform empowering woman to navigate the flood of information on COVID-19, presented as part of WHO’s Science Translation initiative
- OpenWHO online course spurs learners to improve infection prevention and control practices
- WHO’s COVID-19 Response Funding in 2022: Delivering science, solutions and solidarity to end the acute phase of the pandemic
- Updated WHO guidance and publications

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Updates of an outbreak of COVID-19 reported in the Democratic People’s Republic of Korea continue through official media since 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

* For some countries, it was not possible to calculate the weekly percentage change in the number of cases and / or deaths due to batch reporting during the last week.

Annex 2. SARS-CoV-2 variants assessment and classification

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

COVID-19 Weekly Epidemiological Update

Edition 102 published 27 July 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 24 July 2022

Globally, the number of weekly cases reported during the week of 18 to 24 July 2022 was similar to the number reported last week, with over 6.6 million new cases (Figure 1). Likewise, the number of new weekly deaths was similar to the number reported during the previous week, with over 12 600 fatalities.

At the regional level, the number of new weekly cases increased in the Western Pacific Region (+52%), the Eastern Mediterranean Region (+45%) and the South-East Asia Region (+13%), while it decreased in the African Region (-44%), the European Region (-24%) and the Region of the Americas (-12%). The number of new weekly deaths increased in the Eastern Mediterranean Region (+88%), the Western Pacific Region (+19%) and the South-East Asia Region (+8%), while it decreased in the African Region (-47%) and the European Region (-6%). The number of new weekly deaths in the Region of the Americas was similar to the figure reported during the previous week.

As of 24 July 2022, over 567 million confirmed cases and over 6.3 million deaths have been reported globally.

Current trends in reported COVID-19 cases and deaths should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected. Additionally, data are continuously updated to incorporate regular changes made by countries retrospectively.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 24 July 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest numbers of new weekly cases were reported from Japan (969 068 new cases; +73%), the United States of America (860 097 new cases; -3%), Germany (565 518 new cases; -16%), Italy (531 327 new cases; -26%), and France (508 620 new cases; -27%). The highest numbers of new weekly deaths were reported from the United States of America (2 637 new deaths; +3%), Brazil (1 396 new deaths; -20%), Italy (952 new deaths; +21%), Spain (810 new deaths; +33%), and France (737 new deaths; +34%).

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

Geographic spread and prevalence of VOCs

Globally, from 21 June to 21 July 2022, 193 561 sequences were collected and uploaded to GISAID. Among these, 175 679 sequences were the Omicron variant of concern (VOC), accounting for 90.1% of sequences reported globally in the past 30 days. During the same period, Delta VOC and recombinants were observed in 49 (<0.1%) sequences. The remaining 18 223 (9.9%) sequences are waiting to be assigned and presumed to be Omicron.

A comparison of sequences submitted to GISAID in epidemiological week 28 (10 to 16 July 2022) and week 27 (3 to 9 July 2022) shows that BA.4 and BA.5 Omicron subvariants continued to be dominant globally with a weekly prevalence that remained stable, with BA.4 accounting for 11.1% in week 27 and 11.2% in week 28, and BA.5 accounting for 52.4% and 52%, respectively. Conversely, during the same period, BA.2 and BA.2.12.1 sequences showed a decline from 3.6% to 2.2% and from 6.4% to 2.7%, respectively.

Current trends describing the circulation of Omicron sublineages should be interpreted with due consideration of the limitations of SARS-CoV-2 surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as changes in sampling strategies and reductions in testing and sequences being conducted and shared from countries around the world.

For more information on the assessment of SARS-CoV-2 variants and the WHO classification refer to Annex 2.

WHO regional overviews:

Epidemiological week 18 - 24 July 2022**

African Region

The Africa Region reported over 10 000 new cases, a 44% decrease as compared to the previous week. However, seven (14%) countries reported an increase in the number of new cases of 20% or greater, with some of the greatest proportional increases seen in the Democratic Republic of the Congo (245 vs 80 new cases; +206%), Burundi (1023 vs 451 new cases; +127%), and Algeria (348 vs 178 new cases; +96%). The highest numbers of new cases were reported from South Africa (2382 new cases; 4.0 new cases per 100 000 population; -4%), Mauritius (1321 new cases; 103.9 new cases per 100 000; -69%), and Burundi (1023 new cases; 8.6 new cases per 100 000; +127%).

The number of new weekly deaths in the Region decreased by 47% as compared to the previous week, with 55 new deaths reported. The highest numbers of new deaths were reported from South Africa (25 new deaths; <1 new death per 100 000 population; -40%), Zimbabwe (six new deaths; <1 new death per 100 000; +200%), and Ethiopia (five new deaths; <1 new death per 100 000; -50%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.6 million new cases, a 12% decrease as compared to the previous week. Twelve of 56 (21%) countries for which data are available reported increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Bolivia (Plurinational State of) (40 986 vs 14 322 new cases; +186%), Venezuela (Bolivarian Republic of) (2579 vs 1595 new cases; +62%), and Cuba (581 vs 365 new cases; +59%). The highest numbers of new cases were reported from the United States of America (860 097 new cases; 259.8 new cases per 100 000; -3%), Brazil (255 610 new cases; 120.3 new cases per 100 000; -39%), and Mexico (119 613 new cases; 92.8 new cases per 100 000; -34%).

The number of new weekly deaths reported in the Region remained similar to the number reported in the previous week, with over 5700 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2637 new deaths; <1 new death per 100 000; +3%), Brazil (1396 new deaths; <1 new death per 100 000; -20%), and Mexico (376 new deaths; <1 new death per 100 000; -13%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region has been reporting an increasing trend in cases since late May 2022, with over 120 000 new weekly cases, a 45% increase as compared to the previous week. Twelve of 18 (55%) countries reported increases in the number of new cases of 20% or greater, with the highest proportional increases observed in Egypt (231 vs 49 new cases; +371%), Afghanistan (1024 vs 231 new cases; +343%), and the Syrian Arab Republic (106 vs 27 new cases; +293%). The highest numbers of new cases were reported from the Islamic Republic of Iran (46 595 new cases; 55.5 new cases per 100 000; +85%), Tunisia (27 340 new cases; 231.3 new cases per 100 000; +31%), and Iraq (25 573 new cases; 63.6 new cases per 100 000; +33%).

The number of new weekly deaths in the Region increased by 88% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (164 new deaths; <1 new death per 100 000; +188%), Tunisia (119 new deaths; 1.0 new death per 100 000; +59%), and Morocco (33 new deaths; <1 new death per 100 000; +22%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 2.4 million new weekly cases, a 24% decrease as compared to the previous week. Twenty (33%) countries in the Region reported increases in new cases of 20% or greater, with some of the highest proportional increases observed in Azerbaijan (1743 vs 703 new cases; +148%), Kazakhstan (15 001 vs 7190 new cases; +109%), and Kosovo¹ (8333 vs 4507; +85%). The highest numbers of new cases were reported from Germany (565 518 new cases; 680.0 new cases per 100 000; -16%), Italy (531 327 new cases; 890.9 new cases per 100 000; -26%), and France (508 620 new cases; 782.0 new cases per 100 000; -27%).

Over 4200 new weekly deaths were reported in the Region, a 6% decrease as compared to the previous week. The highest numbers of new deaths were reported from Italy (952 new deaths; 1.6 new deaths per 100 000; +21%), Spain (810 new deaths; 1.7 new deaths per 100 000; +33%), and France (737 new deaths; 1.1 new deaths per 100 000; +34%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region has been reporting an increasing trend in cases since early June, with over 196 000 new cases reported, a 13% increase as compared to the previous week. Five of 10 countries (50%) for which data are available showed increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Sri Lanka (452 vs 175 new cases; +158%), Nepal (2214 vs 1091 new cases; 103%) and Myanmar (135 vs 80; +69%). The highest numbers of new cases were reported from India (138 156 new cases; 10.0 new cases per 100 000; +8%), Indonesia (33 389 new cases; 12.2 new cases per 100 000; +41%), and Thailand (16 824 new cases; 24.1 new cases per 100 000; +20%).

The number of new weekly deaths in the Region increased by 8% as compared to the previous week, with over 500 new deaths reported. The highest numbers of new deaths were reported from India (324 new deaths; <1 new death per 100 000; +15%), Thailand (161 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Indonesia (53 new deaths; <1 new death per 100 000; -9%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region has been reporting an increasing trend in cases for the fifth consecutive week, with over 2.1 million new cases reported, a 52% increase as compared to the previous week. Twelve (35%) countries reported increases in new cases of 20% or greater, with some of the largest proportional increases observed in Mongolia (7066 vs 1024 new cases; +590%), Lao People's Democratic Republic (256 vs 149 new cases; +72%), and French Polynesia (696 vs 425 new cases; +64%). The highest numbers of new cases were reported from Japan (969 068 new cases; 766.2 new cases per 100 000; +73%), the Republic of Korea (449 856 new cases; 877.4 new cases per 100 000; +80%), and Australia (376 260 new cases; 1475.5 new cases per 100 000; +64%).

The Region reported over 1600 new weekly deaths, a 19% increase as compared to the previous week. The highest numbers of new deaths were reported from Australia (514 new deaths; 2.0 new deaths per 100 000; +75%), China (457 new deaths; <1 new death per 100 000; -21%), and Japan (272 new deaths; <1 new death per 100 000; +66%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May 2022, data for COVID-19 cases and deaths in Northern Ireland are no longer included in the United Kingdom updates.

^[3] Updates of an outbreak of COVID-19 reported in the Democratic People’s Republic of Korea continue through official media since 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Annex 2. SARS-CoV-2 variants assessment and classification

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

COVID-19 Weekly Epidemiological Update

Edition 101 published 20 July 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 17 July 2022

Globally, during the week of 11 to 17 July 2022, the number of weekly cases plateaued, with just under 6.3 million new cases after an increasing trend for the past five weeks (Figure 1). The reported number of new weekly deaths is increasing with 11 000 fatalities reported.

At the regional level, the number of new weekly cases increased in the Western Pacific Region (+37%), the Region of the Americas (+9%) and the South-East Asia Region (+5%), while it decreased in the African Region (-27%) and the European Region (-16%). The number of new weekly cases in the Eastern Mediterranean Region was similar to the figure reported during the previous week. The number of new weekly deaths increased in the South-East Asia Region (+20%), the Eastern Mediterranean Region (+15%) and the Region of the Americas (+7%), while it decreased in the African Region (-39%) and the European Region (-14%). The number of new weekly deaths in the Western Pacific Region was similar to the figure reported during the previous week.

As of 17 July 2022, over 559 million confirmed cases and over 6.3 million deaths have been reported globally.

Current trends in reported COVID-19 cases and deaths should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected. Additionally, data is continuously updated to incorporate regular changes made by countries retrospectively.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 17 July 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest numbers of new weekly cases were reported from the United States of America (866 479 new cases; +18%), France (757 830 new cases; -15%), Italy (718 925 new cases; +9%), Germany (602 930 new cases; -3%), and Japan (559 111 new cases; +107%). The highest numbers of new weekly deaths were reported from the United States of America (2345 new deaths; +5%), Brazil (1 751 new deaths; +7%), Italy (784 new deaths; +37%), Spain (610 new deaths; -1%), and China (576 new deaths; -17%).

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

Geographic spread and prevalence of VOCs

Globally, from 13 June to 13 July 2022, 200 845 SARS-CoV-2 sequences were collected and submitted to GISAID. Among these sequences, the Omicron VOC remains the dominant variant circulating globally, accounting for 95.4% (191 648) of sequences. The remaining 4.4% (8876) sequences are awaiting PANGO lineage designations and 0.2% (321) are Delta and several recombinants.

Among Omicron sequences, as of epidemiological week 27 (4 to 10 July 2022), BA.2 represents 2.61%, while BA.2.12.1 represents 4.51%, BA.4 represents 10.57%, and BA.5 represents 53.59%. Comparing to the proportion of Omicron sequences collected during epidemiological weeks 26 (27 June to 3 July), BA.2 declined from 3.84% to 2.61%, BA.2.12.1 declined from 10.59% to 4.51%, BA.4 declined from 13.21% to 10.57% while BA.5 increased from 51.84% to 53.59%. Based on the data downloaded from GISAID on 18 July 2022, BA.5 has been reported in 100 countries and continues to drive an increase in cases, hospitalisations and ICU admissions.

Several subvariants of Omicron have emerged and some of these are being monitored by WHOⁱ. BA.2.75 is an Omicron subvariant under monitoring, with earliest sequences reported from May 2022. BA.2.75 has nine additional mutations in the spike compared to BA.2. There is no evidence yet of the extent to which these mutations impact on transmissibility and disease severity compared to other circulating lineages. As of 18 July, 250 sequences of BA.2.75 from 15 countries have been reported on GISAID.

Current trends describing the circulation of Omicron subvariants should be interpreted with due consideration of the limitations of SARS-CoV-2 surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as changes in sampling strategies and reductions in testing and sequences being conducted and shared from countries around the world.

For more information on the assessment of SARS-CoV-2 variants and the WHO classification refer to Annex 2.

Table 3. Summary of phenotypic characteristics* of the Omicron VOC

Public health domain of impact	Omicron (B.1.1.529)	Omicron sublineages			
		BA.1	BA.2	BA.4	BA.5
Transmissibility	Growth advantage and increased transmissibility compared to Delta ⁱⁱ	Lower growth advantage compared to BA.2 ¹ , BA.4 and BA.5 ²	Lower growth advantage compared to BA.4 and BA.5 ^{1,2}	Growth advantage compared to BA.2 ²	Growth advantage compared to BA.4 ²
Disease severity	Overall evidence suggests lower severity despite contrasting evidence. Earlier studies reported lower severity compared to Delta. ³⁻⁷ However, more recent studies in different settings reported similar ^{8,9} or increased severity ¹⁰ compared to Delta. ^{3-7,11 12}	No difference in disease severity compared to BA.2, BA.4 and BA.5 ¹³	No difference in disease severity compared to BA.4 and BA.5 ¹³	Currently available evidence does not suggest a difference in disease severity compared to BA.2 and BA.5 ¹³	Currently available evidence does not suggest a difference in disease severity compared to BA.2 and BA.4 ¹³
Risk of reinfection	Reduced risk of Omicron reinfection among individuals previously infected with a different SARS-CoV-2 variant compared to naïve individuals ^{14,15}	Reduced risk of reinfection with BA.1 after infection with BA.2 ¹⁵	Reduced risk of reinfection following infection with BA.1 ¹⁵	Protection against infection following previous BA.2 infection ¹⁶	Protection against infection following previous BA.2 infection ¹⁶
Impact on antibody responses	Reduction in neutralizing activity reported as compared to other VOCs ¹⁷⁻¹⁹	Lower neutralising antibody titers compared to the index virus ¹⁹	Lower neutralising antibody titers compared to the index virus ¹⁹	Lower neutralizing antibody titres (7.6-fold) compared to BA.1 ^{20,21}	Lower neutralising antibody titres (7.5-fold) compared to BA.1 ^{20,21}
Impacts on diagnostics	PCR assays that include multiple gene targets maintain their accuracy to detect Omicron ²² ; S gene target failure/positivity (SGTF) may be a proxy for screening. Limited to no impact on sensitivity of Ag-RDTs observed ²³⁻²⁶	S gene target failure	The majority will be S gene target positive	S gene target failure.	S gene target failure.
Impact on treatment	No difference in the effectiveness of antiviral agents (polymerase and protease inhibitors) against the Omicron variant ²⁷ . Conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduced effectiveness of other monoclonal antibodies ²⁸⁻³¹	Reduced efficacy of cilgavimab ³² and casirivimab-imdevimab ³³	Reduced neutralising activity of sotrovimab, bamlanivimab, casirivimab, etesevimab, imdevimab and tixagevimab ³⁴	Reduced neutralising activity of sotrovimab, bamlanivimab, casirivimab, etesevimab, imdevimab and tixagevimab. Increased resistance to cilgavimab compared to BA.2 ³⁴	Reduced neutralising activity of sotrovimab, bamlanivimab, casirivimab, etesevimab, imdevimab and tixagevimab. Increased resistance to cilgavimab compared to BA.2 ³⁴
Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant				

ⁱⁱ Similar methodology used as Reference ¹

Figure 5. Vaccine effectiveness (VE) of primary series and first booster vaccination against the Omicron variant of concern

Dots represent point estimates of VE from each study; dark black horizontal lines represent median VE across all studies in stratum. All data is from a systematic review of COVID-19 VE studies; [methods](#) and [summary tables](#) of VE studies can be found on [view-hub.org](#). Vertical panels represent VE for full primary series (grey dots) and VE for homologous or heterologous booster vaccination (other colored dots) following completion of primary series vaccination with vaccine of primary series noted in panel header. All booster VE estimates are for first booster dose. Severe disease includes hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots are provided in text.

Figure 5 summarises the impact of the Omicron variant on absolute vaccine effectiveness (VE) over time, grouped by the primary series vaccine; booster doses may have been a different vaccine (i.e., both homologous and heterologous booster vaccination VEs are shown). Additional information on vaccine performance against VOCs can also be found in Annex 3.

Since the last update, one new study (not yet peer reviewed) has been added to the figure. The study assessed the VE of two and three doses of Pfizer BioNTech-Comirnaty against emergency department admissions and hospitalization due to Omicron BA.1 and BA.2 sub-lineages over time among adults 18 years and older in the United States of America.³⁵

For more information on the methods for Figure 5 refer to Annex 4.

Interpretation of the results of absolute VE for the Omicron variant

To date, 34 studies from 14 countries (Argentina, Brazil, Canada, Chile, Czech Republic, Denmark, Finland, Norway, Israel, Qatar, South Africa, the United Kingdom, the United States of America, and Zambia) have collectively assessed the protection of six vaccines against the Omicron variant (12 studies contributed VE estimates of primary series vaccination, four contributed to estimates of first booster vaccination only, and 18 contributed to both). Findings from these studies show reduced VE of COVID-19 primary series vaccines against the Omicron variant for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for the other four VOCs. Importantly though, VE estimates against the Omicron variant remain higher for *severe disease* than the other outcomes, in the majority of studies. The first booster vaccination substantially improves VE for all outcomes and for all combinations of schedules with estimates available for both primary series and booster vaccination. VE declines more with time after the first booster vaccination for symptomatic disease and infection than it does for severe disease³⁶; however, studies that assess VE of booster vaccination beyond six months to evaluate longer duration of protection are not yet available.

For *severe disease*, VE of the primary series showed little decline over six months. VE was $\geq 70\%$ during the first three months after primary series vaccination for seven of 13 (54%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty). Of the two vector vaccines studies available, both had VE $< 70\%$: one reported VE $< 70\%$ for AstraZeneca-Vaxzevria and the other reported VE $< 50\%$ for Janssen-Ad26.COVS.2.S. Four estimates were available for inactivated vaccines: none of the three estimates for Sinovac-CoronaVac were $\geq 70\%$ (two [67%] were $\geq 50\%$); the single estimate for Beijing CNBG-BBIBP-CorV (Sinopharm) was $< 70\%$ but $\geq 50\%$. Beyond three months after vaccination VE was $\geq 70\%$ for 13 of 33 (39%) VE estimates for the mRNA vaccines (23 [70%] had VE $\geq 50\%$); one of 13 (8%) AstraZeneca-Vaxzevria VE estimates was $\geq 70\%$ (9 [69%] were $\geq 50\%$); neither of the two estimates for the other vector-based vaccine, Janssen-Ad26.COVS.2.S, was $\geq 50\%$; the two VE estimates for Sinovac-CoronaVac were $\geq 50\%$ but $< 70\%$.

The first booster dose vaccination improved VE against *severe disease* in all studies, and VE was $\geq 70\%$ in 36 (95%) of 38 estimates evaluating VE between 14 days and three months of receipt of a booster dose (35 estimates evaluated an mRNA booster, two evaluated a Janssen-Ad26.COVS.2.S booster, and one evaluated a Sinovac-CoronaVac booster); one Moderna-Spikevax booster dose had VE $< 50\%$, and one Janssen-Ad26.COVS.2.S booster dose had VE $< 70\%$. At three to six months post mRNA booster, VE was $\geq 70\%$ for 25 of 28 (89%) estimates (the primary series was an mRNA vaccine in 19 of the 28 estimates, AstraZeneca-Vaxzevria in eight and Sinovac-CoronaVac in one). One study found the VE to be $< 70\%$ but $\geq 50\%$ following three to six months from the third dose of Sinovac-CoronaVac.

VE against *symptomatic disease* and *infection* within the first three months of primary series vaccination was lower than against severe disease, and VE decreased more substantially over time. For *symptomatic disease*, only three of 14 (21%) VE estimates for the mRNA vaccines were $\geq 70\%$ and only seven (50%) were $\geq 50\%$; one (25%) of the four VE estimates for AstraZeneca-Vaxzevria was $\geq 70\%$ while the remaining three estimates were $< 50\%$; the single estimate for Janssen-Ad26.COV2.S was $\geq 70\%$, and both estimates for Sinovac (CoronaVac) were $< 50\%$. Beyond three months after vaccination, only one of 35 (3%) VE estimates was $\geq 50\%$ (25 estimates evaluated mRNA vaccines, eight evaluated AstraZeneca-Vaxzevria, and two evaluated Sinovac-CoronaVac). mRNA booster vaccination after completion of a primary series of an mRNA vaccine, AstraZeneca-Vaxzevria, or Sinovac-CoronaVac improved VE against *symptomatic disease*: six of 23 (26%) VE estimates between 14 days and three months post booster were $\geq 70\%$ (18 [78%] were $\geq 50\%$); one (50%) of two VE estimates evaluating three doses of AstraZeneca-Vaxzevria was $\geq 50\%$ but $< 70\%$, as was the single estimate for three doses of Janssen-Ad26.COV2.S, and the single estimate for three doses of Sinovac-CoronaVac was $< 50\%$. However, first booster dose protection declined rapidly over time: only four of 15 (27%) estimates available at three to six months following receipt of an mRNA booster dose had VE $\geq 50\%$ and none were $\geq 70\%$. Neither the single estimate for three doses of AstraZeneca-Vaxzevria nor the single estimate for three doses of Sinovac-CoronaVac assessed three to six months post booster vaccination was above 50%. VE against *infection* showed a similar pattern of waning as that against *symptomatic disease*.

WHO regional overviews:

Epidemiological week 11 - 17 July 2022**

African Region

The African Region reported a decline in the number of new weekly cases, with over 15 000 new cases reported, a 27% decrease as compared to the previous week. Seven (14%) countries reported an increase in the number of new cases of 20% or greater, with the greatest proportional increases seen in Burundi (451 vs 169 new cases; +167%), Senegal (263 vs 133 new cases; +98%), and Eritrea (40 vs 23 new cases; +74%). The highest numbers of new cases were reported from Réunion (3599 new cases; 402 new cases per 100 000 population; +25%), South Africa (2482 new cases; 4.2 new cases per 100 000; +25%), and Zambia (1200 new cases; 6.5 new cases per 100 000; -17%).

The number of new weekly deaths in the Region decreased by 39% as compared to the previous week, with just under 90 new deaths reported. The highest numbers of new deaths were reported from South Africa (42 new deaths; <1 new death per 100 000 population; -34%), Ethiopia (10 new deaths; <1 new death per 100 000; -23%), and Réunion (six new deaths; <1 new death per 100 000; -14%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.7 million new cases, a 9% increase as compared to the previous week. Eighteen of 56 (32%) countries for which data are available reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Sint Eustatius (69 vs 18 new cases; +283%), Peru (67194 vs 32889 new cases; +104%), and Saint Vincent and the Grenadines (114 vs 56 new cases; +104%). The highest numbers of new cases were reported from the United States of America (866 479 new cases; 261.8 new cases per 100 000; +18%), Brazil (419 273 new cases; 197.2 new cases per 100 000; +6%), and Mexico (141 241 new cases; 109.5 new cases per 100 000; -20%).

The number of new weekly deaths reported in the Region increased by 7% as compared to the previous week, with over 5000 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2345 new deaths; <1 new death per 100 000; +5%), Brazil (1751 new deaths; <1 new death per 100 000; +7%), and Mexico (315 new deaths; <1 new death per 100 000; +32%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

After an increasing trend over the past two months, the Eastern Mediterranean Region reported over 120 000 new weekly cases, a figure similar to last week's figure. Six (27%) countries reported increases in the number of new cases of 20% or greater, with some of the highest proportional increases observed in Libya (453 vs 51 new cases; +788%, partly due to batch reporting), the Islamic Republic of Iran (25 126 vs 8761 new cases; +187%), and Jordan (2135 vs 1329 new cases; +61%). The highest numbers of new cases were reported from the Islamic Republic of Iran (25 126 new cases; 29.9 new cases per 100 000; +187%), Tunisia (20 903 new cases; 176.9 new cases per 100 000; +50%), and Iraq (19 217 new cases; 47.8 new cases per 100 000; -34%).

The number of new weekly deaths in the Region increased by 15% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from Tunisia (75 new deaths; <1 new death per 100 000; +32%), the Islamic Republic of Iran (57 new deaths; <1 new death per 100 000; +46%), and Morocco (27 new deaths; <1 new death per 100 000; -23%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 2.7 million new weekly cases, a 16% decrease from the previous week. Twenty (33%) countries in the Region reported increases in new cases of 20% or greater, with the highest proportional increases observed in Kyrgyzstan (485 vs 78 new cases; +522%), Romania (34 582 vs 7726 new cases; +348%), and Kazakhstan (7190 vs 2293 new cases; +214%). The highest numbers of new cases were reported from France (757 830 new cases; 1165.2 new cases per 100 000; -15%), Italy (718 925 new cases; 1205.4 new cases per 100 000; +9%), and Germany (602 930 new cases; 725.0 new cases per 100 000; -3%).

Over 3000 new weekly deaths were reported in the Region, a 14% decrease as compared to the previous week. The highest numbers of new deaths were reported from Italy (784 new deaths; 1.3 new deaths per 100 000; +37%), Spain (610 new deaths; 1.3 new deaths per 100 000; -1%), and France (530 new deaths; <1 new death per 100 000; +30%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region has been reporting an increasing trend in cases since early June, with over 173 000 new cases reported, a 5% increase as compared to the previous week. Three of 10 countries (30%) for which data were available showed increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Nepal (1091 vs 516 new cases; +111%), Sri Lanka (175 vs 106 new cases; +65%) and Indonesia (23 648 vs 17 388; +36%). The highest numbers of new cases were reported from India (127 948 new cases; 9.3 new cases per 100 000; +6%), Indonesia (23 648 new cases; 8.6 new cases per 100 000; +36%), and Thailand (13 986 new cases; 20 new cases per 100 000; -6%).

The number of new weekly deaths in the Region increased by 20% as compared to the previous week, with over 500 new deaths reported. The highest numbers of new deaths were reported from India (281 new deaths; <1 new death per 100 000; +23%), Thailand (161 new deaths; <1 new death per 100 000; +19%), and Indonesia (58 new deaths; <1 new death per 100 000; +38%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 1.4 million new cases, a 37% increase as compared to the previous week. Fourteen (42%) countries reported increases in new cases of 20% or greater, with some of the largest proportional increases observed in the Lao People's Democratic Republic (149 vs 55 new cases; +171%), Japan (559 111 vs 269 760 new cases; +107%), and the Republic of Korea (249 912 vs 122 234 new cases; +104%). The highest numbers of new cases were reported from Japan (559 111 new cases; 442.1 new cases per 100 000; +107%), the Republic of Korea (249 912 new cases; 487.5 new cases per 100 000; +104%), and Australia (229 874 new cases; 901.5 new cases per 100 000; -11%).

The Region reported over 1300 new weekly deaths, similar to the figure reported during the previous week. The highest numbers of new deaths were reported from China (576 new deaths; <1 new death per 100 000; -17%), Australia (293 new deaths; 1.1 new deaths per 100 000; -1%), and Japan (164 new deaths; <1 new death per 100 000; +52%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May 2022, data for COVID-19 cases and deaths in Northern Ireland was no longer included in the United Kingdom updates.

^[3] Updates of an outbreak of COVID-19 reported in the Democratic People’s Republic of Korea continue through official media since 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Annex 2. SARS-CoV-2 variants assessment and classification

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.¹

Annex 3. Summary of Primary Series and First Booster Vaccine Performance against Omicron Variant of Concern (data as of 11 July 2022)

		Omicron Sub-Lineage				
		BA.1	BA.2	BA.2.12.1	BA.3	BA.4/BA.5
Primary Series Vaccination						
WHO Emergency Use Listing (EUL) Qualified Vaccines	AstraZeneca-Vaxzevria/SII-Covishield	HNR ₁₀	HNR ₁	----	----	----

Abbreviations: HNR=high non-response. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” indicates <2-fold reduction in neutralization; “↓” indicates 2 to <5-fold reduction; “↓↓↓” indicates 5 to <10-fold reduction; “↓↓↓” indicates ≥10-fold reduction. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/sub-lineage was used. HNR indicates a median percent response across all studies of <75%; in these instances, fold-reductions can be biased and, thus, are not presented. The number of studies is shown as subscripts.

Additional notes on Annex Table 3

- Studies contributing to the table are identified from an ongoing review of the preprint and published literature on neutralization of SARS-CoV-2 variants by COVID-19 vaccines.
- Studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the table.
- Studies of immunocompromised persons are excluded.
- It is important to note that studies vary in population and other methodological considerations which may in part explain some differences when comparing products between different studies. In addition, the reductions summarised in the table do not incorporate uncertainty intervals around the fold reductions which can vary substantially across studies when reported.

Annex 4. Methods for Figure 5

- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative designs conducted when Omicron was the predominant circulating variant. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org.
- Only studies providing VE estimates of individual vaccines are included in the plot; studies assessing combined VE of more than one vaccine are excluded except for studies of heterologous primary and booster schedules where all participants included in a VE estimate received the same brands of vaccines in the same order.
- Only studies providing VE estimates for discrete time intervals since vaccination or estimates with limited follow-up time (such that the median time point falls clearly in one of the intervals for the plot) are included. Studies that only provide VE estimates over a cumulative period of time covering more than one time interval are excluded because they are difficult to interpret due to the marked waning of VE over time with Omicron.
- Only estimates of absolute vaccine effectiveness (i.e., the comparison group is unvaccinated persons) are included in the plot; estimates of relative vaccine effectiveness (e.g., the comparison group is persons having completed the primary series) are excluded as the interpretation of relative vaccine effectiveness is not comparable with absolute vaccine effectiveness.

COVID-19 Weekly Epidemiological Update

Edition 100 published 13 July 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: WHO global situational alert system](#)
- [WHO regional overviews](#)

Global overview

Data as of 10 July 2022

Globally, the number of weekly cases has increased for the fifth consecutive week, after a declining trend since the last peak in March 2022. During the week of 4 to 10 July 2022, over 5.7 million new cases were reported, a 6% increase as compared to the previous week (Figure 1). The number of new weekly deaths was similar to the figure reported during the previous week, with over 9800 fatalities reported to WHO.

At the regional level, the number of new weekly cases increased in the Western Pacific Region (+28%), the Eastern Mediterranean Region (+25%), the South-East Asia Region (+5%), while it decreased in the African Region (-33%) and remained similar to last week's numbers in the European Region (+4%) and the Region of the Americas (-1%). The number of weekly deaths increased in the Eastern Mediterranean Region (+78%) and the South-East Asia Region (+23%), while it decreased in the African Region (-17%) and the Western Pacific Region (-10%). The Region of the Americas and the European Region both reported similar figures as compared to the previous week.

As of 10 July 2022, just under 553 million confirmed cases and over 6.3 million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 10 July 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from France (771 260 new cases; 6%), the United States of America (722 924 new cases; -6%), Italy (661 984 new cases; 30%), Germany (561 136 new cases; -9%), and Brazil (396 781 new cases; -3%). The highest number of new weekly deaths were reported from the United States of America (1987 new deaths; -19%), Brazil (1639 new deaths; 11%), China (692 new deaths; -8%), Spain (619 new deaths; 98%), and Italy (574 new deaths; 33%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 10 July 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 854 636 (49%)	4%	232 128 863 (42%)	2 946 (30%)	0%	2 031 961 (32%)
Americas	1 562 967 (27%)	-1%	165 258 879 (30%)	4 789 (49%)	-4%	2 769 531 (44%)
Western Pacific	1 057 634 (18%)	28%	65 491 304 (12%)	1 377 (14%)	-10%	240 280 (4%)
South-East Asia	164 547 (3%)	5%	58 792 794 (11%)	447 (5%)	23%	790 625 (12%)
Eastern Mediterranean	121 627 (2%)	25%	22 168 063 (4%)	199 (2%)	78%	343 796 (5%)
Africa	14 831 (<1%)	-33%	9 152 899 (2%)	114 (1%)	-17%	173 746 (3%)
Global	5 776 242 (100%)	6%	552 993 566 (100%)	9 872 (100%)	-2%	6 349 952 (100%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

Geographic spread and prevalence of VOCs

Within the last 30 days (10 June to 10 July 2022), 159 848 sequences were submitted to GISAID. The Omicron VOC remains the dominant variant circulating globally, accounting for 84% of sequences reported in the past 30 days. Approximately 15% of sequences reported to GISAID in the last 30 days have not yet been assigned a PANGO lineage but majority are presumed to be Omicron.

Globally, the Omicron lineages BA.2 and BA.2.12.1 show declining trends, while BA.4 and BA.5 show increasing trends. A comparison of sequences submitted to GISAID in epidemiological week 25 (19 to 25 June 2022) and week 26 (26 June to 7 July) shows a decline in BA.2 sequences from 7% to 4% and a decline in BA.2.12.1 sequences from 13% to 7%. Within the same period, the proportion of reported sequences of BA.4 has risen from 11% to 14% and BA.5 from 42% to 50%. BA.5 sequences have been reported from 89 countries.

These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as changes in sampling and sequencing strategies in multiple countries.

For more information on the assessment of SARS-CoV-2 variants and the WHO classification refer to Annex 2.

Special Focus: WHO global situational alert system: a mixed methods multi-stage framework to identify country-level COVID-19 alerts

Background

The COVID-19 pandemic has been marked by periods of increased transmission, at different times, across the globe. In an effort to better identify and respond to surges, WHO developed a global situational alert system, using a mixed methods framework, to support the identification of countries where immediate actions may help mitigate the impact of a surge in COVID-19 morbidity and mortality. The alert system was developed in early May 2021, following the rapid increase in hospitalizations and deaths in India and Nepal, during which time governments and national and international response organizations faced significant challenges and constraints with regard to mobilizing resources, global supplies and workforce to respond to the situation.

Integrated Analytics

Figure 4. Weekly assessment process stages

A global weekly assessment methodology was developed, comprising three main stages (Figure 4).

Stage one: Epidemiological dynamics assessment

An automated statistical risk assessment algorithm based on the daily incidence of cases and deaths reported over the previous week was used to predict the number of COVID-19 associated deaths (a proxy for disease severity) within the next five weeks per one million population. This stage produced an initial alert level.

Stage two: Context assessment

Additional contextual factors were manually assessed using ‘signals’ for each country based on three indicators: (i) health system pressures; (ii) other concerning epidemiological signals (e.g., concurrent outbreaks, concerns related to testing, changes in circulating variants of concern, etc.); and (iii) factors affecting the response – such as mass gatherings, population movement or instability related to acute events resulting in logistical challenges. ‘Signals’ were obtained from event-based surveillance from various sources, including Epidemic Intelligence from Open Sources (EIOS), internet search engines, WHO Regional Office situation reports, Ministry of Health websites and the internal WHO variant tracking database. This was combined with information on vaccination coverage and on the implementation of public health and social measures. An assessment of the trust in available data was attributed for each indicator, ranging from high (reliable data from a trusted source) to unknown (no information consistently output from a country, with limited or no media access). All indicators, and associated trust levels, were combined to produce a recommendation on whether a country should be maintained at the initial alert level, or whether this alert level should be adjusted upwards or downwards by one level based on identified aggravating or mitigating factors, respectively. Based on this, teams at WHO global and regional levels jointly agreed on a final classification for each country.

Stage three: Response

Based on the final classifications, a weekly operational watchlist of countries considered at moderate to critical alert level was produced and shared between WHO Headquarters and Regional Offices to inform and prompt response actions. The global situation alert system has facilitated the release of more than USD 27 million of internal emergency funding to help expedite response activities in at-risk contexts and has enabled the rapid release of operational and technical assistance, including over 450 000 antigen rapid diagnostic tests; over 6000 oxygen concentrators; support to deploy and establish COVID-19 treatment centers; and the deployment of rapid response teams. One of the inherent challenges in the methodology was the relatively short lead-time of the alerts, which limited the ability to influence operational decisions that require considerable advance planning, such as vaccine distribution. As countries became better prepared for future surges in cases and supply chain constraints eased in 2021, the weekly operational watchlist was increasingly used by response teams to facilitate high-level advocacy and guide the work of technical and operational teams.

Next steps

A retrospective qualitative and quantitative review of the process was undertaken between April and June 2022, to inform the use of this system for COVID-19 and of similar systems for future epidemics. Preliminary results suggest that the mixed methods approach, incorporating multiple data sources and allowing for differences in data quality, may have improved the capacity to rapidly identify deteriorating contexts, particularly when there were gaps or delays in official reporting of cases and deaths. This therefore helped to improve the situational assessments in a timely manner. However, developing a standardised global system remained challenging as data availability varied by country over the course of the pandemic. Moreover, despite the benefits of the qualitative assessment, this added a degree of subjectivity based on differing perceptions of risk.

Based on the decreased level of global operational support required for country responses to COVID-19 (due to preparedness and lessons learned over the past two years), a decision was made to pause the WHO global situational alert system for COVID-19 in May 2022. However, some WHO Regional Offices continue to use the system for their respective regions. Triggers which may prompt the reimplementation of the global system for COVID-19 are currently being drafted. Lessons learned are being documented, and the statistical risk assessment algorithm continues to be active, for potential adaptation to future epidemics or pandemics.

Conclusion

The WHO global situational alert system served as a global framework which enabled identification of countries at risk for surges in COVID-19 morbidity and mortality; and in some cases facilitated timely, evidence-based operational decision-making to mitigate these surges. The multi-stage nature of this alert system proved beneficial during the COVID-19 pandemic and the use of this system to inform evidence-based operational action should be explored for other outbreaks and health emergencies. The use of the WHO situational alert system for a different health emergency would nonetheless require adjustment of the parameters and indicators.

WHO regional overviews:

Epidemiological week 4 - 10 July 2022**

African Region

The African Region reported a decline in the number of new weekly cases, with over 14 000 new cases reported, a 33% decrease as compared to the previous week. Fifteen (31%) countries reported an increase in the number of new cases of 20% or greater, with some of the greatest proportional increases seen in Equatorial Guinea (269 vs 119 new cases; +126%), Mayotte (181 vs 81 new cases; +123%), and Gabon (218 vs 115 new cases; +90%). The countries that reported the highest numbers of new cases were Réunion (2869 new cases; 320.4 new cases per 100 000 population; +91%), South Africa (1978 new cases; 3.3 new cases per 100 000; -30%), and Kenya (1524 new cases; 2.8 new cases per 100 000; -33%).

The number of new weekly deaths in the Region decreased by 17% as compared to the previous week, with over 100 new deaths reported. The highest numbers of new deaths were reported from South Africa (64 new deaths; <1 new death per 100 000 population; -21%), Ethiopia (13 new deaths; <1 new death per 100 000; +63%), and Kenya (eight new deaths; <1 new death per 100 000; +100%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.5 million new cases, a figure similar to that of the previous week. Eighteen of 56 (32%) countries for which data are available reported increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Saint Pierre and Miquelon (78 vs 12 new cases; +550%), Honduras (2130 vs 839 new cases; +154%), and Paraguay (12 988 vs 5309 new cases; +145%). The highest numbers of new cases were reported from the United States of America (722 924 new cases; 218.4 new cases per 100 000; -6%), Brazil (396 781 new cases; 186.7 new cases per 100 000; similar to the previous week's figures), and Mexico (137 426 new cases; 106.6 new cases per 100 000; similar to the previous week's figures).

The number of new weekly deaths reported in the Region was similar to that of the previous week, with over 4700 new deaths reported. The highest numbers of new deaths were reported from the United States of America (1987 new deaths; <1 new death per 100 000; -19%), Brazil (1639 new deaths; <1 new death per 100 000; +11%), and Chile (224 new deaths; 1.2 new deaths per 100 000; +26%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 121 000 new weekly cases, representing a 25% increase as compared to the previous week. Ten (45%) countries reported increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Iran (Islamic Republic of) (8761 vs 2776 new cases; +216%), Tunisia (13 947 vs 5477 new cases; +155%), and the occupied Palestinian territory (2735 vs 1350 new cases; +103%). The highest numbers of new cases were reported from Iraq (29 194 new cases; 72.6 new cases per 100 000; +85%), Morocco (17 262 new cases; 46.8 new cases per 100 000; -18%), and Tunisia (13 947 new cases; 118.0 new cases per 100 000; +155%).

The number of new weekly deaths in the Region increased by 78% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from Tunisia (57 new deaths; <1 new death per 100 000; +171%), the Islamic Republic of Iran (39 new deaths; <1 new death per 100 000; +457% increase), and Morocco (35 new deaths; < new death per 100 000; +94%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The number of new weekly cases reported in the European Region was similar to that of the previous week, with over 2.8 million new cases reported. Twenty-one (34%) countries in the Region reported increases in new cases of 20% or greater, with some of the greatest proportional increases observed in Kazakhstan (2293 vs 959 new cases; +139%), Kosovo^[1] (1886 vs 849 new cases; +122%), and the Republic of Moldova (1014 vs 465 new cases; +118%). The highest numbers of new cases were reported from France (771 260 new cases; 1185.8 new cases per 100 000; +6%), Italy (661 984 new cases; 1109.9 new cases per 100 000; +30%), and Germany (561 136 new cases; 674.7 new cases per 100 000; -9%).

Over 2900 new weekly deaths were reported in the Region, similar to the previous week's figure. The highest numbers of new deaths were reported from Spain (619 new deaths; 1.3 new deaths per 100 000; +98%), Italy (574 new deaths; 1.0 new deaths per 100 000; +33%), and France (382 new deaths; <1 new death per 100 000; +52%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region has been reporting an increasing trend in cases since early June, with over 164 000 new cases reported, a 5% increase as compared to the previous week. Four of 10 countries (40%) for which data were available showed increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Nepal (516 vs 268 new cases; +93%) and Sri Lanka (106 vs 87 new cases; +22%). The highest numbers of new cases were reported from India (120 222 new cases; 8.7 new cases per 100 000; +7%), Indonesia (17 388 new cases; 6.4 new cases per 100 000; +29%), and Thailand (14 938 new cases; 21.4 new cases per 100 000; -6%).

The number of new weekly deaths in the Region increased by 23% as compared to the previous week, with over 400 new deaths reported. The highest numbers of new deaths were reported from India (229 new deaths; <1 new death per 100 000; +15%), Thailand (135 new deaths; <1 new death per 100 000; +25%), and Indonesia (42 new deaths; <1 new death per 100 000; +31%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 1 million new cases, a 28% increase as compared to the previous week. Fifteen (45%) countries reported increases in new cases of 20% or greater, with some of the largest proportional increases observed in Vanuatu (315 vs 100 new cases; +215%), French Polynesia (302 vs 118 new cases; +156%), and the Republic of Korea (122 234 vs 63 592 new cases; +92%). The highest numbers of new cases were reported from Japan (269 760 new cases; 213.3 new cases per 100 000; +98%), Australia (257 002 new cases; 1007.9 new cases per 100 000; +22%), and China (223 915 new cases; 15.2 new cases per 100 000; +17%).

The Region reported over 1300 new weekly deaths, representing a 10% decrease as compared to the previous week. The highest numbers of new deaths were reported from China (692 new deaths; <1 new death per 100 000; -8%), Australia (295 new deaths; 1.2 new deaths per 100 000; -11%), and Japan (108 new deaths; < 1 new death per 100 000; -44%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May 2022, data for COVID-19 cases and deaths in Northern Ireland was no longer included in the United Kingdom updates.

^[3] Updates of an outbreak of COVID-19 reported in the Democratic People’s Republic of Korea continue through official media since 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Annex 2. SARS-CoV-2 variants assessment and classification

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

COVID-19 Weekly Epidemiological Update

Edition 99 published 6 July 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 3 July 2022

Globally, the number of weekly cases has increased for the fourth consecutive week, after a declining trend since the last peak in March 2022. During the week of 27 June to 3 July 2022, over 4.6 million new cases were reported, a figure similar to that of the previous week (Figure 1). The number of new weekly deaths decreased by 12%, with over 8100 fatalities reported.

At the regional level, the number of new weekly cases increased in the Eastern Mediterranean Region (+29%), the South-East Asia Region (+20%), the European Region (+15%), and the Western Pacific Region (+4%), while it decreased in the African Region (-33%) and the Region of the Americas (-18%). The number of new weekly deaths increased in the Eastern Mediterranean Region (+34%) and the South-East Asia Region (+16%), while decreases were observed in the African Region (-50%), the Region of the Americas (-13%), the European Region (-12%) and the Western Pacific Region (-12%).

As of 3 July 2022, over 546 million confirmed cases and over 6.3 million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 3 July 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest numbers of new weekly cases were reported from France (603 074 new cases; +33%), Germany (555 331 new cases; -2%), Italy (511 037 new cases; +50%), the United States of America (496 049 new cases; -29%), and Brazil (334 852 new cases; -4%).

The highest numbers of new weekly deaths were reported from the United States of America (1 622 new deaths; -19%), Brazil (1 187 new deaths; -10%), China (755 new deaths; -30%), Italy (430 new deaths; +21%), and the Russian Federation (371 new deaths; -14%).

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.¹

Geographic spread and prevalence of VOCs

The Omicron VOC continues to be the dominant variant circulating globally, accounting for 92% of sequences reported to GISAID between 1 and 30 June 2022. The remaining 8% waiting to be assigned are (presumed Omicron), Delta VOC and recombinants. Among Omicron lineages, the proportions of BA.5 and BA.4 continue to increase. BA.5 has been detected in 83 countries, and during epidemiological week 25 (19 to 25 June), the proportion of BA.5 among all sequences submitted weekly to GISAID increased from 37% to 52% (Table 2). Although BA.4 is also rising globally, the rate of increase is not as high as that of BA.5. BA.4 has been detected in 73 countries, and now accounts for 12% of all sequences submitted during week 25 (up from 11% in the previous week). BA.4 and BA.5 share similar mutations in SARS-CoV-2 spike but have different mutations in non-spike regions.

Globally, the proportions of Omicron lineages BA.2 and BA.2.12.1 have decreased as compared to week 23 (5 to 11 June). During week 25, the prevalence of BA.2 among all sequences submitted to GISAID was 9% (a decrease from 16% in the previous week) and the prevalence of BA.2.12.1 was 11% (a decrease from 19% in the previous week). BA.2 and BA.2.12.1 have been reported in 150 and 84 countries, respectively. There is no evidence yet regarding any change in severity with BA.4, BA.5 or BA.2.12.1 as compared to BA.2. However, the rise in prevalence of BA.2.12.1, BA.4 and BA.5 has coincided with an increase in cases in several WHO regions. In some countries, the rise in cases also resulted in a surge in hospitalizations, ICU admissions and deaths. In countries where the incidence of BA.4, BA.5 or BA.2.12.1 cases is now declining, the rise in cases, hospitalizations, ICU admissions and deaths have been lower as compared to the previous BA.1 and/or BA.2 waves. The differences observed in epidemiological situations is likely influenced by a number of factors, including surveillance, vaccination coverage and the implementation of PHSM.

Figure 4. Panel A and B: The number and percentage of SARS-CoV-2 sequences, as of 3 July 2022

Figure 4 Panel A shows the number and Panel B the percentage of all circulating variants since 1 April 2022. Omicron sister-lineages and additional Omicron VOC descendent lineages under further monitoring (VOC-VUM) are shown. BA.1.X and BA.2.X include all BA.1 and BA.2 pooled descendent lineages, except those already shown in the figure above. Source: SARS-CoV-2 sequence data and metadata from GISAID, as of 3 July 2022.

Table 2. Relative proportions of SARS-CoV-2 sequences over the last four weeks by specimen collection date

Lineage	Countries	Sequences ^a	Last 4 weeks by collection date (%) ^b			
			2022-22	2022-23	2022-24	2022-25

Characteristics of Omicron

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Table 2 summarizes the phenotypic characteristics of the Omicron VOC and its sub-lineages for which evidence is available since the [last update on 22 June 2022](#). Some of these studies have not been peer-reviewed and the findings must, therefore, be interpreted with due consideration of this limitation.

Table 3. Summary of phenotypic characteristics* of the Omicron VOC

Public health domain of impact	Omicron (B.1.1.529)	Omicron sublineages			
		BA.1	BA.2	BA.4	BA.5
Transmissibility	Growth advantage and increased transmissibility compared to Delta ¹	Lower transmissibility compared to BA.2 ²	Increased transmissibility compared to BA.1 ²	Growth advantage compared to BA.2 ²	Growth advantage over BA.2 ²
Disease severity	Overall evidence suggests lower severity despite some conflicting results. Earlier studies reported lower severity compared to Delta. ^{3–7} However, more recent studies in different settings reported similar ^{8,9} or increased severity ¹⁰ compared to Delta. ^{3–7,11 12}	No difference in disease severity compared to BA.2 ¹³	No difference in disease severity compared to BA.1 ¹³	Currently available evidence does not suggest a difference in disease severity compared to BA.1 ¹⁴	Currently available evidence does not suggest a difference in disease severity compared to BA.1 ^{15,16}
Risk of reinfection	Reduced risk of Omicron reinfection among individuals previously infected with a different SARS-CoV-2 variant compared to naïve individuals ^{17,18}	Reduced risk of reinfection with BA.1 following infection with BA.2 ¹⁹	Reduced risk of reinfection with BA.2 following infection with BA.1 ¹⁹	No specific data available	No specific data available
Impact on antibody responses	Reduction in neutralizing activity as compared to other VOCs ^{20–22}	Lower neutralising antibody titers compared to the index virus ²¹	Lower neutralising antibody titers compared to the index virus ²¹	Lower neutralising antibody titres (7.6-fold) compared to BA.1 ^{23–25}	Lower neutralising antibody titres (7.5-fold) compared to BA.1 ^{23,25}
Impacts on diagnostics	PCR assays that include multiple gene targets maintain their accuracy to detect Omicron ²⁶ ; S gene target failure/positivity (SGTF) may be a proxy for screening. Limited to no impact on sensitivity of Ag-RDTs observed ^{27–30}	S gene target failure.	The majority will be S gene target positive (SGTP).	S gene target failure.	S gene target failure.
Impact on treatment	No difference in the effectiveness of antiviral agents (polymerase and protease inhibitors) against the Omicron variant ³¹ . Conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduced effectiveness of other monoclonal antibodies ^{32–35}	Reduced efficacy of cilgavimab ³⁶ and casirivimab-imdevimab ³⁷	Reduced neutralising activity of sotrovimab ^{36, 37} , casirivimab and imdevimab ³⁸	Reduced neutralising activity of cilgavimab ³⁸ , casirivimab and imdevimab ³⁸	Reduced neutralising activity of cilgavimab ³⁸ , casirivimab and imdevimab ³⁸
Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant.				

¹ Similar methodology used as Reference ¹

Figure 5 summarizes the impact of the Omicron variant on vaccine effectiveness (VE) over time, grouped by the primary series vaccine; booster doses may have been a different vaccine (i.e., both homologous and heterologous booster vaccination VEs are shown). Additional information on vaccine performance against VOCs can also be found in Annex 2.

Methods for Figure 5

- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative designs conducted when Omicron was the predominant circulating variant. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org.
- Only studies providing VE estimates of individual vaccines are included in the plot; studies assessing combined VE of more than one vaccine are excluded except for studies of heterologous primary and booster schedules where all participants included in a VE estimate received the same brands of vaccines in the same order.
- Only studies providing VE estimates for discrete time intervals since vaccination or estimates with limited follow-up time (such that the median time point falls clearly in one of the intervals for the plot) are included. Studies that only provide VE estimates over a cumulative period of time covering more than one time interval are excluded because they are difficult to interpret due to the marked waning of VE over time with Omicron.
- Only estimates of absolute vaccine effectiveness (i.e., the comparison group is unvaccinated persons) are included in the plot; estimates of relative vaccine effectiveness (e.g., the comparison group is persons having completed the primary series) are excluded as the interpretation of relative vaccine effectiveness is not comparable with absolute vaccine effectiveness.

Interpretation of the results of absolute VE for the Omicron variant

To date, 33 studies from 14 countries (Argentina, Brazil, Canada, Chile, Czech Republic, Denmark, Finland, Norway, Israel, Qatar, South Africa, the United Kingdom, the United States of America, and Zambia) have collectively assessed the protection of six vaccines against the Omicron variant (12 studies contributed VE estimates of primary series vaccination only, four contributed to estimates of first booster vaccination only, and 17 contributed to both). Findings from these studies show reduced VE of COVID-19 primary series vaccines against the Omicron variant for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for the other four VOCs. Importantly though, VE estimates against the Omicron variant remain higher for *severe disease* than the other outcomes, in the majority of studies. The first booster vaccination substantially improves VE for all outcomes and for all combinations of schedules with estimates available for both primary series and booster vaccination. VE declines more over time after the first booster vaccination for symptomatic disease and infection than it does for severe disease³⁹; however, studies that assess VE of booster vaccination beyond six months to evaluate longer duration of protection are not yet available.

For *severe disease*, VE of the primary series showed little decline over six months. VE was $\geq 70\%$ during the first three months after primary series vaccination for seven of 13 (54%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty). Of the two vector vaccines studies available, both had VE $< 70\%$: one reported VE $< 70\%$ for AstraZeneca-Vaxzevria and the other reported VE $< 50\%$ for Janssen-Ad26.COV2.S. Four estimates were available for inactivated vaccines: none of the three estimates for Sinovac-CoronaVac were $\geq 70\%$ (2 [67%] were $\geq 50\%$); the single estimate for Beijing CNBG-BBIBP-CorV was $< 70\%$ but $\geq 50\%$. Beyond three months after

vaccination, VE was $\geq 70\%$ for 14 of 29 (48%) VE estimates for the mRNA vaccines (20 [69%] had VE $\geq 50\%$); one of 13 (8%) AstraZeneca-Vaxzevria VE estimates was $\geq 70\%$ (9 [69%] were $\geq 50\%$); neither of the two estimates for the other vector-based vaccine, Janssen-Ad26.COVS.2, was $\geq 50\%$; the two VE estimates for Sinovac-CoronaVac were $\geq 50\%$ but $< 70\%$.

The first booster dose vaccination improved VE against *severe disease* in all studies, and VE was $\geq 70\%$ in 34 (94%) of 36 estimates evaluating VE between 14 days and three months of receipt of a booster dose (33 estimates evaluated an mRNA booster, two evaluated a Janssen-Ad26.COVS.2 booster, and one evaluated a Sinovac-CoronaVac booster); one Moderna-Spikevax booster dose had VE $< 50\%$, and one Janssen-Ad26.COVS.2 booster dose had VE $< 70\%$. At three to six months post mRNA booster, VE was $\geq 70\%$ for 21 of 26 (81%) estimates (the primary series was an mRNA vaccine in 17 of the 26 estimates, AstraZeneca-Vaxzevria in eight and Sinovac-CoronaVac in one). One study found the VE to be $< 70\%$ but $\geq 50\%$ following three to six months from the third dose of Sinovac-CoronaVac.

VE against *symptomatic disease* and *infection* within the first three months of primary series vaccination was lower than against severe disease, and VE decreased more substantially over time. For *symptomatic disease*, only three of 14 (21%) VE estimates for the mRNA vaccines were $\geq 70\%$ and only seven (50%) were $\geq 50\%$; one (25%) of the four VE estimates for AstraZeneca-Vaxzevria was $\geq 70\%$ while the remaining three estimates were $< 50\%$; the single estimate for Janssen-Ad26.COVS.2 was $\geq 70\%$, and both estimates for Sinovac (CoronaVac) were $< 50\%$. Beyond three months after vaccination, there were 31 VE estimates (21 estimates evaluated mRNA vaccines, eight evaluated AstraZeneca-Vaxzevria, and two evaluated Sinovac-CoronaVac), of which only one was $\geq 50\%$. mRNA booster vaccination after completion of a primary series of an mRNA vaccine, AstraZeneca-Vaxzevria, or Sinovac-CoronaVac improved VE against *symptomatic disease*: five of 21 (24%) VE estimates between 14 days and three months post booster were $\geq 70\%$ (16 [76%] were $\geq 50\%$); one (50%) of two VE estimates evaluating three doses of AstraZeneca-Vaxzevria was $\geq 50\%$ but $< 70\%$ as was the single estimate for three doses of Janssen-Ad26.COVS.2, and the single estimate for three doses of Sinovac-CoronaVac was $< 50\%$. However, first booster dose protection declined rapidly over time: only three of 13 (23%) estimates available at three to six months following receipt of an mRNA booster dose had VE $\geq 50\%$ and none were $\geq 70\%$. Neither the single estimate for three doses of AstraZeneca-Vaxzevria nor the single estimate for three doses of Sinovac-CoronaVac assessed three to six months post booster vaccination was above 50%. VE against *infection* showed a similar pattern of waning as that against *symptomatic disease*.

WHO regional overviews:

Epidemiological week 27 June - 3 July 2022**

African Region

The African Region reported a decline in the number of new weekly cases, with over 18 000 new cases reported, a 33% decrease as compared to the previous week. Thirteen (25%) countries reported an increase in the number of new cases of 20% or greater, with some of the greatest proportional increases seen in Mauritania (699 vs 135 new cases; +418%), Equatorial Guinea (92 vs 44 new cases; +109%) and Côte d'Ivoire (638 vs 340 new cases; +88%). The countries that reported the highest numbers of new cases were South Africa (2842 new cases; 4.8 new cases per 100 000 population; -58%), Kenya (2283 new cases; 4.2 new cases per 100 000; -20%), and Ethiopia (2038 new cases; 1.8 new cases per 100 000; -41%).

The number of new weekly deaths in the Region decreased by 50% as compared to the previous week, with over 100 new deaths reported. The highest numbers of new deaths were reported from South Africa (81 new deaths; <1 new death per 100 000 population; -39%), Zimbabwe (nine new deaths; <1 new death per 100 000; -40%), and Ethiopia (eight new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported a decrease in the number of new weekly cases, with over 1.1 million new cases reported, an 18% decrease as compared to the previous week. Fourteen of 46 (30%) countries for which data are available reported increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Saint Kitts and Nevis (155 vs 37 new cases; +319%), Haiti (302 vs 75 new cases; +303%), and Saint Barthélemy (43 vs 26 new cases; +65%). The highest numbers of new cases were reported from the United States of America (496 049 new cases; 149.9 new cases per 100 000; -29%), Brazil (334 852 new cases; 157.5 new cases per 100 000; -4%), and Mexico (97 374 new cases; 75.5 new cases per 100 000; +27%).

The number of new weekly deaths in the Region decreased by 13% as compared to the previous week, with over 3600 new deaths reported. The highest numbers of new deaths were reported from the United States of America (1622 new deaths; <1 new death per 100 000; -19%), Brazil (1187 new deaths; <1 new deaths per 100 000; -10%), and Chile (178 new deaths; <1 new death per 100 000; +12%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported just under 96 000 new weekly cases, representing a 29% increase as compared to the previous week. Eight (36%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in the occupied Palestinian territory (1350 vs 403 new cases; +235%), Iraq (15 791 vs 6237 new cases; +153%), and Tunisia (5477 vs 2277 new cases; +141%). The highest numbers of new cases were reported from Morocco (21 124 new cases; 57.2 new cases per 100 000; +19%), Iraq (15 791 new cases; 39.3 new cases per 100 000; +153%), and the United Arab Emirates (12 347 new cases; 124.8 new cases per 100 000; +11%).

The number of new weekly deaths in the Region increased by 34% as compared to the previous week, with over 100 new deaths reported. Some of the highest numbers of new deaths were reported from Tunisia (21 new deaths; <1 new death per 100 000; +40%), Morocco (18 new deaths; <1 new death per 100 000; +50%), and Saudi Arabia (13 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [Eastern Mediterranean Region](#)

European Region

New weekly cases have continued to increase for over a month in the European Region, with over 2.4 million new cases reported, a 15% increase compared to the previous week. Thirty-one (51%) countries in the Region reported increases in new cases of 20% or greater, with the greatest proportional increases observed in Kosovo^[1] (849 vs 199 new cases; +327%), Kyrgyzstan (29 vs 7 new cases; +314%) and Kazakhstan (959 vs 299 new cases; +221%). The highest numbers of new cases were reported from France (603 074 new cases; 927.2 new cases per 100 000; +33%), Germany (555 331 new cases; 667.7 new cases per 100 000; -2%), and Italy (511 037 new cases; 856.8 new cases per 100 000; +50%).

Over 2300 new weekly deaths were reported in the Region, a 12% decrease as compared to the previous week. The highest numbers of new deaths were reported from Italy (430 new deaths; <1 new death per 100 000; +21%), the Russian Federation (371 new deaths; <1 new death per 100 000; -14%), and Spain (312 new deaths; <1 new death per 100 000; -2%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region has been reporting an increasing trend in cases since early June, with over 157 000 new cases reported, a 20% increase as compared to the previous week. Five of 10 countries (50%) for which data are available showed increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Bhutan (103 vs 48 new cases; +115%), Nepal (268 vs 171 new cases; +57%) and Bangladesh (13516 vs 8846 new cases; +53%). The highest numbers of new cases were reported from India (112 456 new cases; 8.1 new cases per 100 000; +21%), Thailand (15 950 new cases; 22.9 new cases per 100 000; +6%), and Bangladesh (13 516 new cases; 8.2 new cases per 100 000; +53%).

The number of new weekly deaths in the Region increased by 16% as compared to the previous week, with over 350 new deaths reported. The highest numbers of new deaths were reported from India (200 new deaths; <1 new death per 100 000; +39%), Thailand (108 new deaths; <1 new death per 100 000; -14%), and Indonesia (32 new deaths; <1 new death per 100 000; +7%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

After a decreasing trend in cases since mid-May, the Western Pacific Region reported a slight increase in new weekly cases, with over 827 000 new cases, a 4% increase as compared to the previous week. Thirteen (39%) countries reported increases in new cases of 20% or greater, with some of the largest proportional increases observed in the Commonwealth of the Northern Mariana Islands (190 vs 87 new cases; +118%), Palau (36 vs 20 new cases; +80%) and New Caledonia (822 vs 513 new cases; +60%). The highest numbers of new cases were reported from China (270 446 new cases; 18.4 new cases per 100 000; -19%), Australia (210 389 new cases; 825.1 new cases per 100 000; +7%), and Japan (136 357 new cases; 107.8 new cases per 100 000; +25%).

The Region reported over 1500 new weekly deaths, representing a 12% decrease as compared to the previous week. The highest numbers of new deaths were reported from China (755 new deaths; <1 new death per 100 000; -30%), Australia (331 new deaths; 1.3 new death per 100 000; similar to the previous week's figures), and Japan (192 new deaths; <1 new death per 100 000; +106%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May 2022, data for COVID-19 cases and deaths in Northern Ireland was no longer included in the United Kingdom updates.

^[3] Updates of an outbreak of COVID-19 reported in the Democratic People’s Republic of Korea continue through official media since 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Annex 2. Neutralization Studies of Primary Series and First Booster Vaccine Performance against Omicron Variant of Concern (data as of 27 June 2022)

Abbreviations: HNR=high non-response. Arrows generalize the magnitude of reduction in neutralization against the Omicron sub-lineage relative to the ancestral strain: “↔” indicates <2-fold reduction in neutralization; “↓” indicates 2 to <5-fold reduction; “↓↓” indicates 5 to <10-fold reduction; “↓↓↓” indicates ≥10-fold reduction. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies was used, restricting to studies reporting ≥75% of persons/sera with detectable neutralization titers. HNR indicates a median percent of persons/sera with detectable neutralization titers across all studies of <75%; in these instances, fold-reductions can be biased and, thus are not presented. The number of studies is shown as subscripts. For booster vaccination, only schedules with available results are shown.

Additional notes on Annex 2 table

- Studies contributing to the table are identified from an ongoing review of the preprint and published literature on neutralization of SARS-CoV-2 variants by COVID-19 vaccines.
- Studies that use samples collected more than seven days and less than six months after complete vaccination and that use an ancestral strain as the reference are included in the table.
- Studies of immunocompromised persons are excluded.
- It is important to note that studies vary in population and other methodological considerations, which may in part explain some differences when comparing products between different studies. In addition, the reductions summarized in the table do not incorporate uncertainty intervals around the degree of reductions, which can vary substantially across studies when reported.

COVID-19 Weekly Epidemiological Update

Edition 98, published 29 June 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: Relative vaccine effectiveness](#)
- [WHO regional overviews](#)

Global overview

Data as of 26 June 2022

Globally, the number of weekly cases has increased for the third consecutive week, after a declining trend since the last peak in March 2022. During the week of 20 to 26 June 2022, over 4.1 million new cases were reported, an 18% increase as compared to the previous week (Figure 1). The number of new weekly deaths remained similar to that of the previous week, with over 8500 fatalities reported.

At the regional level, the number of new weekly cases increased in the Eastern Mediterranean Region (+47%), the European Region (+33%), the South-East Asia Region (+32%), and the Region of the Americas (+14%), while it decreased in the African Region (-39%) and the Western Pacific Region (-3%). The number of new weekly deaths increased in the Eastern Mediterranean Region (+22%), the South-East Asia Region (+15%), and the Region of the Americas (+11%), while decreases were observed in the Western Pacific Region (-6%), the European Region (-5%) and the African Region (-1%).

As of 26 June 2022, over 541 million confirmed cases and over 6.3 million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 26 June 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest numbers of new weekly cases were reported from the United States of America (701 855 new cases; +5%), Germany (504 655 new cases; +23%), Brazil (349 791 new cases; +37%), Italy (340 012 new cases; +61%), and China (333 926 new cases; -18%).

The highest numbers of new weekly deaths were reported from the United States of America (1997 new deaths; -2%), Brazil (1313 new deaths; +37%), China (925 new deaths; -11%), the Russian Federation (429 new deaths; -3%), and Italy (355 new deaths; +5%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 26 June 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	1 796 850 (43%)	33%	226 115 754 (42%)	2 259 (26%)	-5%	2 024 722 (32%)
Americas	1 360 367 (33%)	14%	162 064 197 (30%)	4 127 (48%)	11%	2 758 857 (44%)
Western Pacific	799 391 (19%)	-3%	63 605 980 (12%)	1 566 (18%)	-6%	237 209 (4%)
South-East Asia	131 014 (3%)	32%	58 471 132 (11%)	314 (4%)	15%	789 814 (12%)
Eastern Mediterranean	74 016 (2%)	47%	21 948 319 (4%)	83 (1%)	22%	343 485 (5%)
Africa	20 579 (<1%)	-39%	9 107 669 (2%)	203 (2%)	-1%	173 447 (3%)
Global	4 182 217 (100%)	18%	541 313 815 (100%)	8 552 (100%)	3%	6 327 547 (100%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

There continues to be a decline in the number of SARS-CoV-2 sequences submitted to GISAID, as compared to January 2022 when 1 248 906 sequences were submitted. From 27 May to 27 June 2022, 146 183 SARS-CoV-2 sequences were submitted to GISAID. Among these sequences, the Omicron VOC remains the dominant variant circulating globally, accounting for 94% of sequences reported in the past 30 days. Among Omicron sequences, as of epidemiological week 24 (13 to 19 June 2022) BA.2 represents 25%, while BA.2.12.1 represents 11%, BA.4 represents 12%, and BA.5 represents 43%. Comparing the proportion of Omicron sequences submitted during epidemiological weeks 23 (6 to 12 June) and 24, BA.2 declined from 30% to 25%, BA.2.12.1 declined from 18% to 11%, while BA.4 increased from 9% to 12% and BA.5 increased from 28% to 43%.

These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as changes in sampling and sequencing strategies in multiple countries.

Special Focus: Relative vaccine effectiveness

Vaccine effectiveness (VE) is a measure of how well vaccines work in the real world. Most VE studies compare the risk of a clinical outcome among vaccinated persons to the risk among unvaccinated persons, referred to as absolute VE (aVE).

$$aVE = 1 - \frac{\text{risk among vaccinated}}{\text{risk among unvaccinated}} \times 100\%$$

However, as vaccine coverage reaches a high rate (e.g., >90%), the unvaccinated population can become quite different from the vaccinated population in terms of SARS-CoV-2 exposure and/or disease risk, leading to a bias in the aVE results. To help mitigate this bias and compare more similar risk groups, one can compare vaccine effectiveness within the group of vaccinated individuals alone, specifically comparing by the number of doses received. For example, one can compare recipients of one booster dose to recipients of only the primary series, or compare recipients of two booster doses to recipients of one booster dose or the primary series, and so on. This type of comparison is called a relative VE (rVE) and has been done for several vaccines, such as those for influenza.¹ For COVID-19 vaccines, rVE has been reported in studies from multiple countries including Israel, Brazil and Canada.²⁻

4

The relationship between absolute and relative VE can be expressed in the following mathematical terms (using boosted versus primary series as an example), which is demonstrated in Figure 4.

$$rVE = \frac{aVE_{\text{boosted}} - aVE_{\text{primary series}}}{1 - aVE_{\text{primary series}}} \times 100\%$$

Figure 4. Relationship between absolute vaccine effectiveness to relative vaccine effectiveness^a

^aThe figure can be applied to any relative VE comparison (i.e., three doses versus two doses; four versus two doses etc.). In this figure, booster dose versus primary series have been used as an example.

At low aVE of the primary series (whereby primary series recipients are compared to unvaccinated persons), the rVE of the booster dose (whereby booster dose recipients are compared to primary series recipients) approximates the aVE of the booster dose (whereby booster dose recipients are compared to unvaccinated persons). However, at high aVE of the primary series, the rVE of the booster dose can vary quite dramatically while the incremental gain in aVE of the booster dose is small.

For example, if the aVE of the primary series is 90%, and the rVE of the booster dose is 50%, then the aVE of the booster dose is 95%. This rVE of 50% makes it appear like a significant increase in protection, but the gain in absolute VE is only 5%. Meanwhile, if the aVE of the primary series is 0%, and rVE of the booster dose is 50%, then the aVE of the booster dose is 50%. The true aVE of the booster dose should always be higher than the rVE, but by how much will depend on the true aVE of the primary series, which is determined by a variety of factors. However, in real-world VE studies, this is not always the case due to issues such as confounding bias (e.g. due to behavioral differences, history of a prior SARS-CoV-2 infection) and uncertainty of the estimates.

Figure 5. Absolute and relative vaccine effectiveness of the first booster dose against Omicron VOC^a

^a Labels on y-axis indicate: [reference number], country, population, vaccine. Reference numbers refer to study numbers in Table 2 of the *COVID-19 Vaccine Effectiveness Results Summary Table* found at <https://view-hub.org/resources>.

A few studies have evaluated both the aVE and the rVE of the booster dose. The results of these evaluations are summarized in Figure 5. Because persons in the comparison group potentially have some vaccine-induced immunity, the rVE is lower or equal to the aVE of the booster dose. If investigators do not provide the aVE of the booster dose, then one cannot calculate it from the rVE alone. One would need both the rVE and the aVE of the primary series at the same time in the same population to calculate the aVE of the booster dose.

The rVE provides a way to quantify the additional preventive benefit of a booster dose versus a primary series. The rVE must be interpreted with the understanding that the comparison group has potentially some residual protection

from the vaccine. Interpreting the rVE requires knowing the population and vaccine being evaluated, the timing of the last dose, the clinical outcome, and the epidemiologic situation, including the circulating SARS-CoV-2 variants. Because these are context and time-specific, one cannot use an aVE of the primary series from one study to calculate the aVE of a booster dose in another study. Furthermore, the rVE of a given vaccine cannot be compared across studies as rVE is dependent on aVE, signifying that averted events can vary widely from study to study.⁵

Second booster dose VE

To date, nine studies have assessed the rVE against the Omicron VOC over time of a second booster vaccine dose relative to either the first booster dose or the primary series. In five studies evaluating the protection of mRNA boosters against COVID-19 *severe disease* (hospitalization, ICU admission, and/or death), the rVE of a second mRNA booster dose compared to the first booster dose ranged from 40% to 86.5% (Table 2). The follow-up time was limited in all studies. Only one study was able to calculate the absolute and relative VE of a second booster dose against severe disease, finding an aVE of the second booster dose of 86%, an aVE of the first booster dose of 77%, and an rVE of 40%.² Also presented is the absolute risk reduction to show the impact of the addition of a second booster dose.

Table 2. Studies evaluating the relative vaccine effectiveness (VE) against SARS-CoV-2-specific outcomes of the second booster dose (data as of 27 June 2022)

Study	Country	Population studied	Vaccine Evaluated	Infection with SARS-CoV2	Severe Disease/Mortality with COVID-19			
				Relative VE against Infection (95% CI)	Relative VE against Severe disease (95% CI)	Rate among comparator group	Rate among 2 nd booster dose recipients	Rate difference
Cohen et al⁶	Israel	HCWs	Pfizer-BioNTech-Comirnaty	44% (37-50%) ≥7 days after second booster dose versus ≥4 months after first [†] booster dose				
Regev-Yochay et al⁷	Israel	HCWs	Pfizer-BioNTech-Comirnaty	30% (-9 to 55%) ≥7 days after second booster dose versus ≥4 months after first booster dose				
			Moderna-Spikevax	11% (-43 to 44%) ≥7 days after second booster dose versus ≥4 months after first booster dose				
Amir et al⁴	Israel	≥60 years	Pfizer-BioNTech-Comirnaty		89% (87-91%) 0-2 months after second booster dose versus ≥4 months after primary series.	11.6 (10.6-12.9) / 100 000 person days at risk	1.3 (1.1-1.4) / 100 000 person days at risk	10.3 cases / 100 000 person days at risk
Arbel et al⁸	Israel	≥60 years	Pfizer-BioNTech-Comirnaty		78% (72-83%) ≥7 days after second booster dose versus ≥4 months after first booster dose (mortality)	99.2 / 100 000 persons at risk	28 / 100 000 persons at risk	71.2 / 100 000 persons at risk*

<u>Bar-On et al</u> ⁹	Israel	≥60 years	Pfizer-BioNTech-Comirnaty	52% (50-52%) 15-21 days after second booster dose versus ≥4 months after first booster dose	66% (57-72%) 15-21 days after second booster dose versus ≥4 months after first booster dose	5.5 (5.2-5.9) / 100 000 person days at risk	2.3 (1.9-2.8) / 100 000 person days at risk	3.2 (2.7-3.7) / 100 000 person days at risk
				9% (0-17%) 50-56 days after second booster dose versus ≥4 months after first booster dose	77% (62-86%) 36-42 days after second booster dose versus ≥4 months after first booster dose	5.5 (5.2-5.9) / 100 000 person days at risk	1.3 (0.8- 2.2) / 100 000 person days at risk	4.2 (3.4–4.9) / 100 000 person-days at risk

WHO regional overviews:

Epidemiological week 20-26 June 2022**

African Region

The African Region reported a decline in the number of new weekly cases, with over 20 000 new cases reported, a 39% decrease as compared to the previous week. Fourteen (29%) countries reported an increase in the number of new cases of 20% or greater, with some of the greatest proportional increases seen in Equatorial Guinea (44 vs six new cases; +633%), Gabon (82 vs 31 new cases; +165%) and the Seychelles (184 vs 88 new cases; +109%). The countries that reported the highest numbers of new cases were South Africa (6843 new cases; 11.5 new cases per 100 000 population; -14%), Ethiopia (3092 new cases; 2.7 new cases per 100 000; -40%), and Kenya (2859 new cases; 5.3 new cases per 100 000; +21%).

The number of new weekly deaths in the Region was similar as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from South Africa (133 new deaths; <1 new death per 100 000 population; +10%), Democratic Republic of the Congo (17 new deaths; <1 new death per 100 000; +325%), and Zimbabwe (15 new deaths; <1 new death per 100 000; +15%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported an increase in the number of new weekly cases, with over 1.3 million new weekly cases, a 14% increase as compared to the previous week. Sixteen (29%) countries reported increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Canada (15 051 vs 6515 new cases; +131%), the Falkland Islands (Malvinas) (51 vs 23 new cases; +122%) and Bolivia (Plurinational State of) (5485 vs 2617 new cases; +110%). The highest numbers of new cases were reported from the United States of America (701 855 new cases; 212.0 new cases per 100 000; +5%), Brazil (349 791 new cases; 164.6 new cases per 100 000; +37%), and Mexico (76 407 new cases; 59.3 new cases per 100 000; +47%).

The number of new weekly deaths in the Region increased by 11% as compared to the previous week, with over 4100 new deaths reported. The highest numbers of new deaths were reported from the United States of America (1997 new deaths; <1 new death per 100 000; -2%), Brazil (1313 new deaths; <1 new death per 100 000; +37%), and Chile (159 new deaths; <1 new death per 100 000; +6%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 74 000 new weekly cases, representing a 47% increase as compared to the previous week. Ten (45%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Iraq (6237 vs 2210 new cases; +182), Tunisia (2277 vs 886 new cases; +157%), and Pakistan (1652 vs 718 new cases; +130%). The highest numbers of new cases were reported from Morocco (17 729 new cases; 48.0 new cases per 100 000; +84%), Bahrain (12 740 new cases; 748.7 new cases per 100 000; +38%), and the United Arab Emirates (11 139 new cases; 112.6 new cases per 100 000; +15%).

The number of new weekly deaths in the Region increased by 22% as compared to the previous week, with 83 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (20 new deaths; <1 new death per 100 000; +43%), Tunisia (15 new deaths; <1 new death per 100 000; +114%), and Saudi Arabia (13 new deaths; <1 new death per 100 000; -13%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After reporting decreases in the number of new weekly cases since mid-March 2022, an increase has been reported for the third consecutive week in the European Region, with over 1.8 million new cases reported, a 33% increase compared to the previous week. Thirty-three (54%) countries in the Region reported increases in new cases of 20% or greater, with the greatest proportional increases observed in Romania (2609 vs 341 new cases; +665%), Spain (118 421 vs 18 757 new cases; +531%) and Kazakhstan (299 vs 112 new cases; +167%). The highest numbers of new cases were reported from Germany (504 655 new cases; 606.8 new cases per 100 000; +23%), Italy (340 012 new cases; 570.1 new cases per 100 000; +61%), and France (331 843 new cases; 510.2 new cases per 100 000; +37%).

Over 2200 new weekly deaths were reported in the Region, a 5% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (429 new deaths; <1 new death per 100 000; -3%), Italy (355 new deaths; <1 new death per 100 000; +5%), and Spain (317 new deaths; <1 new death per 100 000; +45%).

Updates from the [European Region](#)

South-East Asia Region

After the declining trend in new cases observed since mid-January 2022, the South-East Asia Region has reported increases over the last four weeks, with over 131 000 new cases reported, a 32% increase as compared to the previous week. Eight of ten countries (80%) for which data are available showed increases in the number of new cases of 20% or greater, with some of the greatest proportional increases observed in Bangladesh (8846 vs 2212 new cases; +300%), the Maldives (1043 vs 528 new cases; +98%) and Sri Lanka (83 vs 47 new cases; +77%). The highest numbers of new cases were reported from India (93 281 new cases; 6.8 new cases per 100 000; +25%), Thailand (15 111 new cases; 21.6 new cases per 100 000; +7%), and Indonesia (12 376 new cases; 4.5 new cases per 100 000; +63%).

The number of new weekly deaths in the Region increased by 15% as compared to the previous week, with over 300 new deaths reported. The highest numbers of new deaths were reported from India (144 new deaths; <1 new death per 100 000; +53%), Thailand (125 new deaths; <1 new death per 100 000; -6%), and Indonesia (30 new deaths; <1 new death per 100 000; -32%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region continues the decreasing trend observed since mid-May 2022, with over 799 000 new cases reported last week, which is similar to the number of new cases reported during the previous week. Twelve (36%) countries reported increases in new cases of 20% or greater, with some of the largest proportional increases observed in Samoa (346 vs 75 new cases; +361%), French Polynesia (102 vs 60 new cases; +70%) and the Philippines (4376 vs 2738 new cases; +60%). The highest numbers of new cases were reported from China (333 926 new cases; 22.7 new cases per 100 000; -18%), Australia (196 360 new cases; 770.0 new cases per 100 000; +8%), and Japan (109 520 new cases; 86.6 new cases per 100 000; +20%).

The Region reported over 1500 new weekly deaths, representing a 6% decrease as compared to the previous week. The highest numbers of new deaths were reported from China (925 new deaths; <1 new death per 100 000; -11%), Australia (331 new deaths; 1.3 new deaths per 100 000; +6%), and the Republic of Korea (87 new deaths; <1 new death per 100 000; +43%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May 2022, data for COVID-19 cases and deaths in Northern Ireland was no longer included in the United Kingdom updates.

^[3] Updates of an outbreak of COVID-19 reported in the Democratic People’s Republic of Korea continue through official media since 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Global overview

Data as of 19 June 2022

Globally, the number of new weekly cases has continued to decline since the peak in January 2022. During the week of 13 until 19 June 2022, over 3.3 million cases were reported, a 4% decrease as compared to the previous week (figure 1). The number of new weekly deaths declined by 16% as compared to the previous week, with over 7500 fatalities reported.

At the regional level, the number of new weekly cases increased in the South-East Asia Region (+46%), the Eastern Mediterranean Region (+45%), and the European Region (+6%), while it decreased in the other three WHO regions. The number of new weekly deaths increased in the South-East Asia Region (+4%), while decreasing trends were observed in the other five regions.

As of 19 June 2022, over 536 million confirmed cases and over 6.3 million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 19 June 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the United States of America (652 217 new cases; -12%), China (406 401 new cases; -19%), Germany (356 414 new cases; +10%), Brazil (256 034 new cases; -9%), and France (253 322 new cases; +33%). The highest number of new weekly deaths were reported from the United States of America (1 858 new deaths; -13%), China (1 044 new deaths; -13%), Brazil (956 new deaths; -3%), the Russian Federation (443 new deaths; -11%), and Italy (338 new deaths; -24%).

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.¹

Geographic spread and prevalence of VOCs

The Omicron VOC continues to be the dominant variant circulating globally, accounting for nearly all sequences reported to GISAID between 17 May and 17 June 2022. Among Omicron lineages, as of epidemiological week 23 (6 to 12 June 2022), the proportions of BA.2 and its descendent lineages (pooled lineages named BA.2.X) are declining but nonetheless remain dominant, accounting for 36% and 12% respectively (Table 2).

Globally, BA.5 and BA.4 lineages continue to rise in prevalence and have been detected in 62 and 58 countries respectively. BA.2.12.1, which has now been detected in 69 countries, has decreased in prevalence since the previous week. As of week 23, the prevalence of BA.5 is 25% (from previous week 16%), BA.4 is 9% (from previous week 16%) and BA.2.12.1 is 17% (from previous week 31%). BA.4 and BA.5 have a constellation of genetic mutations that differ from BA.2, including a shared mutation at S:L452 which has been associated with higher transmissibility. The rise in prevalence of BA.4 and BA.5 has coincided with a rise in cases in several WHO regions. In some countries, the rise in cases has also led to a surge in hospitalizations and ICU admissions; however, the current evidence available does not indicate a change in severity associated with any of the three Omicron descendent lineages BA.2.12.1, BA.4 and BA.5.

Based on sequence data submitted to GISAID, variant circulation and dynamics differ by country. Multiple countries report co-circulation of BA.2.12.1, BA.4 and BA.5. The prevalence of VOC-LUMs BA.2.9.1, BA.2.11 and BA.2.13 (all carrying the S:L452 mutation) is <1%.

Figure 5 Panel A and B: The number and percentage of SARS-CoV-2 sequences, as of 20 June 2022

Figure 4 Panel A shows the number and Panel B the percentage of all circulating variants since 1 January 2022. Omicron sister-lineages and additional Omicron VOC descendent lineages under further monitoring (VOC-VUM) are shown. BA.1.X and BA.2.X include all BA.1 and BA.2 pooled descendent lineages, except those already shown in the figure above. Source: SARS-CoV-2 sequence data and metadata from GISAID, as of 20 June 2022.

[#]Previously circulating VOC

The blue rows indicate the dominant lineages. The darker grey rows indicate the lineages that are increasing in prevalence, light grey indicate the lineage with decreasing prevalence since last week.

Characteristics of Omicron

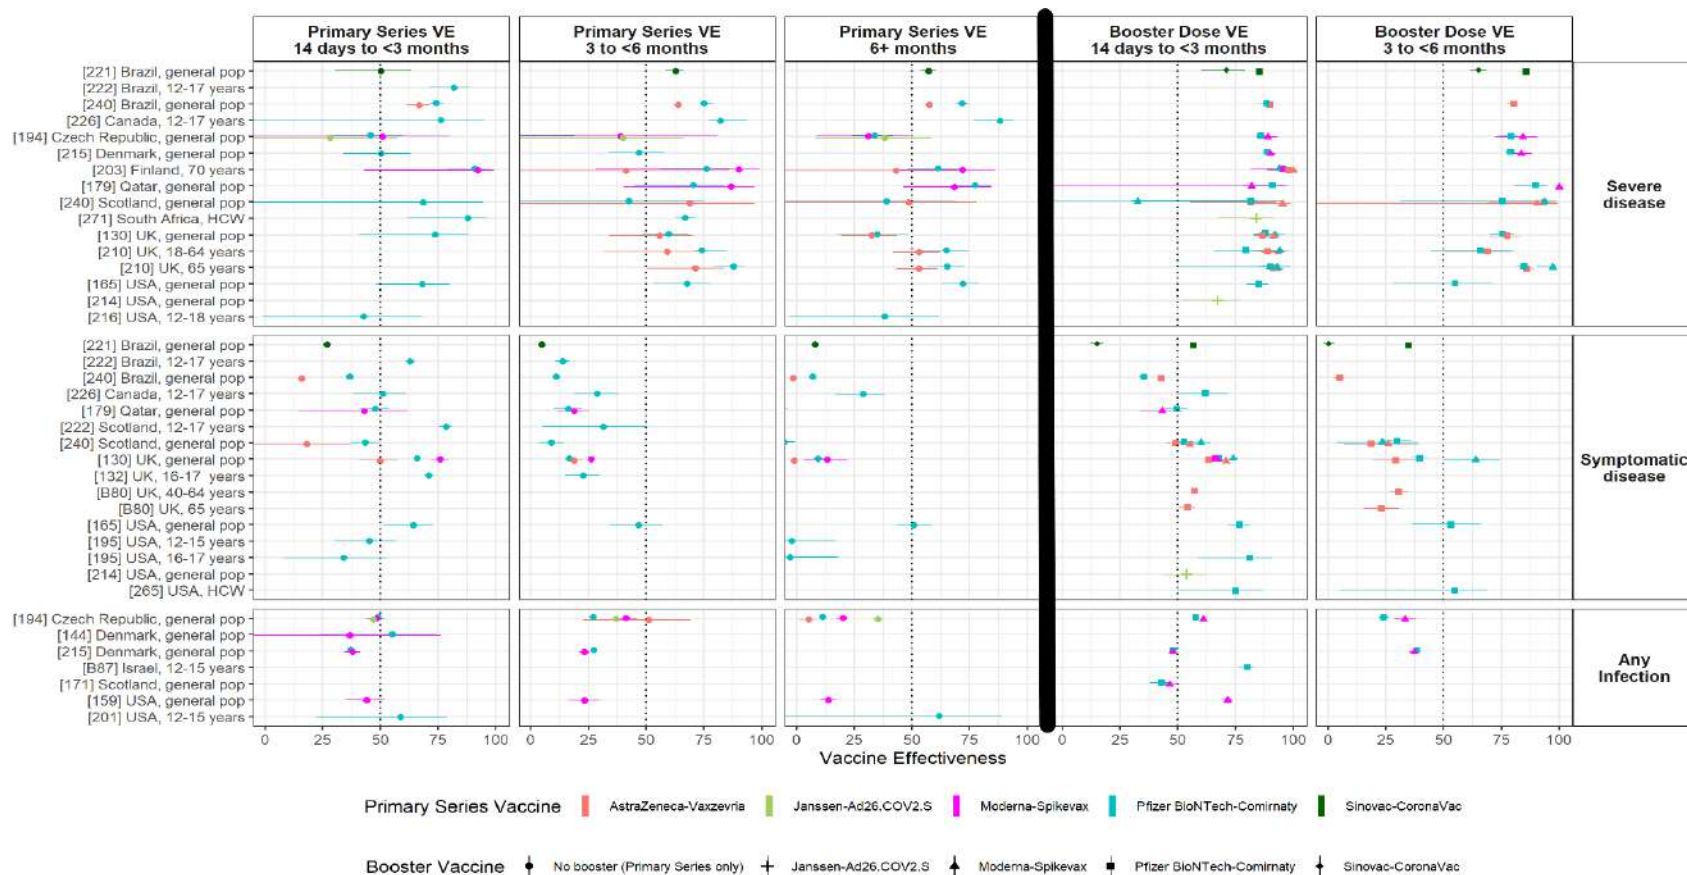

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Table 2 summarizes the phenotypic characteristics of the Omicron VOC and its sublineages for which evidence is available since the [last update on 8 June 2022](#). Some of these studies have not been peer-reviewed and the findings must, therefore, be interpreted with due consideration of this limitation.

Table 2: Summary of phenotypic characteristics* of the Omicron VOC

Public health domain of impact	Omicron (B.1.1.529)	Omicron sublineages			
		BA.1	BA.2	BA.4	BA.5
Transmissibility	Growth advantage and increased transmissibility compared to Delta ⁱ	Lower transmissibility compared to BA.2 ²	Increased transmissibility compared to BA.1 ²	Growth advantage compared to BA.2 ³	Growth advantage over BA.2 ³
Disease severity	Overall evidence suggests lower severity despite contrasting evidence. Earlier studies reported lower severity compared to Delta. ^{4–8} However, more recent studies in different settings reported similar ^{9,10} or increased severity ¹¹ compared to Delta. ^{4–8,12–13}	No difference in disease severity compared to BA.2 ¹⁴	No difference in disease severity compared to BA.1 ¹⁴	Currently available evidence does not suggest a difference in disease severity compared to BA.1 ¹⁵	Currently available evidence does not suggest a difference in disease severity compared to BA.1 ^{16,17}
Risk of reinfection	Reduced risk of Omicron reinfection among individuals previously infected with a different SARS-CoV-2 variant compared to naïve individuals ^{18,19}	Reduced risk of reinfection with BA.1 following infection with BA.2 ²⁰	Reduced risk of reinfection with BA.2 following infection with BA.1 ²⁰	No specific data available	No specific data available
Impact on antibody responses	Reduction in neutralizing activity reported as compared to other VOCs ^{21–23}	Lower neutralising antibody titers compared to the index virus ²²	Lower neutralising antibody titers compared to the index virus ²²	Lower neutralising antibody titres (7.6-fold) compared to BA.1 ^{24–26}	Lower neutralising antibody titres (7.5-fold) compared to BA.1 ^{24,26}
Impacts on diagnostics	PCR assays that include multiple gene targets maintain their accuracy to detect Omicron ²⁷ ; S gene target failure/positivity (SGTF) may be a proxy for screening. Limited to no impact on sensitivity of Ag-RDTs observed ^{28–31}	S gene target failure.	The majority will be S gene target positive (SGTP).	S gene target failure.	S gene target failure.
Impact on treatment	No difference in the effectiveness of antiviral agents (polymerase and protease inhibitors) against the Omicron variant ³² . Conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduced effectiveness of other monoclonal antibodies ^{33–36}	Reduced efficacy of casirivimab-imdevimab against BA.1 ³⁷	Reduced neutralising activity of sotrovimab ³⁷ , casirivimab and imdevimab against BA.2 ³⁸	Reduced neutralising activity of casirivimab and imdevimab ³⁸	Reduced neutralising activity of casirivimab and imdevimab ³⁸
Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant				

ⁱ Similar methodology used as Reference¹

Figure 6. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

Abbreviations: pop=population; HCW=healthcare workers. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers, country, and study population. Reference numbers identify the study and link to the [summary table](#) of VE effectiveness studies on [view-hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes severe disease, hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, nine point estimates for the primary series with confidence intervals below 0 are not shown in the Omicron plot: two estimates from reference #144 against infection at 3 to <6 months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), two estimates from reference #179 against symptomatic disease at 6+ months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), and five estimates from reference #240 (one AstraZeneca-Vaxzevria estimate at 3 to <6 months; three AstraZeneca-Vaxzevria estimates and one Pfizer BioNTech estimate at 6+ months).

Figure 6 summarizes the impact of the Omicron variant on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Additional information on vaccine performance against VOCs can also be found in Annex 4. Since the last [update](#), one new study assessing absolute vaccine effectiveness of three doses of Pfizer BioNTech-Comirnaty among healthcare workers in the United States of America has been added to the figure.³⁹ In addition, a study evaluating VE of two doses of Janssen-Ad26.COVS.2 against hospitalization among healthcare workers in South Africa that had been previously included in the figure has now been published. The study has provided additional VE estimates for two doses of Pfizer-BioNTech-Comirnaty, which have been added to the figure.⁴⁰

Interpretation of the results of absolute VE for the Omicron variant

To date, 23 studies from ten countries (Brazil, Canada, Czech Republic, Denmark, Finland, Israel, Qatar, South Africa, the United Kingdom and the United States of America) have assessed the duration of protection of five vaccines against the Omicron variant (six studies assessed VE of primary series vaccination only, three assessed VE of booster vaccination only, and 14 assessed both). Findings from these studies show reduced VE of COVID-19 primary series vaccines against the Omicron variant for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for the other four VOCs. Importantly though, VE estimates against the Omicron variant remain higher for *severe disease* than the other outcomes, in the majority of studies. Booster vaccination substantially improves VE for all outcomes and for all combinations of schedules with estimates available for both primary series and booster vaccination. VE declines more with time after booster vaccination for symptomatic disease and infection than it does for severe disease; however, studies that assess VE of booster vaccination beyond six months are needed to evaluate longer duration of protection.

For *severe disease*, within the first three months of primary series vaccination, seven of 13 (54%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty) were $\geq 70\%$. Of the two studies available for vector vaccines, one reported a VE of $<70\%$ for AstraZeneca-Vaxzevria, and the other reported a VE of $<50\%$ for Janssen-Ad26.COVS.2. One study was available for inactivated vaccines (Sinovac-CoronaVac), reporting a VE of 50%. Beyond three months after vaccination, thirteen of 29 (45%) VE estimates for the mRNA vaccines were $\geq 70\%$ while 20 (69%) were $\geq 50\%$; one of the 12 (8%) VE estimates for AstraZeneca-Vaxzevria was $\geq 70\%$ while eight (67%) were $\geq 50\%$; neither of the two estimates for the other vector-based vaccine, Janssen-Ad26.COVS.2, were $\geq 50\%$. The two available VE estimates beyond three months of vaccination for Sinovac-CoronaVac were $\geq 50\%$.

Booster vaccination improved VE against *severe disease* in all studies in which it was assessed. There were 33 estimates evaluated an mRNA booster, two estimates for a booster dose of Janssen-Ad26.COVS.2, and one estimate for a booster dose of Sinovac-CoronaVac. Across the datasets, only one estimate for a booster dose of Pfizer BioNTech-Comirnaty and one estimate for a booster dose of Janssen-Ad26.COVS.2 were below 70% between 14 days and three months of receipt of a booster dose. At three to six months post mRNA booster, 17 of 20 (85%) estimates showed VE $\geq 70\%$ (an mRNA vaccine was given as the primary series in 13 of the 20 estimates while AstraZeneca-Vaxzevria and Sinovac-CoronaVac were given as the primary series for six and one of the twenty estimates, respectively).

VE estimates against *symptomatic disease* and *infection* within the first three months of primary series vaccination were lower than against severe disease, and VE decreased more substantially over time. For *symptomatic disease* within the first three months of primary series vaccination, three of 13 (23%) VE estimates for the mRNA vaccines were $\geq 70\%$ and seven (54%) were $\geq 50\%$; none of the three VE estimates for AstraZeneca-Vaxzevria nor the single estimate for Sinovac (CoronaVac) were above 50%. Beyond three months after vaccination, one of the 29 (3%) VE

estimates were $\geq 50\%$ (21 estimates evaluated mRNA vaccines, six evaluated AstraZeneca-Vaxzevria, and two evaluated Sinovac-CoronaVac). mRNA booster vaccination after completion of a primary series of an mRNA vaccine, AstraZeneca-Vaxzevria, or Sinovac-CoronaVac, improved VE against *symptomatic disease*, with five of 21 (24%) VE estimates $\geq 70\%$ and 16 (76%) estimates $\geq 50\%$ between 14 days and three months post booster. However, booster dose protection declined with time since vaccination with only two of 13 (15%) available estimates indicating a VE of $\geq 50\%$ at three to six months following receipt of an mRNA booster dose. Neither the single estimate for a booster dose of AstraZeneca-Vaxzevria nor the single estimate for a booster dose of Sinovac-CoronaVac three to six months post vaccination was above 50%. VE against *infection* showed a similar pattern as that against *symptomatic disease*.

WHO regional overviews:

Epidemiological week 13-19 June 2022**

African Region

The African Region reported 22 000 new cases, a 21% decrease as compared to the previous week. Eleven (22%) countries reported an increase in the number of new cases of 20% or greater, with some of the greatest proportional increases seen in Senegal (51 vs 17 new cases; +200%), South Sudan (36 vs 18 new cases; +100%) and Mozambique (758 vs 392 new cases; +93%). The countries that reported the highest numbers of new cases were South Africa (7978 new cases; 13.5 new cases per 100 000 population; -24%), Ethiopia (3488 new cases; 3.0 new cases per 100 000; -9%), and Kenya (2370 new cases; 4.4 new cases per 100 000; +83%).

The number of new weekly deaths in the Region decreased by 24% as compared to the previous week, with over 150 new deaths reported. The highest numbers of new deaths were reported from South Africa (121 new deaths; <1 new death per 100 000 population; -26%), Uganda (eight new deaths; <1 new death per 100 000; +167%), and Zimbabwe (eight new deaths; <1 new deaths per 100 000; -27%).

Updates from the [African Region](#)

Region of the Americas

After reporting increases in the number of new weekly cases observed since mid-April 2022, the Region of the Americas reported over 1.1 million new cases, a 9% decrease as compared to the previous week. However, fourteen (25%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Turks and Caicos Islands (29 vs 12 new cases; +142%), Saint Kitts and Nevis (73 vs 39 new cases; +87%) and Paraguay (1384 vs 776 new cases; +78%). The highest numbers of new cases were reported from the United States of America (652 217 new cases; 197.0 new cases per 100 000; -12%), Brazil (256 034 new cases; 120.5 new cases per 100 000; -9%), and Chile (73 455 new cases; 384.3 new cases per 100 000; +6%).

The number of new weekly deaths in the Region decreased by 11% as compared to the previous week, with over 3400 new deaths reported. The highest numbers of new deaths were reported from the United States of America (1858 new deaths; <1 new death per 100 000; -13%), Brazil (956 new deaths; <1 new death per 100 000; -3%), and Chile (150 new deaths; <1 new death per 100 000; +24%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 48 000 new weekly cases, representing a 45% increase as compared to the previous week. Fourteen (63%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Iraq (2210 vs 1080 new cases; +105), Morocco (9628 vs 5184 new cases; +86%) and Oman (327 vs 194 new cases; +69%). The highest numbers of new cases were reported from the United Arab Emirates (9651 new cases; 97.6 new cases per 100 000; +63%), Morocco (9628 new cases; 26.1 new cases per 100 000; +86%), and Bahrain (9227 new cases; 542.3 new cases per 100 000; +41%).

The number of new weekly deaths in the Region decreased by 2% as compared to the previous week, with 61 new deaths reported. The highest numbers of new deaths were reported from Saudi Arabia (15 new deaths; <1 new death per 100 000; similar to the previous week's figures), the Islamic Republic of Iran (14 new deaths; <1 new death per 100 000; -33%), and Tunisia (seven new deaths; <1 new death per 100 000; similar to the previous week's figure).

Updates from the [Eastern Mediterranean Region](#)

European Region

After reporting decreases in the number of new weekly cases since mid-March 2022, a slight increase has been reported in the last two weeks in the European Region, with over 1.2 million new cases reported this week, a 6% increase compared to the previous week. Twenty-one (34%) countries in the Region reported increases in new cases of 20% or greater, with the greatest proportional increases observed in the Isle of Man (570 vs 153 new cases; +272%), Uzbekistan (370 vs 140 new cases; +164%) and Kosovo^[1] (93 vs 37 new cases; +151%). The highest numbers of new cases were reported from Germany (356 414 new cases; 428.6 new cases per 100 000; +10%), France (253 322 new cases; 389.5 new cases per 100 000; +33%), and Italy (210 840 new cases; 353.5 new cases per 100 000; +47%).

With just under 2000 new weekly deaths, a 26% decrease as compared to the previous week, the Region reports a decreasing trend since early February 2022. The highest numbers of new deaths were reported from the Russian Federation (443 new deaths; <1 new death per 100 000; -11%), Italy (338 new deaths; <1 new death per 100 000; -24%), and France (272 new deaths; <1 new death per 100 000; +6%).

Updates from the [European Region](#)

South-East Asia Region

After the declining trend in new cases observed since mid-January 2022, the Region has reported an increase in the last three weeks, with over 99 000 new cases reported this week, a 46% increase as compared to the previous week. Six (60%) countries showed increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Bangladesh (2212 vs 492 new cases; +350%), Maldives (369 vs 160 new cases; +131%) and Indonesia (7587 vs 3688 new cases; +106%). The highest numbers of new cases were reported from India (74 675 new cases; 5.4 new cases per 100 000; +65%), Thailand (14 181 new cases; 20.3 new cases per 100 000; -22%), and Indonesia (2.8 new cases per 100 000).

The number of new weekly deaths increased by 4% as compared to the previous week, with over 273 new deaths reported. The highest numbers of new deaths were reported from Thailand (133 new deaths; <1 new death per 100 000; -18%), India (94 new deaths; <1 new death per 100 000; +36%), and Indonesia (44 new deaths; <1 new death per 100 000; +57%).

Updates from the [South-East Asia Region](#)^[3]

Western Pacific Region

With over 820 000 new cases reported last week, the Western Pacific Region continues the decreasing trend that has been observed for the past month. This represents a 16% decline in new cases as compared to the previous week. Seven (21%) countries reported increases in new cases of 20% or greater, with the largest proportional increases observed in Fiji (163 vs 41 new cases; +298%), Northern Mariana Islands (Commonwealth of the) (79 vs 37 new cases; +114%) and the Philippines (2738 vs 1587 new cases; +73%). The highest numbers of new cases were reported from China (406 401 new cases; 27.6 new cases per 100 000; -19%), Australia (181 980 new cases; 713.7 new cases per 100 000; -6%), and Japan (91 491 new cases; 72.3 new cases per 100 000; -27%).

The Region reported over 1600 new weekly deaths, representing a 11% decrease as compared to the previous week. The highest numbers of new deaths were reported from China (1044 new deaths; <1 new death per 100 000; -13%), Australia (311 new deaths; 1.2 new deaths per 100 000; +5%), and Japan (144 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Monthly Operational Update

The [Monthly operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this edition of the COVID-19 Monthly Operational Update, highlights of country-level actions and WHO support to countries include:

- WHO Country Office and Ministry of Health Türkiye lead the development of a national genomic surveillance strategy: 24–26 June 2022 in Izmir, Türkiye
- The United Republic of Tanzania hosts the first simulation exercise in East Africa since the onset of the COVID-19 pandemic, to improve readiness to health emergencies at points of entry
- Empowering indigenous women as ‘agents of change’: WHO supports Ecuador to engage community stakeholders as part of its COVID-19 response strategy
- 15 tonnes of lifesaving COVID-19 supplies arrive in Samoa
- The Syrian Arab Republic’s coastal areas takes COVID-19 vaccination campaign to a new level
- Myanmar: learning from COVID-19 to prepare for influenza
- WHO/Europe carried out an Intra-Action Review in Azerbaijan, identifying challenges and best practices from the response to COVID-19
- PAHO/WHO supports the Plurinational State of Bolivia to introduce and expand oxygen therapy for COVID-19 patients
- Strengthening Yemen’s response to COVID-19 and the delivery of essential health services
- Preparing for future outbreaks with free online courses on 28 diseases through OpenWHO
- “The Story of Coronavirus”: an animated video to understand COVID-19 transmission
- WHO Scientific Advisory Group for the Origins of Novel Pathogens (SAGO) released its first preliminary report
- WHO holds a global consultation entitled “Crafting the Mosaic”: Resilient surveillance systems for respiratory viruses of pandemic potential
- Global Lead Coordinator for COVID-19 Vaccine Delivery Partnership visits Malawi
- Updated WHO guidance and publications

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May, data for COVID-19 cases and deaths in Northern Ireland was no longer included in the United Kingdom updates (see here for the official announcement).

^[3] Updates of an outbreak of COVID-19 reported in the Democratic People’s Republic of Korea continue through official media since 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Annex 2. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the Table 3.

Annex 3. Methods for Figure 6

- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when Omicron was the predominant circulating variant. Only studies providing VE estimates of individual vaccines are included in the plot (studies assessing combined VE of more than one vaccine are excluded). In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.
- For the primary series VE, estimates are only included in the plot for studies that report absolute VE for more than one time period for an individual vaccine. Thirteen studies of VE against Omicron provided only a single cumulative VE estimate for an individual vaccine, which due to varying lengths of time since vaccination are difficult to interpret due to the marked waning of VE over time with omicron.

Annex 4. Summary of Primary Series Vaccine Performance against Variants of Concern
(VE data as of 16 June 2022; Neutralization data as of 15 June 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺									Vaccines without WHO EUL ⁺	
	AstraZeneca-Vaxzevria/ SII - Covishield	Beijing CNBG-BBIBP-CorV	Bharat-Covaxin	Cansino - Convidecia	Janssen- Ad26.COV 2.S	Moderna- mRNA-1273	Novavax- Nuvaxovid/ SII - Covavax	Pfizer BioNTech- Comirnaty	Sinovac- CoronaVac	Anhui ZL- Recombinant	Gamaleya- Sputnik V

Neutralization	↓↓↓ ₇	↓to↓↓↓ ₄	↓↓ ₁	-	↓to↓↓↓ ₄	↓↓↓ ₁₈	-	↓↓↓ ₄₇	5	-	↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

COVID-19 Weekly Epidemiological Update

Edition 96, published 15 June 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: WHO Mass Gatherings Global Event Database Analysis](#)
- [WHO regional overviews](#)

Global overview

Data as of 12 June 2022

Globally, the number of new weekly cases has continued to decline since a peak in January 2022. During the week of 6 until 12 June 2022, over 3.2 million cases were reported, similar to the number reported during the previous week (figure 1).

After five weeks of decline, the number of new weekly deaths has risen again, with over 8700 fatalities reported, a 4% increase as compared to the previous week.

At the regional level, the number of new weekly cases increased in the Eastern Mediterranean Region (+58%), in the South-East Asia Region (+33%) and in the Region of the Americas (+13%), while it decreased in the other three WHO regions.

The number of new weekly deaths increased in the Region of the Americas (+21%) and Western Pacific Region (+17%), while decreasing trends were observed in the other four regions.

As of 12 June 2022, over 533 million confirmed cases and over 6.3 million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 12 June 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the United States of America (743 723 new cases; +13%), China (501 146 new cases; -5%), Germany (281 706 new cases; +16%), Brazil (279 862 new cases; +29%), and Australia (194 158 new cases; -13%).

The highest number of new weekly deaths were reported from the United States of America (2367 new deaths; +32%), China (1201 new deaths; +32%), Brazil (989 new deaths; +52%), the Russian Federation (500 new deaths; -12%), and Italy (443 new deaths; +17%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 12 June 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 278 169 (39%)	13%	159 473 940 (30%)	4 105 (47%)	21%	2 750 430 (44%)
Western Pacific	970 940 (30%)	-8%	61 985 866 (12%)	1 882 (22%)	17%	233 976 (4%)
Europe	873 103 (27%)	-8%	222 587 925 (42%)	2 208 (25%)	-18%	2 018 528 (32%)
South-East Asia	67 795 (2%)	33%	58 240 686 (11%)	261 (3%)	-25%	789 225 (13%)
Eastern Mediterranean	33 329 (1%)	58%	21 823 732 (4%)	62 (1%)	-32%	342 966 (5%)
Africa	27 097 (1%)	-7%	9 047 715 (2%)	219 (3%)	-11%	173 028 (3%)
Global	3 250 433 (100%)	<1%	533 160 628 (100%)	8 737 (100%)	4%	6 308 166 (100%)

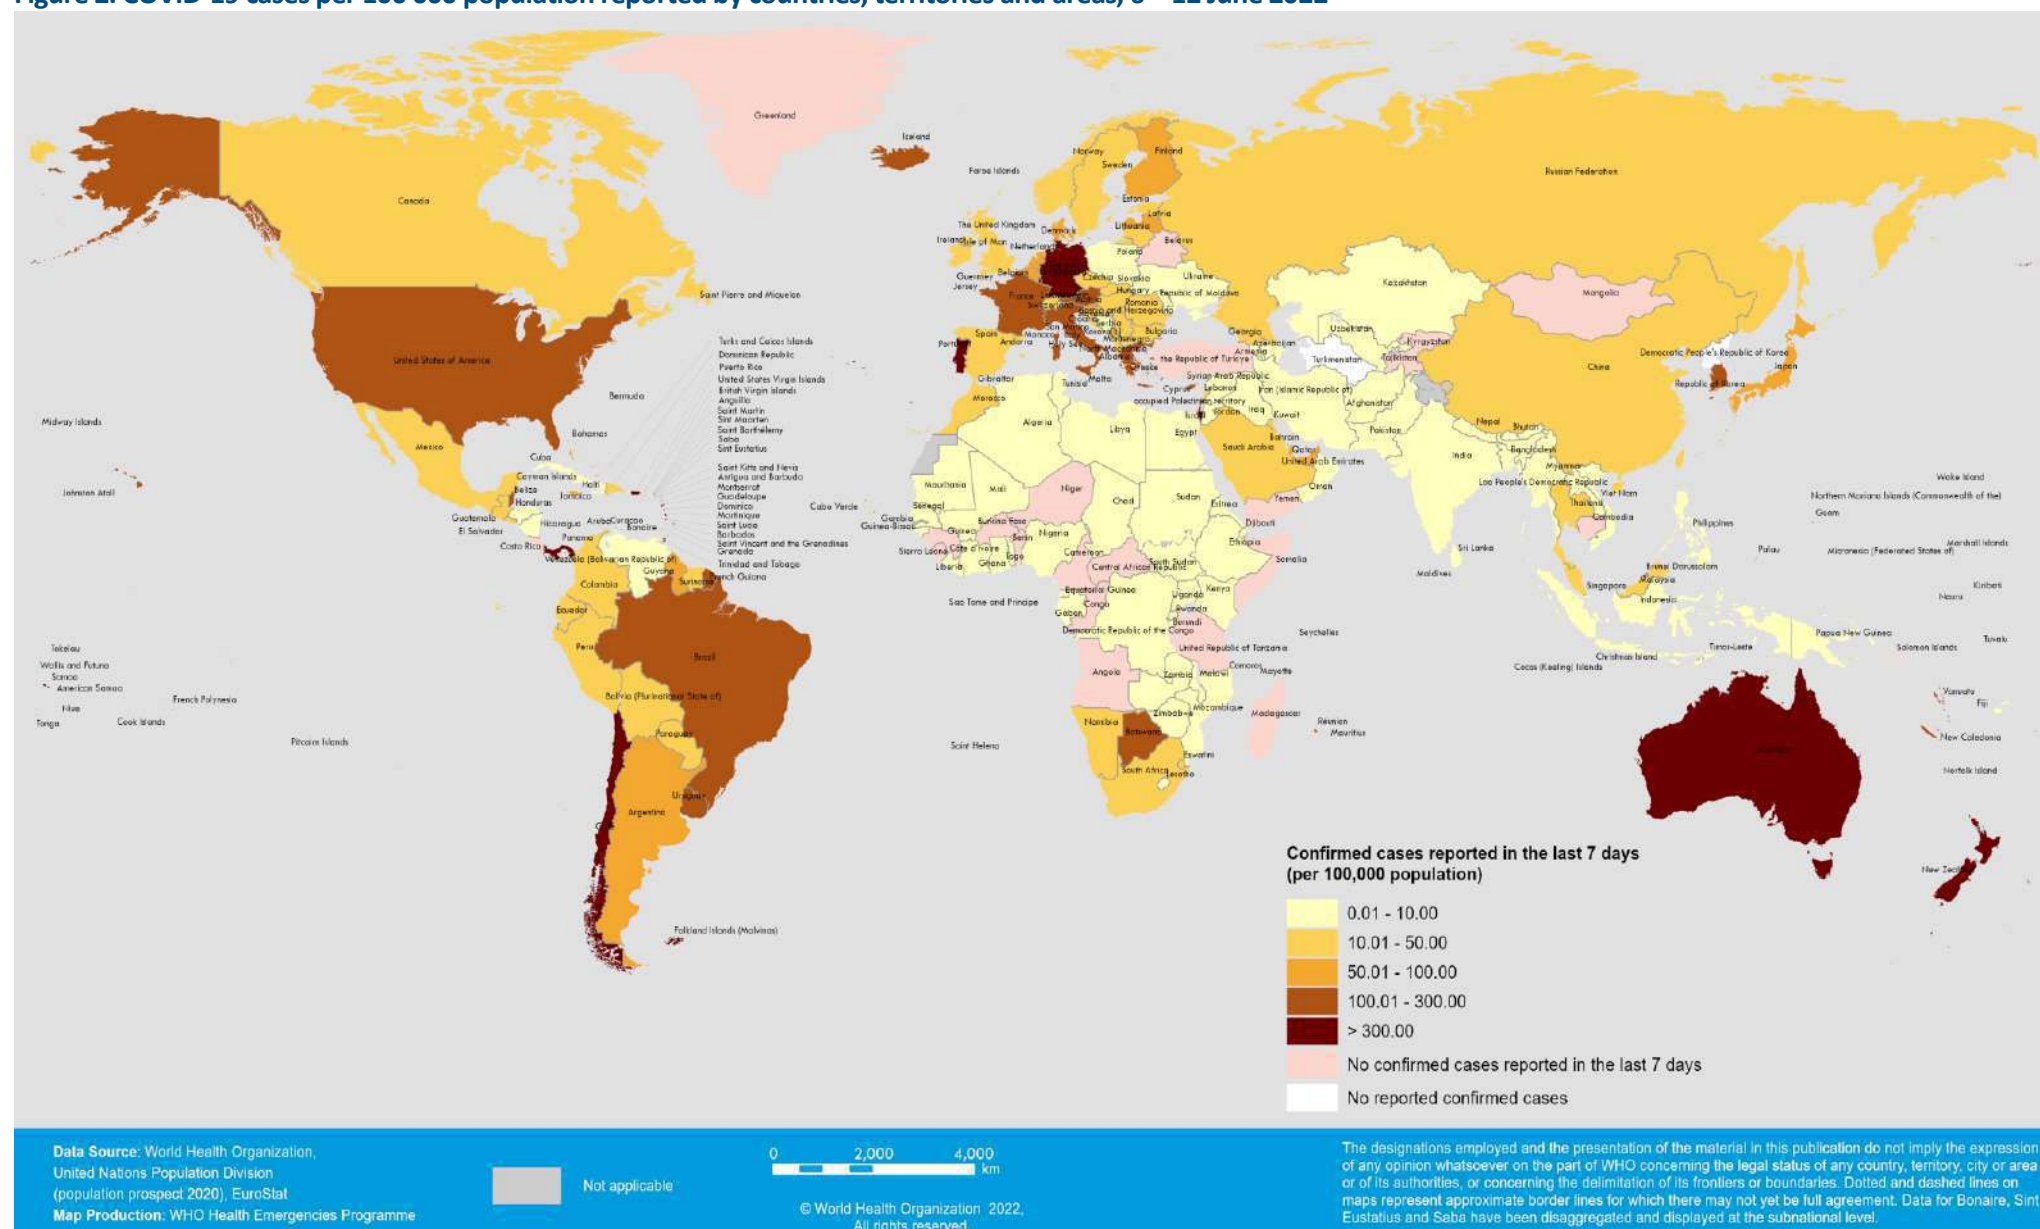

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

Within the last 30 days (13 May to 12 June 2022), 169 940 SARS-CoV-2 sequences were submitted to GISAID. There continues to be a substantial decline in the number of SARS-CoV-2 submissions to GISAID, as compared to the number of sequences submitted during the month of January 2022, when 1 248 906 sequences were submitted to GISAID. The Omicron VOC remains the dominant variant circulating globally, accounting for 97% of sequences reported. Among Omicron lineages submitted to GISAID, BA.2 represents 39%, while BA.2.12.1 represents 28%, BA.5 represents 6%, and BA.4 represents 3%. For epidemiological week 20 (15 to 21 May 2022) and week 21 (22 to 28 May 2022), there was a 4% decline in the number of BA.2 sequences, while there were increases of 4%, 3%, and 2% in BA.5, BA.2.12.1, and BA.4 sequences respectively.

These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as changes in sampling and sequencing strategies in multiple countries.

Special Focus: WHO Mass Gatherings Global Event Database Analysis

Mass Gatherings (MGs) are events characterized by the concentration of people at a specific location for a specific purpose over a set period of time ([WHO, 2015](#)). As such, if inadequately planned and/or managed, mass gatherings have the potential to strain the response resources of the host country or community, also working as amplifiers of disease outbreaks. During the COVID-19 pandemic, the threshold for identifying such events as mass gatherings lowered significantly, as even smaller events and gatherings posed a risk to increased spread of the virus.

Since the beginning of the pandemic, WHO continues to recommend that the decision-making process related to holding, modifying, postponing or cancelling gatherings of any size in the context of the COVID-19 pandemic should rely on a [risk-based approach](#). Such risk assessment exercises should be tailored to the characteristics of the event under consideration and be repeated at regular intervals, throughout the planning period as well as during the gathering, stopping only after the event has ended when local systems have returned to normal. Following such an approach enables a factual and dynamic appraisal of the overall risk associated with the event and its implications, and a timely adaptation of the responseⁱ.

Recognized as a best practice for mass gatherings, public health authorities and event organizers are invited to apply WHO's recommended risk-based approach to decision-making for mass gatherings, tailoring it to the event under consideration.

WHO Mass Gatherings Global Event Database

In January 2020, WHO and its Collaborating Centre for Global Health Security – the Johns Hopkins Bloomberg School of Public Health (JHU) – developed a WHO Mass Gatherings Global Event Database to monitor the impact of the COVID-19 pandemic on mass gathering planning.

Hosts of mass gatherings, as well as all partners involved, are encouraged to enter information on events into an online form ([example data shown](#)) that feeds into the global database and is regularly reviewed and updated by JHU. Between January 2020 and 7 June 2022, the database featured over 5000 mass gatherings, of which 58% have applied WHO's risk-based approach in their decision-making process.

Mass Gatherings Indicators of risk-based approach implementation:

The database has been used to inform [WHO's COVID-19 Strategic Preparedness and Response Plan \(SPRP\)](#) and its associated mass gatherings country-based and event-based indicator(s) on a weekly and monthly basis, as described below (see Table 2).

Since the beginning of the COVID-19 pandemic, the use of risk-based approaches to mass gatherings has increased substantially. As of 7 June 2022, 174 out of 196 (88.7%) countries worldwide, including 90.2% (165/183) of Member States and 75% (9/13) of non-Member States, reported having a mass gathering event being affected by COVID-19 (cancelled, postponed, suspended, otherwise modified or re-opened in post-crisis scenario, i.e. their regular format) as a result of using a risk-based approach to decide if or how a mass gathering should be held.

ⁱ <https://apps.who.int/iris/handle/10665/332235>

The mass gatherings event-level SPRP indicator has remained relatively stable for the last six months at 68%-70% and as of 7 June 2022, 68.5% of events reported having been affected by COVID-19 (Table 2).

Table 2. Mass Gatherings country and event-level SPRP monitoring indicators

<i>Indicator</i>	<i>Description</i>	<i>Percentage</i>	<i>Number</i>
Country-level SPRP indicator	<i>Percentage of <u>countries</u> that reported having at least one mass gathering event affected by COVID-19 (cancelled, postponed, suspended, otherwise modified or re-opened in post crisis scenario) as a result of a risk assessment exercise/risk-based approach.</i>	88.7%	174 out of 196 countries
Event-level SPRP indicator	<i>Percentage of <u>events</u> that were affected by COVID-19 (cancelled, postponed, suspended, otherwise modified or re-opened in post crisis scenario) as a result of a risk assessment exercise/risk-based approach.</i>	68.5 %	2967 out of 4329 events

The breakdown of the mass gatherings country-level SPRP indicator on the use of a risk assessment/risk-based approach for those affected by COVID-19 mass gathering events (88.7% in total) by WHO region and Member States status is described below (see Table 3).

Table 3. Breakdown of the mass gatherings country-level SPRP indicator by WHO Region

WHO Region	Member-States percentage (N)	Non-Member States percentage (N)	WHO Region percentage (N)
Africa	86.7% (39)	100% (1)	87.0% (40)
Americas	87.1% (27)	100% (1)	77.8% (28)
Eastern Mediterranean	81.8% (18)	-	81.8% (18)
Europe	98.1% (53)	100% (2)	98.2% (55)
South-East Asia	81.8% (9)	-	81.8% (9)
Western Pacific	95.0% (19)	100% (5)	96% (24)
Total	90.2% (165 out of 183)	75.0% (9 out of 13)	88.7% (174 out of 196)

Monitoring of mass gathering events status

Monitored modifications to mass gatherings include cancellation, postponement, made virtual, otherwise modified or reopened in post-crisis scenario, held with no modifications, with unknown status, and planning in progress. Data collection for each calendar year includes all events that are happening through the end of December of the current year in order to forecast potential situations of concern. Events that have not yet occurred are recorded as “Planning in progress.” Events for which no data could be found on the event status are recorded as “Unknown”. Figure 4 (below) provides a temporal analysis of decisions made to mass gatherings by host authorities throughout the COVID-19 pandemic.

Figure 4. Monitoring of the mass gathering events status using the WHO Mass Gatherings Global Event Database, 2020- 2022

The majority of mass gatherings were postponed or cancelled in early to mid-2020, most likely as a default measure, but the majority of mass gatherings in late 2020 to 2021 were held in a modified format (i.e. online or hybrid format) as organizers began to embrace the risk-based approach process. The trend also generally follows the decline in mass gatherings coinciding with peaks in incidence of Delta and Omicron VOCs, respectively. The drop in recorded mass gatherings in the database during the latter half of 2022 is likely more attributable to ongoing data collection efforts rather than a true representation of the number of events being held during that time period. However, the proportional rise in events not reporting their status, as compared to reporting modifications or postponements, is being observed. More work is needed to convey the continued risks of SARS-CoV-2 transmission to mass gathering event organizers to encourage the ongoing use and reporting of a risk assessment/risk-based approach (RA/RBA).

Mass gatherings that indicated using a RA/RBA were most often reported to be otherwise modified rather than cancelled or postponed (see Table 4). Fifty-two percent of events (1581 out of 3045) that indicated the use of RA/RBA reported a modification to the event. However, there are still gaps in the data where it could not be determined

whether event organizers used a RA/RBA to make decisions about their events. Over 40% (2134 out of 5244) of all recorded events have not reported whether a RA/RBA was used.

The continuous process of cataloguing and analyzing global mass gatherings demonstrates its value and practicality for the WHO SPRP during the COVID-19 pandemic. Knowing where and when mass gatherings will occur can inform resource mobilization efforts and public health operational response during COVID-19 and other outbreaks.

Additionally, the decision to modify, postpone, or cancel a mass gathering often depends on financial and other considerations alongside health and safety concerns. Applying the risk assessment/risk-based approach can facilitate the delivery of a safe and successful event that, in turn, may yield important psychosocial benefits for participants and spectators and generate revenues for host countries and organizers. However, it is also clear that applying a set of precautionary measures also requires significant levels of human and financial resources. Event organizers, therefore, must account for these factors when planning gatherings of all sizes.

Table 4. Breakdown of usage of a risk assessment for recorded mass gathering events globally (n=5244) as of 7 June 2022

Use of risk assessment	Status of mass gatherings							Total
	Cancelled	Postponed	Made virtual	Otherwise modified	No modifications	Unknown	Planning in progress	
<i>Yes</i>	801 (15.27%)	523 (9.97%)	89 (1.70%)	1581 (30.15%)	4 (0.08%)	16 (0.31%)	31 (0.59%)	3045 (58.07%)
<i>No</i>	34 (0.65%)	7 (0.13%)	0 (0.00%)	19 (0.36%)	3 (0.06%)	2 (0.04%)	0 (0.00%)	65 (1.24%)
<i>Not reported</i>	249 (4.75%)	440 (8.39%)	2 (0.04%)	553 (10.55%)	13 (0.25%)	800 (15.26%)	77 (1.47%)	2134 (40.69%)
Total	1084 (20.67%)	970 (18.50%)	91 (1.74%)	2153 (41.06%)	20 (0.38%)	818 (15.60%)	108 (2.06%)	5244 (100.00%)

WHO regional overviews:

Epidemiological week 6-12 June 2022**

African Region

The African Region reported a decline in the number of new weekly cases for the third consecutive week, with over 27 000 new cases, a 7% decrease as compared to the previous week. However, 13 (27%) countries reported an increase in the number of new cases of 20% or greater, with some of the greatest proportional increases seen in Malawi (89 vs 37 new cases; +141%), Uganda (572 vs 267 new cases; +114%) and Cabo Verde (540 vs 266 new cases; +103%). The countries that reported the highest numbers of new cases were South Africa (10 550 new cases; 17.8 new cases per 100 000 population; -29%), Ethiopia (3829 new cases; 3.3 new cases per 100 000; +54%), and Réunion (1924 new cases; 214.9 new cases per 100 000; -6%)

The number of new weekly deaths in the Region decreased by 11% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from South Africa (164 new deaths; <1 new death per 100 000 population; -4%), Réunion (12 new deaths; 1.3 new deaths per 100 000; +71%), and Zimbabwe (11 new deaths; <1 new deaths per 100 000; +10%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has continued to report increases in case incidence since mid-April 2022, with over 1.2 million new weekly cases, a 13% increase as compared to the previous week. Seventeen (30%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Saint Martin (74 vs 38 new cases; +95%), the British Virgin Islands (137 vs 75 new cases; +83%) and Bolivia (Plurinational State of) (2002 vs 1250 new cases; +60%). The highest number of new cases were reported from the United States of America (743 723 new cases; 224.7 new cases per 100 000; +13%), Brazil (279 862 new cases; 131.7 new cases per 100 000; +29%), and Chile (69 174 new cases; 361.9 new cases per 100 000; +25%).

The number of new weekly deaths in the Region increased by 21% as compared to the previous week, with over 4100 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2367 new deaths; <1 new death per 100 000; +32%), Brazil (989 new deaths; <1 new death per 100 000; +52%), and Canada (199 new deaths; <1 new death per 100 000; -35%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 33 000 new weekly cases, representing a 58% increase as compared to the previous week. Twelve (55%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Morocco (5184 vs 2188 new cases; +137), Kuwait (1701 vs 851 new cases; +100%) and the United Arab Emirates (5909 vs 3269 new cases; +81%). The highest numbers of new cases were reported from Bahrain (6551 new cases; 385.0 new cases per 100 000; +60%), Saudi Arabia (6149 new cases; 17.7 new cases per 100 000; +35%), and the United Arab Emirates (5909 new cases; 59.7 new cases per 100 000; +81%).

The number of new weekly deaths in the Region decreased by 32% as compared to the previous week, with 62 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (21 new deaths; <1 new death per 100 000; -5%), Saudi Arabia (15 new deaths; <1 new death per 100 000; +25%), and Lebanon (eight new deaths; <1 new death per 100 000; -11%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After decreases in the number of new weekly cases observed since mid-March 2022, the European Region reported over 873 000 new cases this week, an 8% increase compared to the previous week. Twenty-one (34%) countries in the Region reported increases in new cases of 20% or greater, with some of the greatest proportional increases observed in the Republic of Moldova (227 vs 34 new cases; +568%), Jersey (308 vs 167 new cases; +84%) and Israel (29 248 vs 16 476 new cases; +78%). The highest numbers of new cases were reported from Germany (281 706 new cases; 338.7 new cases per 100 000; +16%), Italy (143 614 new cases; 240.8 new cases per 100 000; +23%), and France (136 360 new cases; 209.7 new cases per 100 000; -2%).

Over 2200 new weekly deaths were reported, an 18% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (500 new deaths; <1 new death per 100 000; -12%), Italy (443 new deaths; <1 new death per 100 000; +17%), and France (240 new deaths; <1 new death per 100 000; -26%).

Updates from the [European Region](#)

South-East Asia Region

After the declining trend in new cases observed since mid-January 2022, the South-East Asia Region reported over 67 000 new cases, a 33% increase compared to the previous week. Five (50%) countries showed increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Bangladesh (492 vs 216 new cases; +128%), India (45 200 vs 23 774 new cases; +90%) and Indonesia (3688 vs 2385 new cases; +55%). The highest numbers of new cases were reported from India (45 200 new cases; 3.3 new cases per 100 000; +90%), Thailand (18 070 new cases; 25.9 new cases per 100 000; -25%), and Indonesia (3688 new cases; 1.3 new cases per 100 000; +55%).

The number of new weekly deaths in the Region decreased by 25% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from Thailand (163 new deaths; <1 new death per 100 000; -18%), India (69 new deaths; <1 new death per 100 000; -35%), and Indonesia (28 new deaths; <1 new death per 100 000; -32%).

Reports of an outbreak of COVID-19 reported in the Democratic People's Republic of Korea continue through official media on 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Updates from the [South-East Asia Region](#)

Western Pacific Region

With just under 971 000 new cases reported last week, the Western Pacific Region continues the decreasing trend observed for the third consecutive week. This represents an 8% decline in new cases as compared to the previous week. Six (18%) countries reported increases in new cases of 20% or greater, with the largest proportional increases observed in Guam (688 vs 126 new cases; +446%), French Polynesia (160 vs 35 new cases; +357%) and Palau (80 vs 45 new cases; +78%). The highest numbers of new cases were reported from China (501 146 new cases; 34.1 new cases per 100 000; -5%), Australia (194 158 new cases; 761.4 new cases per 100 000; -13%), and Japan (125 577 new cases; 99.3 new cases per 100 000; +3%).

The Region reported over 1800 new weekly deaths, representing a 17% increase as compared to the previous week. The highest numbers of new deaths were reported from China (1201 new deaths; <1 new death per 100 000; +32%), Australia (295 new deaths; 1.2 new deaths per 100 000; +2%), and Japan (144 new deaths; <1 new death per 100 000; -28%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May, data for COVID-19 cases and deaths in Northern Ireland was no longer included in the United Kingdom updates (see here for the official announcement).

COVID-19 Weekly Epidemiological Update

Edition 95, published 8 June 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Monthly operational update on COVID-19 - May 2022](#)

Global overview

Data as of 5 June 2022

Globally, the number of new weekly cases has continued to decline since the peak in January 2022. During the week of 30 May to 5 June 2022, over three million cases were reported, a 12% decrease as compared to the previous week (figure 1). The number of new weekly deaths also continues to decline, with over 7 600 fatalities reported, representing a 22% decrease as compared to the previous week.

At the regional level, the numbers of new weekly cases increased in the Eastern Mediterranean Region (+19%) and South-East Asia Region (+1%), while they decreased in the other four WHO regions. The number of new weekly deaths increased in the Western Pacific Region (+7%), while decreasing trends were observed in the other five regions.

As of 5 June 2022, over 529 million confirmed cases and over six million deaths have been reported globally. These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 5 June 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the United States of America (657 268 new cases; -11%), China (528 432 new cases; -8%), Australia (221 935 new cases; -25%), Brazil (216 334 new cases; +36%), and Germany (215 955 new cases; +16%).

The highest number of new weekly deaths were reported from the United States of America (1 703 new deaths; -33%), China (910 new deaths; +57%), Brazil (652 new deaths; -21%), the Russian Federation (565 new deaths; -7%), and Italy (380 new deaths; -39%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 5 June 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

The Omicron VOC continues to be the dominant variant circulating globally, accounting for nearly all sequences reported to GISAID in the last 30 days. Due to very low circulation among sequences submitted to GISAID in the last three months, Delta is now categorized by WHO as a 'previously circulating VOC,' in the same way that Alpha, Beta and Gamma are categorized. Importantly however, this does not imply that previously circulating VOCs cannot resurge in the future and WHO will continue to monitor using available data.

Among Omicron lineages, as of epidemiological week 20 (15 to 21 May 2022), BA.2 and its descendent lineages (pooled lineages named BA.2.X) are declining but remain dominant, accounting for 44% and 19% respectively (figure 4, Table 2). Several variants with preliminary evidence of a growth advantage over other Omicron lineages show a global prevalence of <1% and are no longer rising, namely BA.2.11, BA.2.13, and BA.2.9.1. These lineages have in common the acquisition of a mutation at the locus S:L452X. Former dominant Omicron lineages BA.1, BA.1.1, BA.1.X and BA.3 sublineages have declined to <1%.

Globally, BA.2.12.1, BA.5, and BA.4 variants are rising in prevalence. As of week 20, BA.2.12.1 (detected in 53 countries) has reached a prevalence of 28%, a prevalence that may be largely attributed to an initial rapid increase in the Region of the Americas. BA.5 (detected in 47 countries) and BA.4 (detected in 42 countries) account for 4% and 2% of circulating variants, respectively. All three variants carry the signature mutation at locus S:L452 that is thought to confer greater transmissibility through higher cell fusogenicity and immune escape characteristics. Accumulating evidence from several countries indicates that there has been no observed increase in severity associated with BA.5 and BA.4.¹ No evidence is available at the current time on disease severity associated with BA.2.12.1.

As for the recombinant variants of SARS-CoV-2 detected in early 2022, including recombinants of known VOCs, a few had characteristics indicative of potential for increased transmissibility; however, this did not translate into a wide spread. The number of SARS-CoV-2 recombinant sequences submitted to GISAID which were being monitored by WHO or which showed an initial rise in the number of sequences reported (XE, XD and XF) continues to decline weekly, now representing <0.1% of sequences submitted during week 20.

Figure 4 Panel A and B: The number and percentage of SARS-CoV-2 sequences, as of 4 June 2022

Figure 4 Panel A shows the number and **Panel B** the percentage of all circulating variants since 1 January 2022. Omicron sister-lineages and additional Omicron VOC descendent lineages under further monitoring (VOC-VUM) are shown. BA.1.X and BA.2.X include all BA.1 and BA.2 pooled descendent lineages, except those already shown in the figure above. Source: SARS-CoV-2 sequence data and metadata from GISAID, as of 4 June 2022.

Table 2: Relative proportions of Omicron lineages over the last four weeks by specimen collection date

Lineage	Countries	Sequences ^a	2022-18 ^b	2022-19 ^b	2022-20 ^b	2022-21 ^b
BA.1	175	491 224	0.11	0.21	0.20	0.02

^bRelative proportions in %

*BA.1.X and BA.2.X include all BA.1 and BA.2 pooled descendent lineages, except those already shown in the table above.

The blue rows indicate the dominant lineages. The grey rows indicate the lineages that are increasing in prevalence.

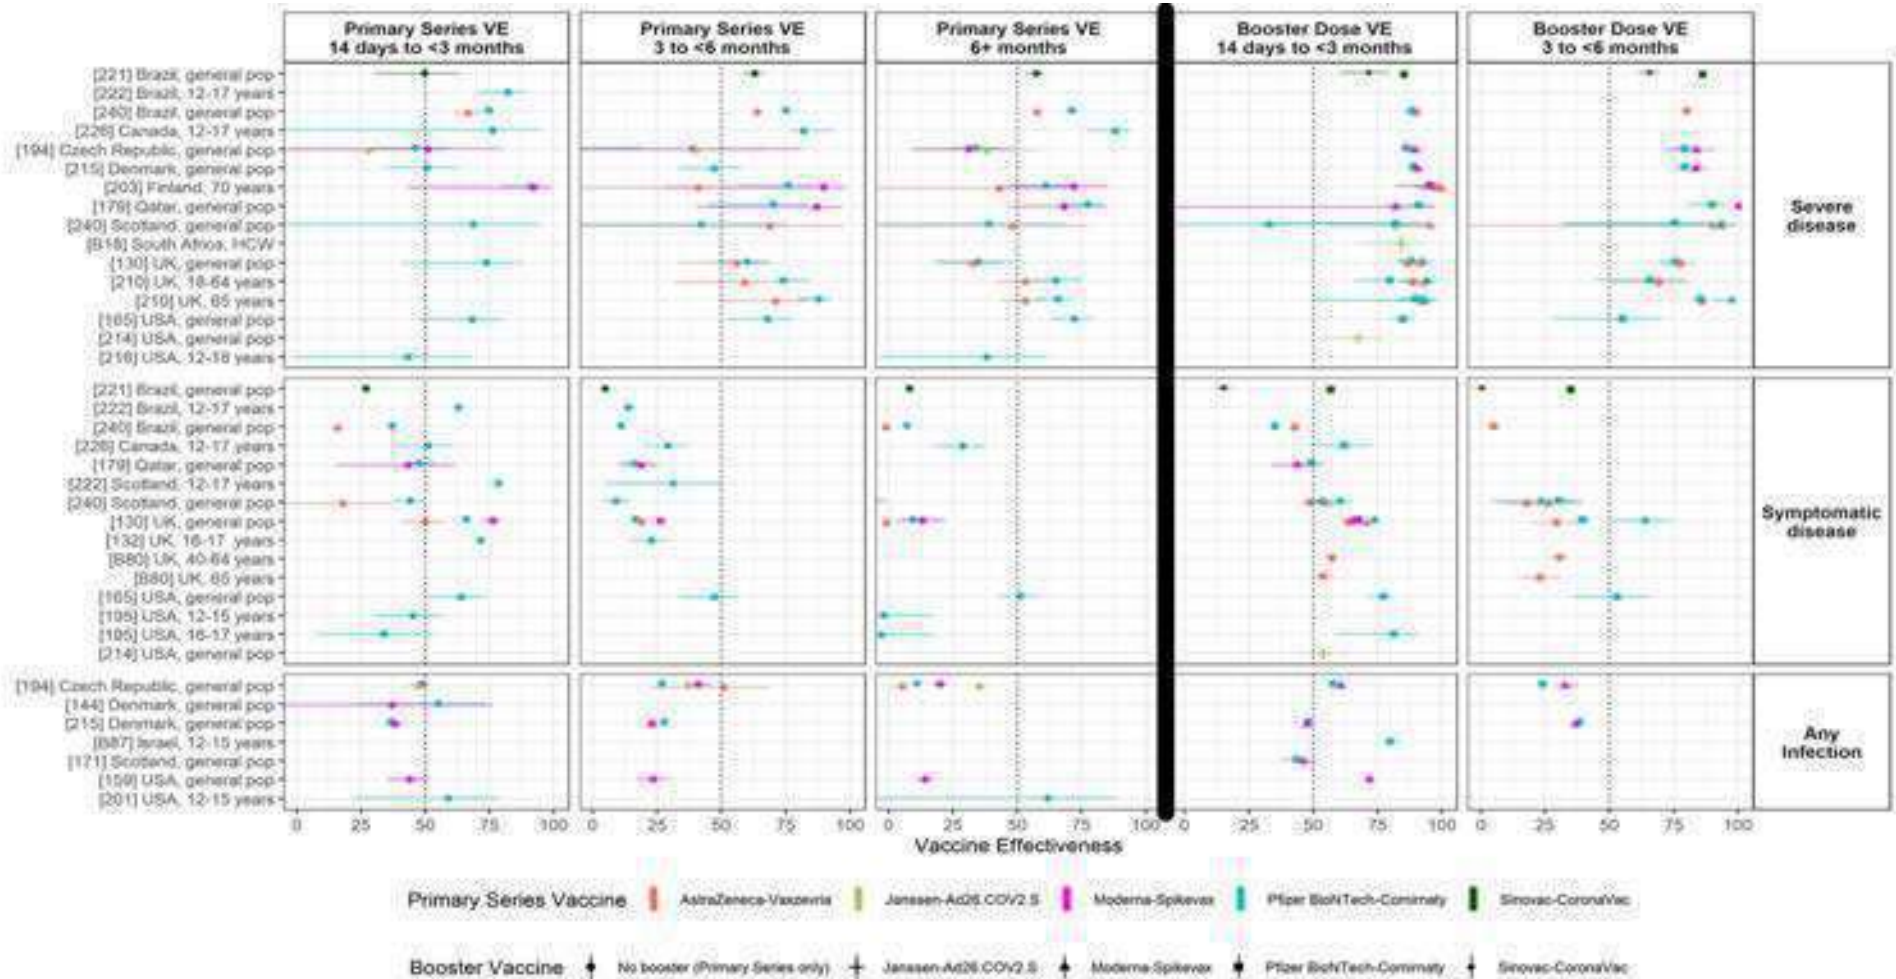

Characteristics of Omicron

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Table 3 summarizes the phenotypic characteristics of the Omicron VOC and its sublineages for which evidence is available since the [last update on 25 May 2022](#). Some of these studies have not been peer-reviewed and the findings must, therefore, be interpreted with due consideration of this limitation.

Table 3: Summary of phenotypic characteristics* of the Omicron VOC

Public health domain of impact	Omicron (B.1.1.529)	Omicron sublineages			
		BA.1	BA.2	BA.4	BA.5
Transmissibility	Growth advantage and increased transmissibility compared to Delta (Campbell 2021) ²	Lower transmissibility compared to BA.2 (Atkulwar 2022) ³	Increased transmissibility compared to BA.1 ³	No studies on relative transmissibility compared to BA.1 and BA.2	No studies on relative transmissibility compared to BA.1 and BA.2
Disease severity	Overall evidence suggests lower severity despite contrasting evidence. Earlier studies reported lower severity compared to Delta. ^{1,4–7} However, more recent studies reported similar ^{8,9} or increased severity ¹⁰ compared to Delta. ^{1,4–7,11 12}	No difference in disease severity compared to BA.2 ¹³	No difference in disease severity compared to BA.1 ¹³	Currently available evidence does not suggest a difference in disease severity compared to BA.1 ¹⁴	Currently available evidence does not suggest a difference in disease severity compared to BA.1 ^{14,15}
Risk of reinfection	Reduced risk of Omicron reinfection if previously infected with a different SARS-CoV-2 variant ^{16,17}	Reduced risk of reinfection with BA.1 following infection with BA.2 ¹⁸	Reduced risk of reinfection with BA.2 following infection with BA.1 ¹⁸	No specific data available	No specific data available
Impact on antibody responses	Reduction in neutralizing activity reported as compared to other VOCs ^{19–21}	Lower neutralising antibody titers compared to the index virus ²⁰	Lower neutralising antibody titers compared to the index virus ²⁰	Lower neutralising antibody titres (7.6-fold) compared to BA.1 ^{22–24}	Lower neutralising antibody titres (7.5-fold) compared to BA.1 ^{22,24}
Impacts on diagnostics	PCR assays that include multiple gene targets maintain their accuracy to detect Omicron ²⁵ ; S gene target failure/positivity (SGTF) may be a proxy for screening. Limited to no impact on sensitivity of Ag-RDTs observed ^{26–29}	S gene target failure.	The majority will be S gene target positive (SGTP).	S gene target failure.	S gene target failure.
Impact on treatment	No difference in the effectiveness of antiviral agents (polymerase and protease inhibitors) against the Omicron variant ³⁰ . Conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduced effectiveness of other monoclonal antibodies ^{31–34}	Reduced efficacy of casirivimab-imdevimab against BA.1 ³⁵	Reduced neutralising activity of sotrovimab ³⁵ , casirivimab and imdevimab against BA.2 ³⁶	Reduced neutralising activity of casirivimab and imdevimab ³⁶	Reduced neutralising activity of casirivimab and imdevimab ³⁶
Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant				

Figure 5. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

Abbreviations: pop=population; HCW=healthcare workers. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the summary table of VE effectiveness studies on view-hub.org (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes severe disease, hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, nine point estimates for the primary series with confidence intervals below 0 are not shown in the Omicron plot: two estimates from reference #144 against infection at 3 to <6 months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), two estimates from reference #179 against symptomatic disease at 6+ months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), and five estimates from reference #240 (one AstraZeneca-Vaxzevria estimate at 3 to <6 months; three AstraZeneca-Vaxzevria estimates and one Pfizer BioNTech estimate at 6+ months).

Figure 5 summarizes the impact of Omicron variant on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Additional information on vaccine performance against VOCs can also be found in Annex 4. Since the last [update](#), one new study (not yet peer-reviewed) assessing absolute vaccine effectiveness of three doses of Pfizer BioNTech-Comirnaty among children in Israel has been added to the figure.³⁵ The study found three doses of the vaccine to be 80% effective (95% CI: 76.7-83.1) at preventing Omicron infection among children 12-15 years of age within approximately two months of vaccination with the third dose.

Interpretation of the results of absolute VE for the Omicron variant

To date, 22 studies from 10 countries (Brazil, Canada, Czech Republic, Denmark, Finland, Israel, Qatar, South Africa, the United Kingdom and the United States of America) have assessed the duration of protection of five vaccines against the Omicron variant (six studies assessed VE of primary series vaccination only, four assessed VE of booster vaccination only, and 12 assessed both). Findings from these studies show reduced VE of COVID-19 primary series vaccines against the Omicron variant for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for the other VOCs. Importantly though, VE estimates against the Omicron variant remain higher for *severe disease*, in the majority of studies. Booster vaccination substantially improves VE for all outcomes and for all combinations of schedules with estimates available for both primary series and booster vaccination. VE declines more with time after booster vaccination for symptomatic disease and infection than it does for severe disease; however, studies that assess VE of booster vaccination beyond six months are needed to evaluate the longer duration of protection.

For *severe disease*, within the first three months of primary series vaccination, six of 12 (50%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty) were $\geq 70\%$. Of the two studies available for vector vaccines, one reported a VE of $<70\%$ for AstraZeneca-Vaxzevria, and the other reported a VE of $<50\%$ for Janssen-Ad26.COVS.2.S. One study available for inactivated vaccines (Sinovac-CoronaVac) reported a VE equal to 50%. Beyond three months after vaccination, 13 of 28 (46%) VE estimates for the mRNA vaccines were $\geq 70\%$ while 19 (68%) were $\geq 50\%$; one of the 12 (8%) VE estimates for AstraZeneca-Vaxzevria was $\geq 70\%$ while eight (67%) were $\geq 50\%$, but neither of the two estimates for Janssen-Ad26.COVS.2.S were $\geq 50\%$. The two available VE estimates beyond three months of vaccination for Sinovac-CoronaVac were $\geq 50\%$.

Booster vaccination improved VE against severe disease in all studies in which it was assessed. There were 33 estimates of an mRNA booster, two estimates a booster dose of Janssen-Ad26.COVS.2.S, and one estimates a booster dose of Sinovac-CoronaVac. Across the datasets, only one estimate for Pfizer BioNTech-Comirnaty as a booster dose and one for Janssen-Ad26.COVS.2.S as a booster dose below 70% between 14 days and three months of receipt of a booster dose. At three to six months post mRNA booster, 17 of 20 (85%) estimates showed VE $\geq 70\%$ (an mRNA vaccine was given as the primary series in 13 of the 20 estimates while AstraZeneca-Vaxzevria and Sinovac-CoronaVac were given as the primary series for six and one of the 20 estimates, respectively).

VE estimates against *symptomatic disease* and *infection* within the first three months of primary series vaccination tended to be lower than against severe disease, and VE decreased more substantially over time. For *symptomatic disease* within the first three months of primary series vaccination, three of 13 (23%) VE estimates for the mRNA vaccines were $\geq 70\%$ and seven (54%) were $\geq 50\%$; none of the three available VE estimates for AstraZeneca-Vaxzevria nor the single estimate for Sinovac-CoronaVac were above 50%. Beyond three months after vaccination, one of the 29 (3%) VE estimates were $\geq 50\%$ (21 estimates evaluated mRNA vaccines, six evaluated AstraZeneca-Vaxzevria, and two evaluated Sinovac-CoronaVac). Booster with an mRNA vaccination after completion of a primary series of an

mRNA vaccine, AstraZeneca-Vaxzevria, or Sinovac-CoronaVac, improved VE against *symptomatic disease* with four of 20 (20%) VE estimates $\geq 70\%$ and 15 (75%) estimates $\geq 50\%$ between 14 days and three months post booster. However, booster dose protection declined with time since vaccination with only two of twelve (17%) available estimates indicating a VE of $\geq 50\%$ at three to six months following receipt of an mRNA booster dose. Neither the single estimate for a booster dose of AstraZeneca-Vaxzevria nor the single estimate for a booster dose of Sinovac-CoronaVac three to six months post vaccination was above 50%. VE against *infection* showed a similar pattern as that against *symptomatic disease*.

WHO regional overviews:

Epidemiological week 30 May – 5 June 2022**

African Region

After reporting increasing trends for a month, the African Region has reported a decline in the number of new weekly cases for the third consecutive week, with over 26 000 new cases, a 29% decrease as compared to the previous week. However, eleven (22%) countries reported an increase in the number of new cases of over 20%, with the greatest proportional increases observed in Ghana (352 vs 73 new cases; +382%), Eritrea (10 vs three new cases; +233%) and Ethiopia (2483 vs 889 new cases; +179%). The highest numbers of new cases were reported from South Africa (14 885 new cases; 25.1 new cases per 100 000; -42%), Ethiopia (2483 new cases; 2.2 new cases per 100 000; +179%), and Réunion (2046 new cases; 228.5 new cases per 100 000; -37%).

The number of new weekly deaths in the Region decreased by 13% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from South Africa (171 new deaths; <1 new death per 100 000 population; -19%), Zimbabwe (10 new deaths; <1 new death per 100 000; +67%), and Réunion (seven new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [African Region](#)

Region of the Americas

Following an increasing trend since mid-April 2022, the Region of the Americas has reported a decrease in case incidence. Over 1.1 million new weekly cases were reported, a 1% decrease as compared to the previous week. However, sixteen (29%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Ecuador (7215 vs 2400 new cases; +201%), Haiti (74 vs 29 new cases; +155%) and Guyana (627 vs 347 new cases; +81%). The highest numbers of new cases were reported from the United States of America (657 268 new cases; 198.6 new cases per 100 000; -11%), Brazil (216 334 new cases; 101.8 new cases per 100 000; +36%), and Chile (55 211 new cases; 288.8 new cases per 100 000; +16%).

The number of new weekly deaths in the Region increased by 23% as compared to the previous week, with over 3300 new deaths reported. The highest numbers of new deaths were reported from the United States of America (1703 new deaths; <1 new death per 100 000; -33%), Brazil (652 new deaths; <1 new death per 100 000; -21%), and Canada (304 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported just under 21 000 new weekly cases, representing a 19% increase as compared to the previous week. Six (27%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Somalia (30 vs 14 new cases; +114%), Morocco (2188 vs 1202 new cases; +82%) and Bahrain (4806 vs 3187 new cases; +28%). The highest numbers of new cases were reported from Saudi Arabia (4545 new cases; 13.1 new cases per 100 000; +26%), Bahrain (4086 new cases; 240.1 new cases per 100 000; +28%), and the United Arab Emirates (3269 new cases; 33.1 new cases per 100 000; +26%).

The number of new weekly deaths in the Region decreased by 14% as compared to the previous week, with over 80 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (22 new deaths; <1 new death per 100 000; -37%), Egypt (14 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Saudi Arabia (12 new deaths; <1 new death per 100 000; -20%).

Updates from the [Eastern Mediterranean Region](#)

European Region

In the European Region, the number of new cases has continued to decline since mid-March 2022, with over 744 000 new weekly cases, an 18% decrease as compared to the previous week. Six (10%) countries in the Region reported increases in new cases of 20% or greater: Monaco (132 vs 59 new cases; +124%), Uzbekistan (113 vs 81 new cases; +40%) and Luxembourg (1559 vs 1181 new cases; +32%). The highest numbers of new cases were reported from Germany (215 955 new cases; 259.7 new cases per 100 000; +16%), France (128 198 new cases; 197.1 new cases per 100 000; +13%), and Portugal (120 711 new cases; 1172.4 new cases per 100 000; -31%).

Over 2000 new weekly deaths were reported, a 35% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (565 new deaths; <1 new death per 100 000; -7%), Italy (380 new deaths; <1 new death per 100 000; -39%), and France (272 new deaths; <1 new death per 100 000; -7%).

Updates from the [European Region](#)

South-East Asia Region

After a decreasing trend in the number of new weekly cases observed since mid-January 2022, the South-East Asia Region reported over 50 000 new cases this week, representing a 1% increase as compared to the previous week. Three (30%) countries showed increases in the number of new cases of 20% or greater: India (23 774 vs 16 672 new cases; +43%), Indonesia (2385 vs 1825 new cases; +31%), and Nepal (72 vs 59 new cases; +22%). The highest numbers of new cases were reported from Thailand (24 145 new cases; 34.6 new cases per 100 000; -23%), India (23 774 new cases; 1.7 new cases per 100 000; +42), and Indonesia (2385 new cases; <1 new case per 100 000; +31%).

The Region reported 350 deaths, a decrease of 23% as compared to the previous week. The highest numbers of new deaths were reported from Thailand (199 new deaths; <1 new death per 100 000; -12%), India (106 new deaths; <1 new death per 100 000; -39%), and Indonesia (41 new deaths; <1 new death per 100 000; -21%).

Reports of an outbreak of COVID-19 reported in the Democratic People's Republic of Korea continue through official media on 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Updates from the [South-East Asia Region](#)

Western Pacific Region

With over one million new weekly cases reported, the Western Pacific Region shows a decreasing trend for the second consecutive week (-19% as compared to the previous week). Six (18%) countries reported increases in new cases of 20% or greater, with the largest proportional increases observed in Papua New Guinea (205 vs 31 new cases; +561%), Vanuatu (1174 vs 205 new cases; +473%) and Tonga (254 vs 94 new cases; +170%). The highest numbers of new cases were reported from China (528 432 new cases; 35.9 new cases per 100 000; -8%), Australia (221 935 new cases; 870.3 new cases per 100 000; -25%), and Japan (122 241 new cases; 96.7 new cases per 100 000; -40%).

The Region reported over 1600 new weekly deaths, representing a 7% increase as compared to the previous week. The highest numbers of new deaths were reported from China (910 new deaths; <1 new death per 100 000; +57%), Australia (288 new deaths; <1 new death per 100 000; -17%), and Japan (199 new deaths; <1 new death per 100 000; -18%).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Monthly Operational Update

The [Monthly operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this edition, highlights of country-level actions and WHO support to countries include:

- WHO, Government of Japan, and Governments of the Marshall Islands, Federated States of Micronesia and Palau partner to enhance COVID-19 preparedness and response
- WHO/Europe mission to Tajikistan to support the Ministry of Health and Social Protection of the Population of the Republic of Tajikistan with clinical management of COVID-19
- Expansion of South Sudan's COVID-19 vaccination to remote regions
- Eastern Mediterranean Region publishes its COVID-19 Strategic Preparedness and Response Plan for 2022
- Region of the Americas establishes a high-level commission on mental health and COVID-19
- Integrating SARS-CoV-2 into influenza sentinel surveillance- field experience in Togo
- Engaging with Parliamentarians in Nepal to strengthen Risk Communications and Community Engagement (RCCE)
- Technical and targeted multi-sectoral support to manage COVID-19 waste in the African Region
- Shipment of rapid antigen tests to Iraq
- Nigeria holds first national Training of Trainers (ToT) workshop on infodemic management
- COVID-19 Vaccine Delivery Partnership supports countries to scale-up vaccination strategies
- WHO plays advisory role to International Olympic Committee for Beijing 2022 Winter Olympic and Paralympic Games
- Act-A Health Systems Response Connector (HSRC) supports Member States to translate COVID-19 tools into national interventions
- Progress update on the utilization of OpenWHO training platform

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] Since 21 May, data for COVID-19 cases and deaths in Northern Ireland was no longer included in the United Kingdom updates (see [here](#) for the official announcement).

Annex 2. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than four months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase three RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase three RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase three estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected $>$ seven days and $<$ six months after complete vaccination and that use an ancestral strain as the reference are included in Table 3.

Annex 3. Methods for Figure 5

- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when Omicron was the predominant circulating variant. Only studies providing VE estimates of individual vaccines are included in the plot (studies assessing combined VE of more than one vaccine are excluded). In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.
- For the primary series VE, estimates are only included in the plot for studies that report absolute VE for more than one time period for an individual vaccine. Thirteen studies of VE against Omicron provided only a single cumulative VE estimate for an individual vaccine, which due to varying lengths of time since vaccination are difficult to interpret due to the marked waning of VE over time with Omicron.

Annex 4. Summary of Primary Series Vaccine Performance against Variants of Concern (VE data as of 28 May 2022; Neutralization data as of 2 June 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺									Vaccines without WHO EUL ⁺	
	AstraZeneca- Vaxzevria/ SII - Covishield	Beijing CNBG- BBIBP-CorV	Bharat-Covaxin	Cansino - Convidecia	Janssen- Ad26.COV 2.S	Moderna- mRNA-1273	Novavax- Nuvaxovid/ SII - Covavax	Pfizer BioNTech- Comirnaty	Sinovac- CoronaVac	Anhui ZL- Recombinant	Gamaleya- Sputnik V
Alpha, Beta, Gamma											
Summary of VE*	see update from 11 January 2022 for details of vaccine performance against Alpha, Beta, and Gamma variants of concern										
Delta											
Summary of VE*	see update from 27 April 2022 for details of vaccine performance against Delta variant of concern										
Omicron ³⁸											
Summary of VE*	Reduced protection against infection and symptomatic disease; possible reduced protection against for severe disease but limited evidence										
- Severe disease	-	-	-	-	-	↓to↓↓/↓↓↓↓ ₂	-	↓↓to↓↓↓↓ ₅	-	-	-
- Symptomatic disease	↓↓↓↓ ₁	-	-	-	-	↓↓/↓↓↓↓ ₂	-	↓↓↓↓ ₃	-	-	-
- Infection	↓↓↓↓ ₁	-	-	-	-	↓↓↓↓ ₃	-	↓↓↓↓ ₃	-	-	-
Neutralization	↓↓↓↓ ₇	↓to↓↓↓↓ ₄	↓↓↓ ₁	-	↓to↓↓↓↓ ₄	↓↓↓↓ ₁₈	-	↓↓↓↓ ₄₆	↓↓to↓↓↓↓ ₅	-	↓↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

COVID-19 Weekly Epidemiological Update

Edition 94, published 1 June 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 29 May 2022

Globally, the number of new weekly cases has continued to decline since a peak in January 2022. During the week of 23 until 29 May 2022, over 3.3 million cases were reported, an 11% decrease as compared to the previous week (figure 1). The number of new weekly deaths also continues to decline, with over 9 600 fatalities reported, representing a 3% decrease as compared to the previous week.

At the regional level, the number of new weekly cases increased in the American Region (+9%) and in the Eastern Mediterranean Region (+1%), while it decreased in the remaining four WHO regions.

The number of new weekly deaths increased in the Western Pacific Region (+18%), in the African Region (+15%), and in the Region of the Americas (+13%), while decreasing trends were observed in the remaining three regions.

As of 29 May 2022, over 526 million confirmed cases and over six million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 29 May 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the United States of America (736 298 new cases; +3%), China (576 367 new cases; +6%), Australia (294 128 new cases; -18%), Japan (203 365 new cases; -18%), and Germany (183 844 new cases; -38%).

The highest number of new weekly deaths were reported from the United States of America (2 461 new deaths; +25%), Brazil (826 new deaths; +16%), Italy (624 new deaths; -15%), the Russian Federation (605 new deaths; -11%), and China (578 new deaths; +82%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 29 May 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Western Pacific	1 299 894 (38%)	-10%	59 958 154 (11%)	1 506 (16%)	18%	230 479 (4%)
Americas	1 139 104 (34%)	9%	157 027 750 (30%)	4 229 (44%)	13%	2 742 377 (44%)
Europe	842 866 (25%)	-30%	220 678 128 (42%)	3 117 (32%)	-22%	2 012 067 (32%)
South-East Asia	50 204 (1%)	-8%	58 122 050 (11%)	457 (5%)	-15%	788 614 (13%)
Africa	34 126 (1%)	-36%	8 988 466 (2%)	242 (3%)	15%	171 434 (3%)
Eastern Mediterranean	17 580 (1%)	1%	21 769 191 (4%)	96 (1%)	-45%	342 813 (5%)
Global	3 383 774 (100%)	-11%	526 544 503 (100%)	9 647 (100%)	-3%	6 287 797 (100%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

There continues to be a decline in the number of SARS-CoV-2 sequences submitted to GISAID, with 152 476 submitted within the last 30 days. The Omicron VOC remains the dominant variant circulating globally, accounting for nearly all sequences reported. Among the Omicron sublineages, BA.2 is the dominant sublineage, despite declining from 78% to 75% of Omicron sequences submitted in the last 30 days. The BA.1 sublineage has also declined in prevalence from 7% to 4%. Three Omicron sublineages have shown an increasing trend among Omicron sequences submitted in the last 30 days: BA.2.12.1 has risen from 11% to 16%; BA.4 has risen from 2% to 3%; and BA.5 has risen from 1% to 2%. During the same period, the prevalence of BA.3 has declined to <1%.

These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as changes in sampling and sequencing strategies in multiple countries.

WHO regional overviews:

Epidemiological week 23-29 May 2022**

African Region

After reporting increasing trends for a month, the African Region reported a decline in the number of new weekly cases for the second consecutive week, with over 34 000 new cases, a 36% decrease as compared to the previous week. However, eleven (22%) countries reported an increase in the number of new cases of over 20%, with the greatest proportional increases observed in Angola (234 vs 46 new cases; +409% and included batch reporting), Kenya (464 vs 211 new cases; +120%) and Ethiopia (889 vs 406 new cases; +119%). The highest numbers of new cases were reported from South Africa (25 541 new cases; 43.1 new cases per 100 000 population; -35%), Réunion (3252 new cases; 363.2 new cases per 100 000; -40%), and Ethiopia (889 new cases; <1 new case per 100 000; a +119%).

The number of new weekly deaths increased by 15% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from South Africa (211 new deaths; <1 new death per 100 000 population; +19%), Réunion (seven new deaths; <1 new death per 100 000; -13%), and Zimbabwe (six new deaths; <1 new deaths per 100 000; -50%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has continued to report an increasing trend in case incidence since mid-April 2022, with over 1.1 million new weekly cases, a 9% increase as compared to the previous week. Ten (18%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Saba (18 vs 4 new cases; +350%), Dominican Republic (1909 vs 838 new cases; +128%) and Brazil (158 732 vs 97 674 new cases; +63%). The highest number of new cases were reported from the United States of America (736 298 new cases; 222.4 new cases per 100 000; +3%), Brazil (158 732 new cases; 74.7 new cases per 100 000; +63%), and Argentina (51 778 new cases; 114.6 new cases per 100 000; +19%).

The number of new weekly deaths in the Region increased by 13% as compared to the previous week, with over 4200 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2461 new deaths; <1 new death per 100 000; +25%), Brazil (826 new deaths; <1 new death per 100 000; +16%), and Canada (303 new deaths; <1 new death per 100 000; -32%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 17 000 new weekly cases, representing a 1% increase as compared to the previous week. Seven (32%) countries reported increases in the number of new cases of 20% or greater, with the greatest proportional increases observed in Kuwait (751 vs 105 new cases; +615% and included batch reporting), Sudan (92 vs 34 new cases; +171%) and Morocco (1202 vs 824 new cases; +46%). The highest numbers of new cases were reported from Saudi Arabia (3621 new cases; 10.4 new cases per 100 000; -4%), Bahrain (3187 new cases; 187.3 new cases per 100 000; -16%), and the United Arab Emirates (2603 new cases; 26.3 new cases per 100 000; +13%).

The number of new weekly deaths in the Region decreased by 45% as compared to the previous week, with 96 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (35 new deaths; <1 new death per 100 000; -36%), Saudi Arabia (15 new deaths; <1 new death per 100 000; +7%), and Egypt (14 new deaths; <1 new death per 100 000; -33%).

Updates from the [Eastern Mediterranean Region](#)

European Region

In the European Region, the number of new cases has continued to decline since mid-March 2022, with over 842 000 new weekly cases, a 30% decrease as compared to the previous week. Three (5%) countries in the Region reported increases in new cases of 20% or greater: Armenia (25 vs 18 new cases; +39%), Denmark (4426 vs 3269 new cases; +35%) and Azerbaijan (49 vs 40 new cases; +23%). The highest numbers of new cases were reported from Germany (183 844 new cases; 221.1 new cases per 100 000; -38%), Portugal (176 910 new cases; 1718.3 new cases per 100 000; -8%), and Italy (144 478 new cases; 242.2 new cases per 100 000; -27%).

Over 3100 new weekly deaths were reported, a 22% decrease as compared to the previous week. The highest numbers of new deaths were reported from Italy (624 new deaths; 1.0 new death per 100 000; -15%), the Russian Federation (605 new deaths; <1 new death per 100 000; -11%), and the United Kingdom (314 new deaths; <1 new death per 100 000; -43%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region has continued to report decreasing trends in the incidence of weekly cases and deaths since mid-January 2022, with over 50 000 new cases and over 400 new deaths reported this week, decreases of 8% and 15% respectively as compared to the previous week. Two countries showed increases in the number of new cases of 20% or greater: Bhutan (40 vs 4 new cases; +900% but due to batch reporting) and Timor-Leste (17 vs 6 new cases; +183%). The highest numbers of new cases were reported from Thailand (31 154 new cases; 44.6 new cases per 100 000; -17%), India (16 672 new cases; 1.2 new cases per 100 000; +13%), and Indonesia (1825 new cases; <1 new case per 100 000; similar to the previous week's figures).

The highest numbers of new deaths in the Region were reported from Thailand (226 new deaths; <1 new death per 100 000; -18%), India (173 new deaths; <1 new death per 100 000; -13%), and Indonesia (52 new deaths; <1 new death per 100 000; -19%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

After an increasing trend in the number of new weekly cases observed during the last three weeks, the Western Pacific Region reported just under 1.3 million new cases this week, a 10% decrease as compared to the previous week. Two countries reported increases in new cases of 20% or greater: Northern Mariana Islands (Commonwealth of the) (18 vs 10 new cases; +80%) and French Polynesia (53 vs 37 new cases; +43%). The highest numbers of new cases were reported from China (576 367 new cases; 39.2 new cases per 100 000; +6%), Australia (294 128 new cases; 1153.4 new cases per 100 000; -18%), and Japan (203 365 new cases; 160.8 new cases per 100 000; -18%).

The Region reported over 1500 new weekly deaths, representing an 18% increase as compared to the previous week. The highest numbers of new deaths were reported from China (578 new deaths; <1 new death per 100 000; +82%), Australia (347 new deaths; 1.4 new deaths per 100 000; +13%), and Japan (244 new deaths; <1 new death per 100 000; -4%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 93, published 25 May 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 22 May 2022

Globally, the number of new weekly cases has continued the declining trend observed since a peak in January 2022. During the week of 16 through 22 May 2022, over 3.7 million cases were reported, a 3% decrease as compared to the previous week (figure 1). The number of new weekly deaths also continues to decline, with over 9000 fatalities reported, representing an 11% decrease as compared to the previous week.

At the regional level, the number of new weekly cases increased in the Region of the Americas (+13%) and in the Western Pacific Region (+6%), while decreasing trends were observed in the remaining four regions. The number of new weekly deaths increased in the Eastern Mediterranean Region (+30%), remained stable in the Western Pacific and the Region of the Americas (both <1%), and decreased in the other three regions.

As of 22 May 2022, over 522 million confirmed cases and over six million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 22 May 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the United States of America (713 882 new cases; +18%), China (543 290 new cases; +39%), Australia (360 323 new cases; +8%), Germany (268 396 new cases; -35%), and Japan (249 210 new cases; -11%).

The highest number of new weekly deaths were reported from the United States of America (1 957 new deaths; +2%), Italy (736 new deaths; -4%), Brazil (713 new deaths; +3%), the Russian Federation (680 new deaths; -6%), and Spain (564 new deaths; +118%).

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

The total number of SARS-CoV-2 sequences submitted to GISAID continues to show a declining trend (Figure 4). The Omicron VOC is the dominant variant circulating globally, accounting for nearly all sequences reported to GISAID within the last 30 days. Among Omicron lineages, BA.2 and its descendent lineages (pooled lineages named BA.2.X) are the dominant variants. As of the epidemiological week 18 in 2022 (1-7 May), the relative proportions of BA.2.X, BA.4, and BA.5 were 94%, 0.8%, and 1%, respectively. Among BA.2 descendent lineages, BA.2.12.1 accounted for 17% (Figure 5). Delta and other VOCs (Alpha, Beta and Gamma) have declined significantly over time but may still be circulating below detection levels.

Studies are ongoing to further elucidate the characteristics of Omicron lineages that appear to show a growth advantage as compared to BA.1 and BA.2. Further, additional evidence is anticipated regarding the severity or clinical manifestations for Omicron lineages which have a mutation at the spike locus S:L452. With currently available data, BA.4, BA.5 and BA.2.12.1 appear to be spreading faster in countries with substantial prior waves of cases due to BA.1; while countries that experienced more substantial BA.2 waves appear to have fewer cases due to BA.4, BA.5 and BA.2.12.1 at this stage. The extent of vaccination in each country, also likely influences the impact of these emerging Omicron descendent lineages.

All Omicron descendant lineages continue to be tracked under the umbrella of Omicron VOC, given the lack of evidence on changes that would indicate difference in phenotype, such as associated severity.

Figure 4. The number of Omicron sequences by sister-lineage*, as of 23 May 2022

*Omicron sister-lineages include Omicron lineages BA.1 and pooled descendent lineages named BA.1.X, BA.2 and all pooled descendent lineages named BA.2.X, BA.3, BA.4 and BA.5. Source: SARS-CoV-2 sequence data and metadata from GISAID, extracted from GISAID on 23 May 2022 at 10 CET.

Figure 5. The number of Omicron sequences by Omicron sister-lineages* and BA.2 descendent lineages, as of 23 May 2022

*Omicron descendent lineages with past and present signs of growth advantage are shown in this figure. BA.1.X and BA.2.X show pooled descendent lineages of BA.1 and BA.2 excluding those that have been reported here. Source: SARS-CoV-2 sequence data and metadata from GISAID, extracted from GISAID on 23 May 2022 at 10 CET.

Characteristics of Omicron

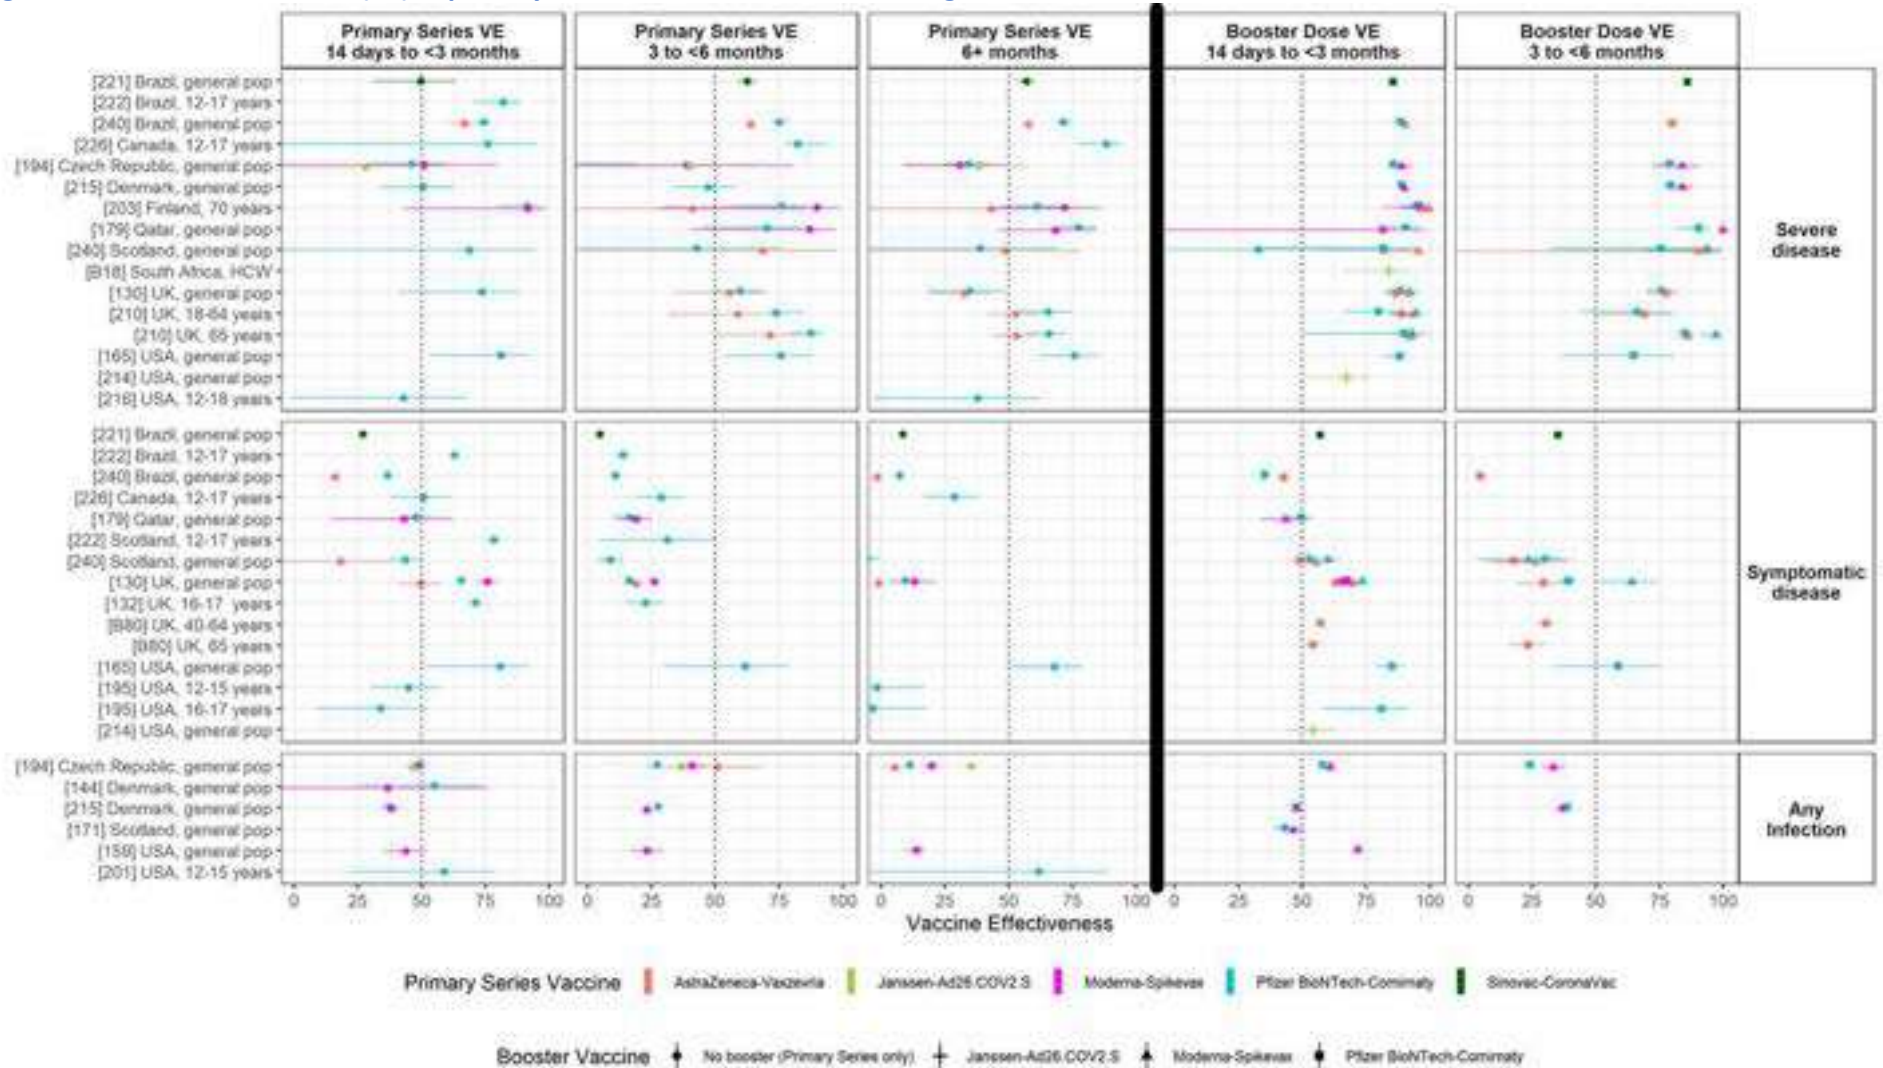

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Table 2 summarizes the phenotypic characteristics of the Omicron VOC and its sublineages for which evidence is available since the [last update on 11 May 2022](#). Some of these studies have not been peer-reviewed and the findings must, therefore, be interpreted with due consideration of this limitation.

Table 2: Summary of phenotypic characteristics* of the Omicron VOC

Public health domain of impact	Omicron (BA.1.1.529)	Omicron sublineages	
		BA.1	BA.2
Transmissibility	<ul style="list-style-type: none"> Growth advantage and increased transmissibility compared to Delta (Campbell 2021)¹ 	Lower transmissibility compared to BA.2 ²	Increased transmissibility compared to BA.1 ²
Disease severity	<ul style="list-style-type: none"> Overall evidence suggests lower severity despite contrasting evidence. Earlier studies reported lower severity compared to Delta³⁻⁷. However, more recent studies reported similar^{8,9} or increased severity compared to Delta.^{3-5,7,10,11} 	No difference in disease severity compared to BA.2 ⁷	No difference in disease severity compared to BA.1 ⁷
Risk of reinfection	<ul style="list-style-type: none"> Reduced risk of Omicron reinfection if previously infected with a different SARS-CoV-2 variant^{12,13} 	Reduced risk of reinfection with BA.1 following infection with BA.2 ¹⁴	Reduced risk of reinfection with BA.2 following infection with BA.1 ¹⁴
Impact on antibody responses	Reduction in neutralizing activity reported as compared to other VOCs ¹⁵⁻¹⁷	<ul style="list-style-type: none"> Lower neutralising antibody titers compared to the Index virus^{16,17} Possible reduced vaccine-induced and infection-induced neutralisation and non-neutralisation activity compared to BA.2^{15,17,18} 	<ul style="list-style-type: none"> Lower neutralising antibody titers compared to the Index virus^{16,17} Possible increased vaccine-induced and infection-induced neutralization and non-neutralisation activity compared to BA.1 (Yu 2022, Bartsch 2022)^{15,17,18}
Impacts on diagnostics	PCR assays that include multiple gene targets maintain their accuracy to detect Omicron; S gene target failure/positivity (SGTF) may be a proxy for screening. Limited to no impact on sensitivity of Ag-RDTs observed ¹⁷⁻²¹	No specific data available. No S gene target failure. ¹⁹⁻²²	No specific data available. The majority will be S gene target positive (SGTF). ¹⁹⁻²²
Impact on treatment	<ul style="list-style-type: none"> No difference in the effectiveness of antiviral agents (polymerase and protease inhibitors) against the Omicron variant²⁴ Conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduced effectiveness of other monoclonal antibodies²⁵⁻²⁸ 	Reduced efficacy of casirivimab-imdevimab against BA.1 ²⁹	Reduced neutralizing activity of sotrovimab against BA.2 ²⁹
Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant		

*Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision

Figure 6. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

* Abbreviations: pop=population; HCW=healthcare workers. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the [summary table](#) of VE effectiveness studies on [view-hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes severe disease, hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, nine point estimates for the primary series with confidence intervals below 0 are not shown in the Omicron plot: two estimates from reference #144 against infection at 3 to <6 months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), two estimates from reference #179 against symptomatic disease at 6+ months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), and five estimates from reference #240 (one AstraZeneca-Vaxzevria estimate at 3 to <6 months; three AstraZeneca-Vaxzevria estimates and one Pfizer BioNTech estimate at 6+ months).

Figure 6 summarizes the impact of Omicron variant on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Additional information on vaccine performance against VOCs can also be found in Annex 4. Since the last [update](#), no new studies assessing absolute vaccine effectiveness have been added to the figures. Two studies that assessed relative vaccine effectiveness of a booster dose only (comparing persons receiving three doses to persons receiving two doses) were removed from the figure. As the interpretation of relative vaccine effectiveness is not comparable to absolute vaccine effectiveness (using unvaccinated persons as the comparison group), only estimates of absolute vaccine effectiveness are included in the figure.

Interpretation of the results of the VE for the Omicron variant

To date, 21 studies from nine countries (Brazil, Canada, Czech Republic, Denmark, Finland, Qatar, South Africa, the United Kingdom and the United States of America) have assessed the duration of protection of five vaccines against the Omicron variant (six studies assessed VE of primary series vaccination only, four assessed VE of booster vaccination only, and 11 assessed both). Findings from these studies show reduced VE of COVID-19 primary series vaccines against the Omicron variant for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for other four VOCs. Importantly though, VE estimates against the Omicron variant remain higher for *severe disease* in the majority of studies. Booster vaccination substantially improves VE for all outcomes and for all combinations of schedules with estimates available for both primary series and booster vaccination. VE declines more with time after booster vaccination for symptomatic disease and infection than it does for severe disease; however, studies that assess VE of booster vaccination beyond six months are needed to evaluate the longer duration of protection.

For *severe disease*, within the first three months of primary series vaccination, seven of 12 (58%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty) were $\geq 70\%$. Of the two studies available for vectored vaccines, one reported a VE of $<70\%$ for AstraZeneca-Vaxzevria, and the other reported a VE of $<50\%$ for Janssen-Ad26.COVS.2.S. One study available for inactivated vaccines (Sinovac-CoronaVac) reported a VE of 50%. Beyond three months after vaccination, 12 of 27 (44%) VE estimates for the mRNA vaccines were $\geq 70\%$, while 18 (77%) were $\geq 50\%$, one of the 12 (8%) VE estimates for AstraZeneca-Vaxzevria was $\geq 70\%$ while eight (67%) were $\geq 50\%$, and the two (100%) available VE estimates for Sinovac-CoronaVac were $\geq 50\%$; both estimates for Janssen-Ad26.COVS.2.S beyond three months of vaccination were $<50\%$.

Booster vaccination improved VE against *severe disease* in all studies in which it was assessed. There were 33 estimates of an mRNA booster, two estimates a booster dose of Janssen-Ad26.COVS.2.S, and one estimates a booster dose of Sinovac-CoronaVac. Across the datasets, only one estimate for Pfizer BioNTech-Comirnaty as a booster dose and one for Janssen-Ad26.COVS.2.S as a booster dose below 70% between 14 days and three months of receipt of a booster dose. At three to six months post mRNA booster, 18 of 20 (90%) estimates showed VE $\geq 70\%$ (an mRNA vaccine was given as the primary series in 13 of the 20 estimates, while AstraZeneca-Vaxzevria and Sinovac-CoronaVac were given as the primary series for six and one of the twenty estimates, respectively).

VE estimates against *symptomatic disease* and *infection* within the first three months of primary series vaccination tended to be lower than against severe disease, and VE decreased more substantially over time. For *symptomatic disease* within the first three months of primary series vaccination, only three of 13 (23%) VE estimates for the mRNA vaccines were $\geq 70\%$ and seven (54%) were $\geq 50\%$; all three (100%) VE estimates for AstraZeneca-Vaxzevria and the

single estimate for Sinovac (CoronaVac) were below 50%. Beyond three months after vaccination, none of the 28 VE estimates were $\geq 50\%$ (20 estimates evaluated mRNA vaccines, six evaluated AstraZeneca-Vaxzevria, and two evaluated Sinovac-CoronaVac). A booster with mRNA vaccine after completion of a primary series of an mRNA vaccine, AstraZeneca-Vaxzevria, or Sinovac-CoronaVac, improved VE against *symptomatic disease* with four of 19 (21%) VE estimates $\geq 70\%$ and 14 (74%) estimates $\geq 50\%$ between 14 days and three months post booster. However, booster dose protection declined with time since vaccination, with only two of twelve (17%) available estimates indicating a VE of $\geq 50\%$ at three to six months following receipt of an mRNA booster dose. Estimates for a booster dose of AstraZeneca-Vaxzevria (one estimate) and Sinovac-CoronaVac (one estimate) three to six months post vaccination indicated VE of $< 50\%$. VE against *infection* showed a similar pattern as that against *symptomatic disease*.

WHO regional overviews:

Epidemiological week 16-22 May 2022**

African Region

After a month of increasing trends, the African Region reported a decline both in the number of new weekly cases (over 49 000; -24%) and new weekly deaths (n=208; -22%) as compared to the previous week. However, 13 (27%) countries in the Region reported an increase in cases of over 20%, with some of the greatest proportional increases observed in Côte d'Ivoire (65 vs 22 new cases; +195%), Ethiopia (406 vs 207 new cases; +96%) and Burundi (509 vs 268 new cases; +90%). The highest numbers of new cases were reported from South Africa (39 203 new cases; 66.1 new cases per 100 000 population; -24%), Réunion (5383 new cases; 601.2 new cases per 100 000; -32%), and Zimbabwe (1436 new cases; 9.7 new cases per 100 000; +53%).

The highest numbers of new deaths in the Region were reported from South Africa (178 new deaths; <1 new death per 100 000 population; -25%), Zimbabwe (12 new deaths; <1 new death per 100 000; +33%), and Réunion (eight new deaths; <1 new deaths per 100 000; +33%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has continued to report an increasing trend since mid-April 2022, with over one million new weekly cases reported, a 13% increase as compared to the previous week. Twenty-four (43%) countries in the Region reported increases in new cases of 20% or greater, with the greatest proportional increases observed in Antigua and Barbuda (221 vs 58 new cases; +281%), Bolivia (Plurinational State of) (1193 vs 465 new cases; +157%) and Colombia (3795 vs 1671 new cases; +127%). The highest numbers of new cases were reported from the United States of America (713 882 new cases; 215.7 new cases per 100 000; +18%), Brazil (97 674 new cases; 46.0 new cases per 100 000; -19%), and Argentina (43 487 new cases; 96.2 new cases per 100 000; +28%).

The number of new weekly deaths in the Region remained stable as compared to the previous week (<1% increase), with over 3600 new deaths reported. The highest numbers of new deaths were reported from the United States of America (1957 new deaths; <1 new death per 100 000; +2%), Brazil (713 new deaths; <1 new death per 100 000; +3%), and Canada (411 new deaths; 1.1 new deaths per 100 000; -18%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

After the increasing trend observed during the past week (following a declining trend observed since mid-February 2022), the Eastern Mediterranean Region reported over 17 000 new weekly cases, representing a 12% decrease as compared to the previous week. Four (19%) countries in the Region reported increases in new cases of 20% or greater, with the greatest proportional increases observed in Jordan (305 vs 84 new cases; +263%), Morocco (824 vs 500 new cases; +65%) and Afghanistan (431 vs 320 new cases; +35%). The highest numbers of new cases were reported from Bahrain (3800 new cases; 223.3 new cases per 100 000; -23%), Saudi Arabia (3780 new cases; 10.9 new cases per 100 000; +2%), and the United Arab Emirates (2305 new cases; 23.3 new cases per 100 000; +8%).

The number of new weekly deaths in the Region increased by 30% when compared to the previous week, with over 150 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (55 new deaths; <1 new death per 100 000; +8%), Tunisia (53 new deaths; <1 new deaths per 100 000; +489%), and Egypt (21 new deaths; <1 new death per 100 000; -25%). All 53 deaths reported from Tunisia last week were batch reported on 18 May 2022.

Updates from the [Eastern Mediterranean Region](#)

European Region

In the European region, cases have continued to decline since mid--March 2022, with over 1.1 million new weekly cases, a 20% decrease as compared to the previous week. Three (5%) countries in the Region reported increases in new cases of 20% or greater: Spain (110 951 vs 51 716 new cases; +115%), Uzbekistan (127 vs 87 new cases; +46%) and Monaco (105 vs 15 new cases; +33%). The highest numbers of new cases were reported from Germany (268 396 new cases; 322.7 new cases per 100 000; -35%), Italy (199 116 new cases; 333.9 new cases per 100 000; -24%), and Portugal (164 225 new cases; 1595.1 new cases per 100 000; +7%).

The Region reported over 3500 new deaths, a 23% decrease as compared to the previous week. The highest numbers of new deaths were reported from Italy (736 new deaths; 1.2 new deaths per 100 000; -4%), the Russian Federation (680 new deaths; <1 new death per 100 000; -6%), and Spain (564 new deaths; 1.2 new deaths per 100 000; +118%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region has continued the decreasing trends observed since mid-January 2022, with over 54 000 new cases and over 500 new deaths reported, decreases of 23% and 12% respectively as compared to the previous week. Three (30%) countries in the Region showed increases in new cases of 20% or greater, with the largest proportional increases observed in the Maldives (93 vs 67 new cases; +39%) and Nepal (70 vs 56 new cases; +25%). The highest numbers of new cases were reported from Thailand (37 648 new cases; 53.9 new cases per 100 000; -23%), India (14 772 new cases; 1.1 new cases per 100 000; -24%), and Indonesia (1814 new cases; <1 new case per 100 000; -23%).

The highest numbers of new deaths in the Region were reported from Thailand (274 new deaths; <1 new death per 100 000; -29%), India (199 new deaths; <1 new deaths per 100 000; +33%), and Indonesia (64 new deaths; <1 new deaths per 100 000; -17%).

Reports of an outbreak of COVID-19 first reported in the Democratic People's Republic of Korea continue through official media on 12 May 2022; however, at present, no confirmed cases or deaths have been reported to WHO.

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region has shown an increasing trend in new weekly cases in the last three weeks, with over 1.4 million new cases, a 6% increase as compared to the previous week. Eight (25%) countries in the Region reported increases in new cases of 20% or greater, with the greatest proportional increases observed in Guam (238 vs 36 new cases; +562%), Fiji (116 vs 26 new cases; +346%) and Tonga (444 vs 246 new cases; +80%). The highest numbers of new cases were reported from China (543 290 new cases; 36.9 new cases per 100 000; +39%), Australia (360 323 new cases; 1413.0 new cases per 100 000; +8%), and Japan (249 210 new cases; 197.0 new cases per 100 000; -11%).

With over 1200 new deaths reported, the Region shows a stable trend (<1% increase) in new weekly deaths as compared to the previous week. The highest numbers of new deaths were reported from China (317 new deaths; <1 new death per 100 000; +64%), Australia (306 new deaths; 1.2 new deaths per 100 000; +15%), and the Republic of Korea (256 new deaths; <1 new death per 100 000; -27%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 2. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for

AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., >90%).

- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the Table 3.

Annex 3. Methods for Figure 6

- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on [view-hub.org](https://www.view-hub.org). The studies were conducted during a period when Omicron was the predominant circulating variant. Only studies providing VE estimates of individual vaccines are included in the plot (studies assessing combined VE of more than one vaccine are excluded). In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.
- For the primary series VE, estimates are only included in the plot for studies that report absolute VE for more than one time period for an individual vaccine. Thirteen studies of VE against Omicron provided only a single cumulative VE estimate for an individual vaccine, which due to varying lengths of time since vaccination are difficult to interpret due to the marked waning of VE over time with omicron.

Annex 4. Summary of Primary Series Vaccine Performance against Variants of Concern (VE data as of 19 May 2022; Neutralization data as of 16 May 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺									Vaccines without WHO EUL ⁺	
	AstraZeneca-Vaxzevria/ SII - Covishield	Beijing CNBG-BBIBP-CorV	Bharat-Covaxin	Cansino - Convidecia ³⁰	Janssen-Ad26.COV 2.S	Moderna-mRNA-1273	Novavax-Nuvaxovid/ SII - Covavax	Pfizer BioNTech-Comirnaty	Sinovac-CoronaVac	Anhui ZI-Recombinant	Gamaleya-Sputnik V
Alpha, Beta, Gamma											
Summary of VE*	see update from 11 January 2022 for details of vaccine performance against Alpha, Beta, and Gamma variants of concern										
Delta											
Summary of VE*	see update from 27 April 2022 for details of vaccine performance against Delta variant of concern										
Omicron											
Summary of VE*	Reduced protection against infection and symptomatic disease; possible reduced protection against for severe disease but limited evidence										
- Severe disease	-	-	-	-	-	↓to↓↓/↓↓↓↓ ₂	-	↓↓to↓↓↓↓ ₅	-	-	-
- Symptomatic disease	↓↓↓ ₁	-	-	-	-	↓↓/↓↓↓↓ ₂	-	↓↓↓ ₃	-	-	-
- Infection	↓↓↓ ₁	-	-	-	-	↓↓↓ ₃	-	↓↓↓ ₃	-	-	-
Neutralization	↓↓↓ ₇	↔to↓↓ ₄	↓↓ ₁	-	↔to↓↓↓ ₄	↓↓↓ ₁₈	-	↓↓↓ ₄₅	↓↓to↓↓↓ ₅	-	↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction³⁰ in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in the study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

COVID-19 Weekly Epidemiological Update

Edition 92, published 18 May 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: Environmental surveillance for SARS-CoV-2 to complement public health surveillance](#)
- [WHO regional overviews](#)

Global overview

Data as of 15 May 2022

Globally, after the continued decline observed since the end of March 2022, new weekly COVID-19 cases have stabilized during the reporting period (9 May to 15 May 2022), with over 3.6 million cases reported, a 1% increase as compared to the previous week (figure 1). On the other hand, the number of new weekly deaths continues to decline, with over 9000 fatalities reported during the same period, representing a 21% decrease as compared to the previous week.

At the regional level, the number of new weekly cases increased in the Eastern Mediterranean Region (+63%), in the Region of the Americas (+26%), in the Western Pacific Region (+14%) and in the African Region (+6%) and decreased in the remaining two regions. The number of new weekly deaths decreased in all the regions except the African Region, where a 48% increase in new weekly deaths was reported.

As of 15 May 2022, over 518 million confirmed cases and over six million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 15 May 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the United States of America (605 547 new cases; +33%), China (389 901 new cases; +94%), Germany (376 959 new cases; -20%), Australia (332 451 new cases; -23%), and Japan (279 620 new cases; +54%).

The highest number of new weekly deaths were reported from the United States of America (1849 new deaths; -27%), Italy (765 new deaths; -16%), the Russian Federation (724 new deaths; -21%), Brazil (689 new deaths; +1%), and France (590 new deaths; -19%).

This week, state media in the Democratic People's Republic of Korea reported a COVID-19 outbreak for the first time.

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 15 May 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Western Pacific	1 366 720 (37%)	14%	57 213 690 (11%)	1 267 (13%)	-10%	227 703 (4%)
Europe	1 266 355 (34%)	-20%	218 195 663 (42%)	3 951 (40%)	-29%	2 002 128 (32%)
Americas	912 887 (25%)	26%	154 815 697 (30%)	3 583 (37%)	-16%	2 733 894 (44%)
South-East Asia	71 347 (2%)	-19%	58 017 061 (11%)	614 (6%)	-24%	787 618 (13%)
Africa	63 149 (2%)	6%	8 897 180 (2%)	258 (3%)	48%	172 091 (3%)
Eastern Mediterranean	19 502 (1%)	63%	21 733 981 (4%)	133 (1%)	-20%	342 544 (5%)
Global	3 699 960 (100%)	1%	518 874 036 (100%)	9 806 (100%)	-21%	6 265 991 (100%)

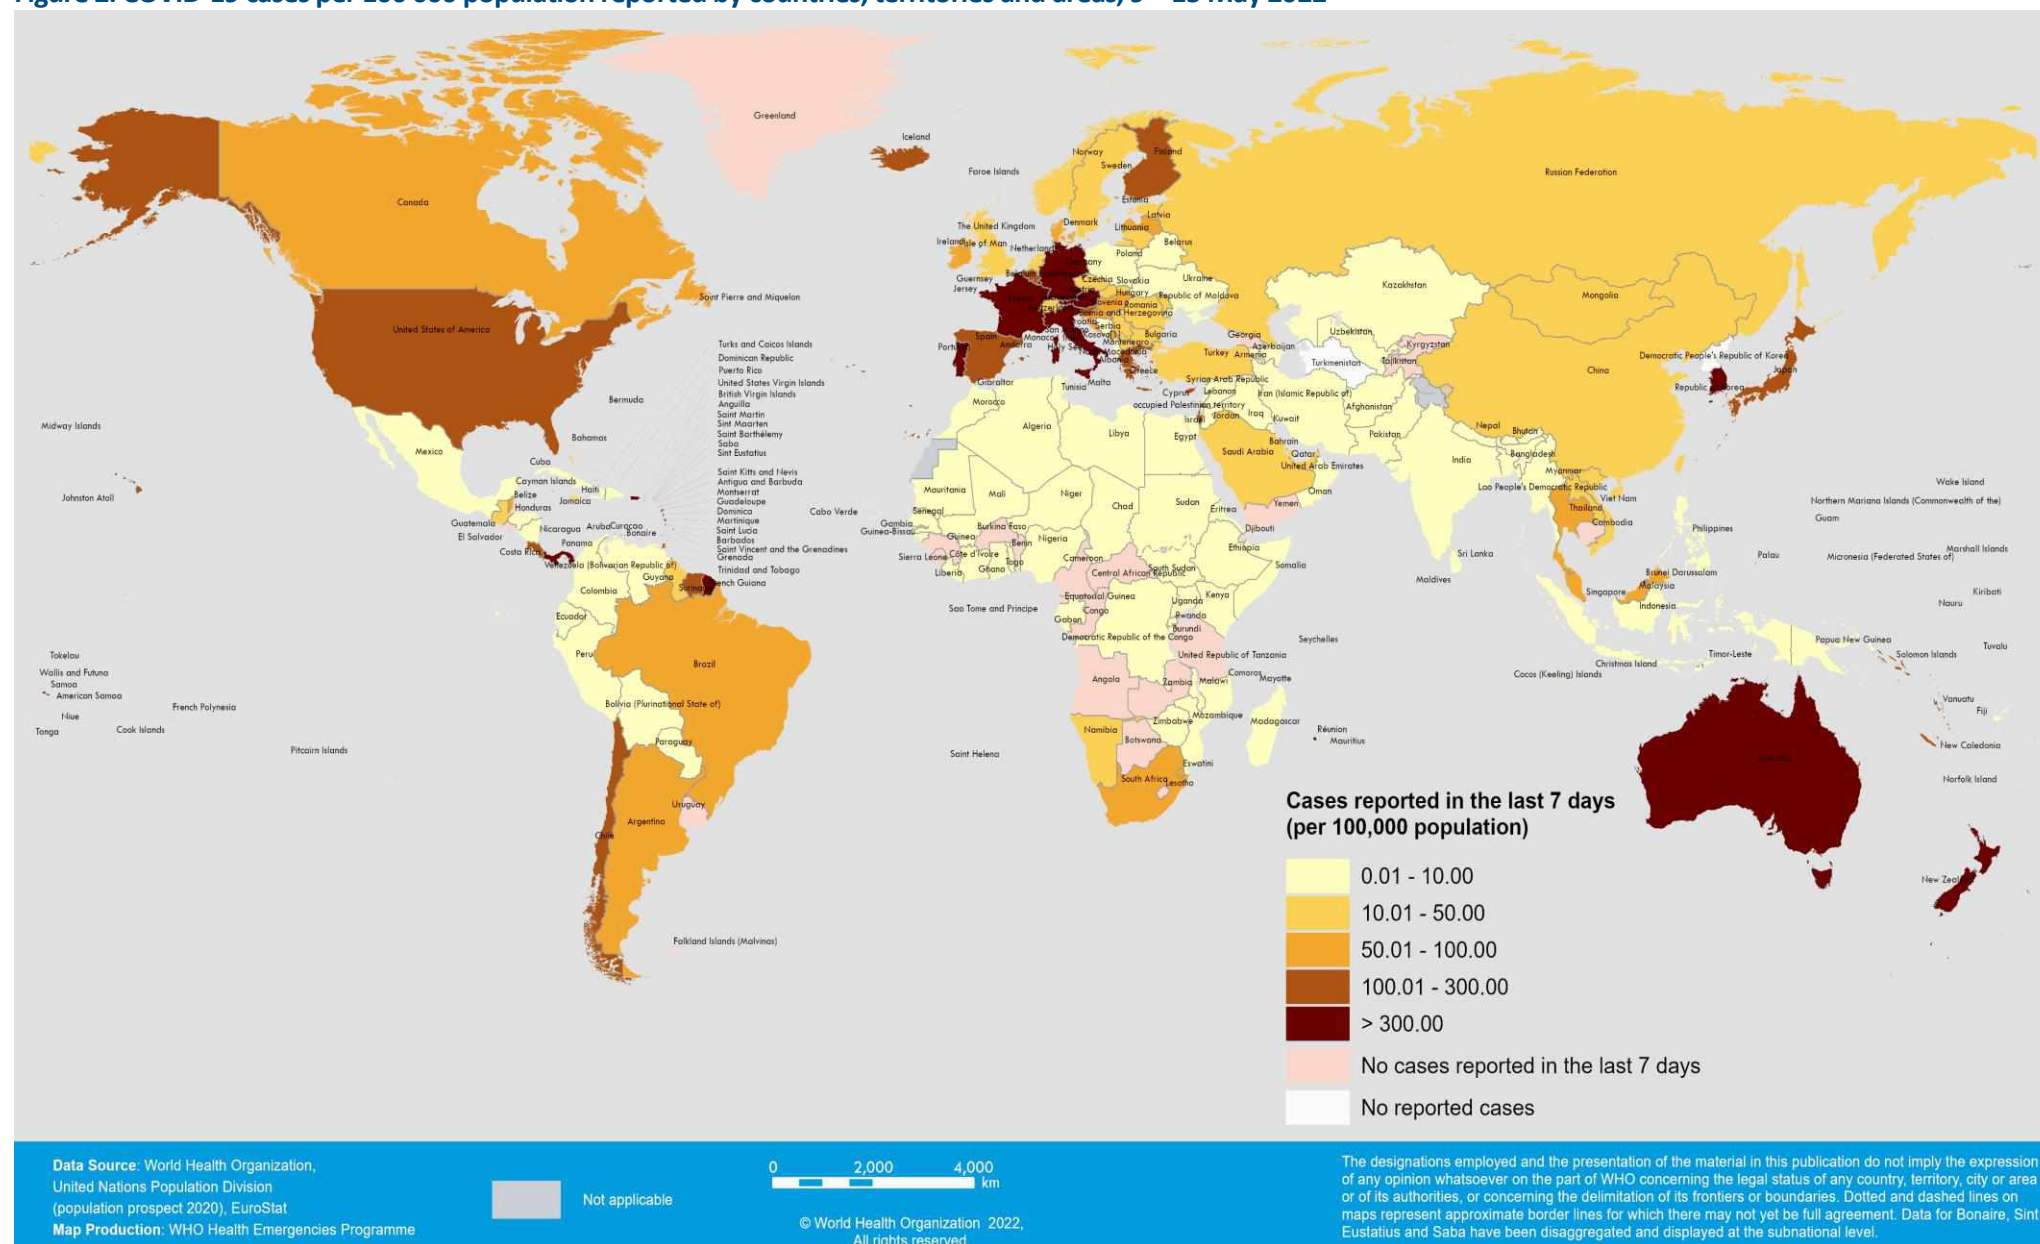

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

The Omicron VOC is the dominant variant circulating globally, accounting for nearly all sequences reported to GISAID. Among Omicron, BA.2 and its descendent lineages (i.e., BA.2.X) are the dominant variants, comprising 97% of all sequences submitted to GISAID from the week of 1 May 2022. Within the last 30 days, BA.1 and its descendent lineages (i.e., BA.1.X), BA.3 and the Delta variant have further declined in prevalence, falling below a global prevalence of <1%.

In recent weeks, Omicron descendent lineages BA.4, BA.5 and BA.2.12.1 (all three with characteristic mutations in the spike region and locus S: L452) have increased in prevalence within the countries in which they were first detected (South Africa and the United States of America, respectively) and spread to additional countries. To date, BA.4 has been detected in 20 countries (1 333 sequences submitted to GISAID), BA.5 has been detected in 19 countries (757 sequences), and BA.2.12.1 has been detected in 38 countries (21 711 sequences). At the global level, BA.4 and BA.5 account for 0.5% and 0.4% of all circulating variants, respectively. Lineage BA.2.12.1 accounts for 10% among BA.2 lineages globally as of 24 April 2022.ⁱ

In South Africa, BA.4 and BA.5 appear to be driving an increase in the numbers of cases, accounting for 89% and 7% of sequences submitted as of 13 May 2022, respectively.¹ Since late April, South Africa has also reported a moderate increase in hospital admissions, although this rise has been significantly lower than that observed during the emergence of Omicron in late 2021. Similarly, the first indications of a rise in the number of cases have been observed in Portugal, which recently confirmed circulation of BA.5. Hospital and ICU admissions remain stable in Portugal as of 13 May. In the United States of America, where the prevalence of BA.2.12.1 is 48%, the numbers of cases and hospitalizations have been rising since April 2022, with a 33% increase in cases and 19% increase in admissions during the week of 9 May, respectively, as compared to the previous week.²

Preliminary modelling by WHO based on sequences submitted to GISAID indicates that BA.4, BA.5 and BA.2.12.1 have a higher growth rate than other circulating variants, such as Delta, BA.1 and BA.2, that may be attributable to increased immune evasion and/or intrinsic transmissibility.

ⁱ Data for the last three weeks (25 April to 17 May 2022) were incomplete due to delays in submission and, thus, were excluded from the analysis.

BA.4, BA.5, and BA.2.12.1 remain lineages monitored by WHO under the umbrella of the Omicron VOC given their current low prevalence at the global level and the insufficient evidence of a change in diseases characteristics, such as severity, associated with these Omicron lineages.

Special Focus: Environmental surveillance for SARS-CoV-2 to complement public health surveillance

The management of the COVID-19 pandemic continues to be challenging, for a number of reasons, including the evolution of the virus and the impact of VOCs on control measures.

The primary source of evidence about the incidence of SARS-CoV-2 infection in any geographic location is the testing of upper respiratory tract samples. However, in an increasing number of settings around the world, routine COVID-19 surveillance programmes have supplemented diagnostic testing with community-scale environmental surveillance (ES) of SARS-CoV-2 in wastewater samples.

Prior to the COVID-19 pandemic, ES to detect circulating pathogens in wastewater had been used extensively in public health, particularly for poliovirus³, typhoid^{4,5} and more recently antimicrobial resistance (AMR).⁶

On 14 April 2022, WHO released interim guidance on [Environmental surveillance for SARS-COV-2 to complement public health surveillance](#) in order to provide Member States with advice on how to establish an effective ES programme for SARS-CoV-2. This includes the minimum requirements for planning and coordinating ES in different resource settings and good practice for data collection, analysis, interpretation and communication.

Applications of environmental surveillance for SARS-CoV-2

Leadership by the public health agencies responsible for the overall COVID-19 response is critical for SARS-COV-2 ES programmes. Health authorities in charge of infectious disease surveillance should have the responsibility to design ES for SARS-CoV-2, coordinate interpretation and communicate findings.

At their most basic, SARS-CoV-2 ES programmes indicate whether, at the level of the community, the virus is above (present) or below (absent) the limits of detection of the testing methods used. This is particularly relevant in zero- or low-prevalence settings to confirm the absence of virus circulation or warn about the (re)emergence of the virus. Most ES programmes in high prevalence settings involve quantification of results to identify trends in SARS-CoV-2 infection in the community. In the most advanced settings, SARS-COV-2 ES programmes can detect emerging variants and monitor circulating variants. These findings can then help target SARS-CoV-2 responses and interventions.

SARS-CoV-2 ES programmes add value by:

- Early warning signalling of SARS-CoV-2 (re)emergence approximately seven days in advance of clinical case detection, including in areas thought to be free of SARS-CoV-2.
- Supporting risk communication to help promote good behaviours – detection of SARS-COV-2 in wastewater can be used to remind the community that the virus is circulating, encourage people to seek diagnostic testing, and reduce complacency about control interventions, such as masking, distancing and vaccination.
- Enabling cost-effective targeting of public health surveillance – hotspot areas with higher SARS-CoV-2 ES signals can be prioritized for the deployment of scarce diagnostic testing resources and implementation of localized restrictions.
- Allowing targeted surveillance for early warning of circulation in vulnerable or high-risk settings, isolated communities, transport vessels, and multi-day events and gatherings.

- Identifying known variants of interest or concern and detecting the emergence of novel variants (albeit challenging in sewage samples).
- Enabling retrospective analysis through banking of samples.

Key considerations for planning and coordination

The components of a wastewater surveillance programme and the requirements for establishing one that is credible and effective include:

- Public health agencies and policymakers who frame the questions that the programme needs to answer and use the information generated to guide decisions.
- Epidemiologists and data managers who collect, manage and interpret data.
- Water, sanitation and environment agencies and municipal authorities responsible for wastewater management and (usually) for sampling who understand wastewater flows and how they relate to residential locations of populations and to public health districts.
- Laboratories which perform the testing, report the results, and undertake quality management, and which have expertise in handling wastewater samples and molecular biology.
- Information technology and communications personnel who undertake spatial mapping and data interpretation, prepare reports and maintain dashboards on behalf of all parties.

The objective of the SARS-CoV-2 ES programme is to inform decision-making processes for SARS-CoV-2 monitoring and management as part of the broader COVID-19 response strategy. This requires linking the SARS-CoV-2 ES programme with other pillars of the response.

Conclusions

There is no universal standard method or approach to ES for SARS-CoV-2. However, there are several communities of practice at the national, regional and global scales, and several proficiency programs, along with many published protocols. The [guidance](#) has more information on the key considerations for data collection, analysis and interpretation.

A range of research projects and innovations are in progress to improve ES for SARS-CoV-2 and other pathogens. ES has the potential to detect novel variants, as well as to increase understanding of the ecology and zoonotic potential (e.g., from sampling of animal rearing operations) of SARS-CoV-2 that has not been identified in human clinical samples, and to monitor wastewater from transport hubs, to support global pandemic intelligence.

WHO regional overviews:

Epidemiological week 9-15 May 2022**

African Region

For almost a month, the African Region has shown an increasing trend in new weekly cases, with over 63 000 new weekly cases reported, a 6% increase as compared to the previous week. Seventeen (35%) countries in the Region reported an increase in cases of over 20%, with some of the greatest proportional increases observed in Malawi (76 vs 30 new cases; +153%), Mozambique (74 vs 32 new cases; +131%) and Mauritania (104 vs 48 new cases; +117%). The highest numbers of new cases were reported from South Africa (51 547 new cases; 86.9 new cases per 100 000; +17%), Réunion (7865 new cases; 878.5 new cases per 100 000; -28%), and Zimbabwe (674 new cases; 4.5 new cases per 100 000; +58%).

The Region reported over 250 new weekly deaths, a 48% increase as compared to the previous week. The highest numbers of new deaths were reported from South Africa (237 new deaths; <1 new death per 100 000; +55%), Zimbabwe (eight new deaths; <1 new death per 100 000; +100%), and Réunion (six new deaths; <1 new death per 100 000; -14%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has continued to report an increasing trend since mid-April 2022, with over 912 000 new weekly cases reported, a 26% increase as compared to the previous week. Twenty-six (46%) countries in the Region reported increases in new cases of 20% or greater, with some of the greatest proportional increases observed in Suriname (615 vs 57 new cases; +979%), Falkland Islands (Malvinas) (734 vs 211 new cases; +248%) and Guyana (233 vs 83 new cases; +184%). The highest numbers of new cases were reported from the United States of America (605 547 new cases; 182.9 new cases per 100 000; +33% increase), Brazil (120 831 new cases; 56.8 new cases per 100 000; +9%), and Argentina (33 989 new cases; 75.2 new cases per 100 000; +93%).

The number of new weekly deaths in the Region decreased by 16% as compared to the previous week, with over 3500 new deaths reported. The highest numbers of new deaths were reported from the United States of America (1849 new deaths; <1 new death per 100 000; -27%), Brazil (689 new deaths; <1 new death per 100 000; +1%), and Canada (501 new deaths; 1.3 new deaths per 100 000; +3%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

After the declining trend observed since mid-February 2022, the Eastern Mediterranean Region reported over 19 000 new weekly cases, representing a 63% increase as compared to the previous week. Nine (41%) countries in the Region reported increases in new cases of 20% or greater, with some of the greatest proportional increases observed in Libya (35 vs three new cases; +1067%), Afghanistan (320 vs 44 new cases; +627%) and Saudi Arabia (3719 vs 1065; +249%). The highest numbers of new cases were reported from Bahrain (4915 new cases; 288.9 new cases per 100 000; +46%), Saudi Arabia, and the Islamic Republic of Iran (2982 new cases; 3.6 new cases per 100 000; -2%).

The number of new weekly deaths in the Region decreased by 20% when compared to the previous week, with over 130 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (51 new deaths; <1 new death per 100 000; -38%), Egypt (28 new deaths; <1 new death per 100 000; -20%), and Saudi Arabia (15 new deaths; <1 new death per 100 000; +25%).

Updates from the [Eastern Mediterranean Region](#)

European Region

In the European region, cases have continued to decrease since mid-March 2022, with over 1.2 million new weekly cases, a 20% decrease as compared to the previous week. Five (8.2%) countries in the Region reported increases in new cases of 20% or greater, with some of the greatest proportional increases observed in Ukraine (3590 vs 200 new cases; +1695%), Hungary (6748 vs 2183 new cases; +209%) and Portugal (115 560 vs 85068 new cases; +36%). The cases in Ukraine should be interpreted carefully due to the impact of the ongoing conflict on testing capacities. The highest numbers of new cases were reported from Germany (376 959 new cases; 453.3 new cases per 100 000; -20%), Italy (262 374 new cases; 439.9 new cases per 100 000; -14%), and France (217 932 new cases; 335.1 new cases per 100 000; -18%).

The Region reported just over 3900 new deaths, a 29% decrease as compared to the previous week. The highest numbers of new deaths were reported from Italy (765 new deaths; 1.3 new deaths per 100 000; -16%), the Russian Federation (724 new deaths; <1 new death per 100 000; -21%), and France (590 new deaths; <1 new death per 100 000; -19%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 71 000 new cases and 614 new deaths, decreases of 19% and 24% respectively as compared to the previous week. All countries except for Bangladesh (213 vs 83 new cases; +156%) and Indonesia (2345 vs 1391 new cases; +68%) reported a decrease in weekly cases. The highest numbers of new cases were reported from Thailand (48 996 new cases; 70.2 new cases per 100 000; -21%), India (19 405 new cases; 1.4 new cases per 100 000; -16%), and Indonesia (2345 new cases; <1 new case per 100 000; +69%).

The highest numbers of new weekly deaths in the Region were reported from Thailand (384 new deaths; <1 new death per 100 000; -18%), India (150 new deaths; <1 new death per 100 000; -32%), and Indonesia (77 new deaths; <1 new death per 100 000; -29%).

A first outbreak of COVID-19 has been reported in the Democratic People's Republic of Korea through official media on 12 May 2022. However, at this time no counts of confirmed cases or deaths are available.

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region had shown decreasing trends in new weekly cases since mid-March 2022. However, an increase has been observed in weekly new cases in the last two weeks, with over 1.3 million new cases, a 14% increase as compared to the previous week. Nine (31%) countries in the Region reported increases in new cases of 20% or greater, with some of the greatest proportional increases observed in Papua New Guinea (279 vs 22 new cases; +1168%), Brunei Darussalam (1784 vs 77 new cases; +129%) and Malaysia (19 137 vs 8732 new cases; +119%). The highest numbers of new cases were reported from China (389 901 new cases; 26.5 new cases per 100 000; +94%), Australia (332 451 new cases; 1303.7 new cases per 100 000; -23%), and Japan (279 620 new cases; 221.1 new cases per 100 000; +54%).

The Region reported just over 1200 new weekly deaths, a 10% decrease as compared to the previous week. The highest numbers of new deaths were reported from Republic of Korea (349 new deaths; <1 new death per 100 000; -28%), Australia (267 new deaths; <1 new death per 100 000; +16%), and Japan (254 new deaths; <1 new death per 100 000; +17%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 91, published 11 May 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 8 May 2022

Globally, the number of new COVID-19 cases and deaths has continued to decline since the end of March 2022. During the week of 2 through 8 May 2022, over 3.5 million cases and over 12 000 deaths were reported, decreases of 12% and 25% respectively, as compared to the previous week (Figure 1).

At the regional level, the number of new weekly cases increased in the Region of the Americas (+14%) and in the African Region (+12%), remained stable in the Western Pacific Region (+1%), and decreased in the remaining three regions. The number of new weekly deaths increased in the African Region (+84%), remained stable in the Region of the Americas (+3%), while decreasing trends were reported in the other four regions.

As of 8 May 2022, over 514 million confirmed cases and over six million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 8 May 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the United States of America (451 414 new cases; +19%), Australia (431 410 new cases; +59%), Germany (427 044 new cases; -29%), Italy (304 573 new cases; -21%), and the Republic of Korea (268 749 new cases; -29%).

The highest number of new weekly deaths were reported from the United States of America (2 652 new deaths; +19%), the Russian Federation (915 new deaths; -19%), Italy (910 new deaths; +1%), France (732 new deaths; -19%), and Brazil (681 new deaths; -20%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 8 May 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	1 482 775 (42%)	-26%	216 726 575 (42%)	5 137 (43%)	-24%	1 996 028 (32%)
Western Pacific	1 197 250 (34%)	1%	55 846 326 (11%)	1 407 (12%)	-32%	226 437 (4%)
Americas	709 439 (20%)	14%	153 884 155 (30%)	4 344 (36%)	3%	2 729 790 (44%)
South-East Asia	87 674 (2%)	-29%	57 945 672 (11%)	805 (7%)	-70%	787 004 (13%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

Sequence availability

Figure 4 shows the number of cases reported and the number of SARS-CoV-2 sequences submitted to GISAID between 1 January 2020 and 5 May 2022, globally and by WHO region. Globally, the number of shared sequences has increased over time as countries strengthened sequencing capacity and intensified genomic surveillance in response to the ongoing pandemic and following the emergence of new VOCs. However, after reaching a peak in January 2022, the number of shared sequences fell to levels similar to those observed in June 2021, just after Delta started to spread and was designated a VOC. The recent declining trend is similar across WHO regions. It is unclear whether this decline is primarily driven by the reduction in the true number of cases, or changes in testing strategies in several countries, or a combination of both. A change in the proportion of cases sequenced per country may have also resulted in a decrease of available data.

Figure 4. The number of cases reported and the number of sequences submitted to GISAID, from 1 January 2020 to 10 May 2022, globally and by WHO region

Variant circulation

WHO continues to monitor circulating SARS-CoV-2 variants, including Omicron sublineages, thanks to the continued and transparent sharing of information from Member States, Regional Offices, partners and technical experts, such as the members of the Technical Advisory Group on SARS-CoV-2 Virus Evolution (TAG-VE).

The Omicron VOC remains the dominant variant circulating globally, accounting for nearly all sequences reported to GISAID in the last 30 days. Of note is the very low proportions of 'previously circulating VOCs' and of the Delta VOC. With variant diversification, Omicron sublineages have continued to be identified; however, only a few of these sublineages appear to have a growth advantage. These findings need to be interpreted with caution, as differences in sequence capacity across regions and countries may confound such interpretations and global distributions.

Characteristics of Omicron

Available evidence on the phenotypic impacts of VOCs has been reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last update on 5 April 2022](#), there have been several new publications on the phenotypic characteristics of VOCs, including literature on Omicron (Table 2). Some of these studies have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Table 2: Summary of current evidence on Omicron

Domain	Indicator	Main results
Epidemiology	Impact on transmission	Previous analyses of GISAID data ¹ consistently showed Omicron having a steadily increasing growth rate advantage over Delta in all countries with sufficient sequence data (last update included data available up to 4 April 2022). Applying this approach yielded results in favour of a growth rate advantage of the Omicron sublineage BA.2 over the sublineage BA.1. However, the recent identification of several sublineages of the Omicron variant does not yet allow for updated estimates to be obtained. A recent modelling study in India ² that included samples submitted to GISAID found a higher basic reproductive number for BA.2 (2.45, 95% highest posterior density [HPD] intervals: 1.53-3.76) compared to BA.1 (1.70, 95% HPD: 1.43-2.46).
	Impact on disease severity	Omicron had been associated with lower severity when compared to Delta across several settings. ³⁻⁷ A recent study conducted in England, United Kingdom ⁸ reported a lower risk of emergency unit attendance following infection with Omicron compared to infection with Delta (HR: 0.39 (95% CI: 0.30 – 0.51; P<.0001). On the contrary, a study in Indonesia ⁹ and the United States ¹⁰ found no difference in hospitalisation and mortality following infection with Omicron compared to infection with Delta. This suggests that the severity of Omicron infection could vary in different settings, although vaccination coverage, population immunity, age distribution and other factors could influence disease severity.
Immune response	Impact on reinfection	Higher rates of reinfection were initially reported for Omicron as compared to other SARS-CoV-2 VOCs. However, a protective effect of previous infection was reported in a recent study conducted in the United States of America ¹¹ , which found increased antibody titres and neutralisation activity (79.5%) against Omicron among vaccinated solid organ transplant recipients who were previously infected with SARS-CoV-2, compared to those who had no previous infection (34%). Similarly, another study conducted in Canada ¹² reported that infection with a different SARS-CoV-2 variant resulted in a reduction in the risk of infection (44%; 95% CI: 38-48) and hospitalisation (81%; 95%CI: 66-89) with Omicron. Previous infection with one of the Omicron sublineages has been suggested as potentially conferring protection against infection with other Omicron sublineages: 94.9% (95% CI: 88.4-97.8%) protection against BA.2 following infection with BA.1, and 85.6% (95% CI: 77.4-90.9%) protection against BA.1 following infection with BA.2. ¹³
	Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant.
	Impact on antibody responses	There have been no new studies on antibody responses to BA.2. Previous studies have reported lower neutralising antibody titers to BA.1 and BA.2 compared to the index virus, and similar responses for BA.1 and BA.2. ^{14,15} Similar non-neutralising antibody responses to BA.1 and BA.2 were also reported in vaccinated individuals. ¹⁶ However, another study reported reduced vaccine-induced and infection-induced neutralization of BA.1 and BA.2, with higher neutralisation activity against BA.2 compared to BA.1. ¹⁷ Therefore, these results indicate lower humoral responses to BA.1 and BA.2, but inconsistent findings regarding BA.1 versus BA.2.
Diagnostic tools	Impact on PCR assays	BA.1, BA.4 and BA.5 contain the 69-70 deletion, responsible for S-gene target failure. Most BA.2 sequences lack the 69-70 deletion and will be positive for the S-gene target. PCR assays that include multiple gene targets maintain their accuracy to detect Omicron. Specifically, early assessments of several PCR tests predicted limited impact of the Omicron variant (BA.1) on the accuracy of these assays. ^{18,19}

	Impact on Rapid Diagnostic tests	Though many studies have reported comparable sensitivity of Ag-RDTs to detect Omicron compared to other VOCs or the index virus ^{20–22} , others have shown reduced sensitivity. ^{23,24} These contradictory findings will require further investigation.
Impact on treatment	Impact on antivirals	Consistent with preliminary data showing no difference in the effectiveness of antiviral agents (Remdesivir, Molnupiravir, and PF-07304814) against the Omicron variant, a recent review reported similar efficacy of antiviral agents against Omicron and previous SARS-CoV-2 variants. ²⁵
	Impact on biologicals	Initially, studies on the effectiveness of monoclonal antibodies for treating patients with Omicron reported conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduced effectiveness of other monoclonal antibodies. ^{26–29} However, additional preclinical evidence shows reduced neutralizing activity of sotrovimab against the BA.2 sublineage and lack of efficacy of casirivimab-imdevimab against the BA.1 Omicron sublineage (see WHO Therapeutics living guideline). A recent phase 2 clinical trial ³⁰ found a shorter time to hospital discharge among patients on high titre convalescent plasma compared to patients on standard titre (HR = 1.94 [95% CI 1.05, 3.58], p=0.02).
	Other treatment options	There is no evidence available on the effectiveness of interleukin-6 receptor blockers and corticosteroids for the management of severe patients with Omicron.

Figure 5 summarizes the impact of Omicron variant on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Since the last [update](#), two new studies have been added to the figures.^{31,32} Both studies (not yet peer reviewed) provided new VE data on both AstraZeneca-Vaxzevria and Pfizer BioNTech-Comirnaty. Additional information on vaccine performance against VOCs can also be found in Annex 4.

Figure 5. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

*Indicates booster dose vaccine effectiveness evaluated using persons completing primary series as reference group, rather than unvaccinated persons. Abbreviations: pop=population; HCW=healthcare workers. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the summary table of VE effectiveness studies on [view-hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes severe disease, hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, nine negative point estimates for the primary series are not shown in the Omicron plot: two estimates from reference #144 against infection at 3 to <6 months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), two estimates from reference #179 against symptomatic disease at 6+ months (Pfizer BioNTech-Comirnaty and Moderna-Spikevax), and five estimates from reference #240 (one AstraZeneca-Vaxzevria estimate at 3 to <6 months; three AstraZeneca-Vaxzevria estimates and one Pfizer BioNTech estimate at 6+ months).

Interpretation of the results of the VE for the Omicron variant

To date, 23 studies from ten countries (Brazil, Canada, Czech Republic, Denmark, Finland, Israel, Qatar, South Africa, the United Kingdom and the United States of America) have assessed the duration of protection of five vaccines against the Omicron variant (six studies assessed VE of primary series vaccination only, six assessed VE of a booster dose vaccination only, and 11 assessed both). Findings from these studies show reduced VE of COVID-19 primary series vaccines against the Omicron variant for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for other four VOCs. Importantly though, in the majority of studies VE estimates against the Omicron variant remain higher for *severe disease*. Booster vaccination substantially improves VE for all outcomes and for all combinations of schedules with estimates available, for both primary series and booster vaccination. However, studies that assess VE of booster vaccination beyond six months are needed to evaluate the longer duration of protection.

For *severe disease*, within the first three months of primary series vaccination, seven of 12 (58%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty) were $\geq 70\%$. Of the two studies available for vector vaccines, one reported a VE of $<70\%$ for AstraZeneca-Vaxzevria, and the other reported a VE of $<50\%$ for Janssen-Ad26.COVS.2.S. One study available for inactivated vaccines (Sinovac-CoronaVac) reported a VE of 50%. Beyond three months after vaccination, 12 of 27 (44%) VE estimates for the mRNA vaccines were $\geq 70\%$ while 18 (77%) were $\geq 50\%$, one of the 12 (8%) VE estimates for AstraZeneca-Vaxzevria was $\geq 70\%$ while eight (67%) were $\geq 50\%$, and the two available VE estimates for Sinovac-CoronaVac were $\geq 50\%$; both estimates for Janssen-Ad26.COVS.2.S beyond three months of vaccination were $<50\%$.

A booster dose improved VE estimates against *severe disease* in all studies, with only one estimate for Pfizer BioNTech-Comirnaty and one for Janssen-Ad26.COVS.2.S as the booster dose below 70%, between 14 days and three months of receipt of the booster dose (33 estimates evaluated an mRNA booster, two estimates a booster dose of Janssen-Ad26.COVS.2.S, and one estimate a booster dose of Sinovac-CoronaVac). At three to six months post mRNA booster, 18 of 20 (90%) estimates showed VE $\geq 70\%$ (an mRNA vaccine was given as the primary series in 13 of the 20 estimates while AstraZeneca-Vaxzevria and Sinovac-CoronaVac were given as the primary series for six and one of the twenty estimates, respectively).

VE estimates against *symptomatic disease* and *infection* within the first three months of primary series vaccination tended to be lower than those against *severe disease*, and VE decreased more substantially over time. For *symptomatic disease* within the first three months of primary series vaccination, only three of 13 (23%) VE estimates for the mRNA vaccines were $\geq 70\%$, and seven (54%) were $\geq 50\%$; all the three (100%) VE estimates for AstraZeneca-Vaxzevria and the single estimate for Sinovac (CoronaVac) were below 50%. Beyond three months after vaccination, none of the 28 VE estimates were $\geq 50\%$ (20 estimates evaluated mRNA vaccines, six evaluated AstraZeneca-Vaxzevria, and two evaluated Sinovac-CoronaVac). An mRNA booster after completion of a primary series of an mRNA vaccine, AstraZeneca-Vaxzevria, or Sinovac-CoronaVac, improved VE estimates against *symptomatic disease*, with four of 21 (19%) VE estimates $\geq 70\%$ and 16 (76%) estimates $\geq 50\%$, between 14 days and three months post booster. However, booster dose protection declined with time since vaccination, with only one of twelve (8%) available estimates indicating a VE of $\geq 50\%$ at three to six months following receipt of an mRNA booster dose. Estimates for a booster dose of AstraZeneca-Vaxzevria (one estimate) and Sinovac-CoronaVac (one estimate) three to six months post vaccination indicated VE of $<50\%$. VE estimates against *infection* showed a similar pattern as those against *symptomatic disease*.

WHO regional overviews:

Epidemiological week 2-8 May 2022**

African Region

For the third consecutive week, the African Region has shown an increasing trend with just under 57 000 new weekly cases reported, a 12% increase as compared to the previous week. Six (12%) countries in the Region reported an increase of over 20% in cases, with some of the greatest proportional increases observed in Mauritania (48 vs 5 new cases; +860%), Niger (45 vs 27 new cases; +67%) and Nigeria (50 vs 31 new cases; +61%). The highest numbers of new cases were reported by South Africa (43 977 new cases; 74.1 new cases per 100 000; +36%), Réunion (10 931 new cases; 1220.9 new cases per 100 000; -15%), and Burundi (448 new cases; 3.8 new cases per 100 000; -64%).

The Region reported 166 new weekly deaths, an 84% increase as compared to the previous week. The highest numbers of new deaths were reported from South Africa (153 new deaths; <1 new death per 100 000 population; +135%), Réunion (seven new deaths; <1 new death per 100 000; similar to the previous week's figures), and Eswatini (two new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has continued a gradual increasing trend observed since mid-April 2022, with over 709 000 new weekly cases reported, a 14% increase as compared to the previous week. Nineteen (34%) countries in the Region reported increases in new cases of 20% or greater, with some of the greatest proportional increases observed in Falkland Islands (Malvinas) (211 vs 29 new cases; +628%), Montserrat (236 vs 39 new cases; +505%) and the United States Virgin Islands (818 vs 258 new cases; +217%). The highest numbers of new cases were reported from the United States of America (451 414 new cases; 136.4 new cases per 100 000; +19%), Brazil (110 866 new cases; 52.2 new cases per 100 000; +18%), and Canada (41 069 new cases; 108.8 new cases per 100 000; -25%).

The number of new weekly deaths in the Region was similar to the previous week (+3%), with over 4300 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2652 new deaths; <1 new death per 100 000; +19%), Brazil (681 new deaths; <1 new death per 100 000; -20%), and Canada (486 new deaths; 1.3 new deaths per 100 000; +2%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline after reaching a peak in early February 2022, with just under 12 000 new weekly cases reported last week, a 28% decrease as compared to the previous week. However, Saudi Arabia and the Syrian Arab Republic reported increases in new weekly cases of 57% (1065 vs 679 new cases) and 48% (31 vs 21 new cases), respectively. The highest numbers of new cases were reported from Bahrain (3376 new cases; 198.4 new cases per 100 000; +17%), the Islamic Republic of Iran (3048 new cases; 3.6 new cases per 100 000; -50%), and the United Arab Emirates (1455 new cases; 14.7 new cases per 100 000; -13%).

The number of new weekly deaths in the Region decreased by 26% when compared to the previous week, with 166 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (82 new deaths; <1 new death per 100 000; -32%), Egypt (35 new deaths; <1 new death per 100 000; -17%), and Tunisia (16 new deaths; <1 new death per 100 000; -6%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After the increase observed during the first half of March 2022, new weekly cases have continued to decrease in the European Region, with over 1.4 million new cases reported, a 26% decrease as compared to the previous week. However, the Republic of Moldova and Gibraltar reported increases in new weekly cases of 149% (547 vs 220 new cases) and 25% (161 vs 129 new cases), respectively. The highest numbers of new cases were reported from Germany (427 044 new cases; 513.5 new cases per 100 000; -29%), Italy (304 573 new cases; 510.7 new cases per 100 000; -21%), and France (267 172 new cases; 410.8 new cases per 100 000; -30%).

The number of new deaths has continued to decrease in the Region, with just over 5000 new deaths reported this week, a 24% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (915 new deaths; <1 new death per 100 000; -19%), Italy (910 new deaths; 1.5 new deaths per 100 000; +1%), and France (732 new deaths; 1.1 new death per 100 000; -19%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 87 000 new weekly cases, a 29% decline as compared to the previous week, continuing the decreasing trend observed since January 2022. However, Nepal and Timor-Leste reported increases in new weekly cases of 34% (114 vs 85 new cases) and 27% (14 vs 2 new cases), respectively. The highest numbers of new cases were reported from Thailand (62 366 new cases; 89.3 new cases per 100 000; -35%), India (23 006 new cases; 1.7 new cases per 100 000; +6%), and Indonesia (1391 new cases; <1 new case per 100 000; -52%).

With 805 new weekly death reported last week in the Region, weekly deaths decreased by 70% as compared to the previous week, during which India reported a delayed batch of deaths. The highest numbers of new deaths were reported from Thailand (471 new deaths; <1 new death per 100 000; -44%), India (221 new deaths; <1 new death per 100 000; -87%), and Indonesia (108 new deaths; <1 new death per 100 000; -38%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region has shown decreasing trends in new weekly cases and deaths after peaks observed in mid-March 2022. However, the trend in new weekly cases has stabilized during the week ending on 8 May, with just under 1.2 million new weekly cases reported, which was similar to the previous week (+1%). Six (19%) countries in the Region reported an increase of 20% or greater, with some of the largest increases observed in China (200 968 vs 81 989 new cases; +145%), New Caledonia (232 vs 96 new cases; +142%) and Australia (431 410 vs 271 216 new cases; +59%). The sharp increase in Australia is due to the revision of the number of cases confirmed by rapid antigen detection tests. Australia also reported the highest numbers of new cases, followed by the Republic of Korea (268 749 new cases; 524.2 new cases per 100 000; -29%), and China.

The number of new weekly deaths shows a decrease of 32% as compared to the previous week, with over 1400 new deaths reported. The highest numbers of new deaths were reported from the Republic of Korea (485 new deaths; <1 new death per 100 000; -35%), Australia (231 new deaths; <1 new death per 100 000; -9%), and Japan (218 new deaths; <1 new death per 100 000; -23%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 2. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Annex 4 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for

AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., >90%).

- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the Annex 4.

Annex 3. Methods for Figure 5

- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when Omicron was the predominant circulating variant. Only studies providing VE estimates of individual vaccines are included in the plot (studies assessing combined VE of more than one vaccine are excluded). In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.
- For the primary series VE, estimates are only included in the plot for studies that report VE for more than one time period for an individual vaccine. Thirteen studies of VE against Omicron provided only a single cumulative VE estimate for an individual vaccine, which due to varying lengths of time since vaccination are difficult to interpret due to the marked waning of VE over time with omicron.

Annex 4. Summary of Primary Series Vaccine Performance against Variants of Concern (VE data as of 5 May 2022; Neutralization data as of 2 May 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺								Vaccines without WHO EUL ⁺	
	AstraZeneca- Vaxzevria/ SII - Covishield	Beijing CNBG- BBIBP-CorV	Bharat-Covaxin	Janssen- Ad26.COV 2.S	Moderna- mRNA-1273	Novavax- Nuvaxovid/ SII - Covavax	Pfizer BioNTech- Comirnaty	Sinovac- CoronaVac	Anhui ZL- Recombinant	Gamaleya- Sputnik V
Alpha, Beta, Gamma										
Summary of VE*	see update from 11 January 2022 for details of vaccine performance against Alpha, Beta, and Gamma variants of concern									
Delta										
Summary of VE*	see update from 27 April 2022 for details of vaccine performance against Delta variant of concern									
Omicron										
Summary of VE*	Reduced protection against infection and symptomatic disease; possible reduced protection against for severe disease but limited evidence									
- Severe disease	-	-	-	-	↓↓to↓↓/↓↓↓↓ ₂	-	↓↓↓to↓↓↓↓ ₅	-	-	-
- Symptomatic disease	↓↓↓↓ ₁	-	-	-	↓↓↓/↓↓↓↓ ₂	-	↓↓↓↓ ₃	-	-	-
- Infection	↓↓↓↓ ₁	-	-	-	↓↓↓↓ ₃	-	↓↓↓↓ ₃	-	-	-
Neutralization	↓↓↓↓ ₇	↔to↓↓↓↓ ₃	↓↓↓ ₁	↔to↓↓↓↓ ₄	↓↓↓↓ ₁₈	-	↓↓↓↓ ₄₅	↓↓↓to↓↓↓↓ ₅	-	↓↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction³²ⁿ in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in the study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

COVID-19 Weekly Epidemiological Update

Edition 90, published 4 May 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 1 May 2022

Globally, the number of new COVID-19 cases and deaths has continued to decline since the end of March 2022. During the week of 25 April through 1 May 2022, over 3.8 million cases and over 15 000 deaths were reported, decreases of 17% and 3% respectively, as compared to the previous week (Figure 1).

However, not all the Regions reported decreasing trends: the number of new weekly cases increased in the African Region (+31%) and in the Region of the Americas (+13%), while the number of new weekly deaths increased in the South-East Asia Region (+69%) largely due to a delay in the reporting of deaths from India.

As of 1 May 2022, over 500 million confirmed cases and over six million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing their COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 1 May 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from Germany (558 958 new cases; - 24%), Italy (384 825 new cases; -8%), France (382 208 new cases; -30%), the Republic of Korea (380 455 new cases; - 35%), and the United States of America (372 167 new cases; +27%).

The highest number of new weekly deaths were reported from the United States of America (2 199 new deaths; - 5%), India (1 650 new deaths; +273%), the Russian Federation (1 129 new deaths; -19%), France (900 new deaths; +2%), and Italy (898 new deaths; -11%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 1 May 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	1 899 829 (49%)	-22%	215 107 376 (42%)	6 456 (41%)	-16%	1 988 860 (32%)
Western Pacific	1 188 038 (31%)	-20%	54 652 929 (11%)	2 063 (13%)	-8%	225 031 (4%)
Americas	616 348 (16%)	13%	153 159 475 (30%)	4 200 (27%)	<1%	2 724 151 (44%)
South-East Asia	123 210 (3%)	-24%	57 857 765 (11%)	2 669 (17%)	69%	786 199 (13%)
Africa	49 373 (1%)	31%	8 772 209 (2%)	84 (1%)	-56%	171 652 (3%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are strongly encouraged to investigate and report newly emerging variants and their impact.

Geographic spread and prevalence of VOCs

The Omicron variant of concern is the dominant variant circulating globally, accounting for nearly all sequences reported to GISAID. Since its designation as a VOC by WHO on 26 November 2021, Omicron has continued to evolve, leading to variants with slightly different genetic constellations of mutations. Each constellation may differ in the public health risk it poses, including the change in epidemiology and or the severity profile. The main features of Omicron sublineages are the high growth advantage over other variants, which is mainly driven by immune evasion. Omicron sublineages have led and are still leading to a high number of cases and, as a result, to a high number of hospitalizations and deaths.

Three Omicron sublineages BA.4, BA.5 and BA.2.12.1 have acquired a few additional mutations that may impact their characteristics (BA.4 and BA.5 have the del69/70, L452R and F486V mutations; BA.2.12.1 has the L452Q and S704L mutations). Based on GISAID data and reports from WHO regional offices and countries, the number of cases and the number of countries reporting the detection of these three variants are rising. Limited evidence to date, does not indicate a rise in hospital admissions or other signs of increased severity. Preliminary data from South Africa using S gene target failure data (absent in BA.2, present in BA.4 and BA.5) indicate no difference in the risk of hospitalization for BA.4 and BA.5, as compared to BA.1; however, the short follow-up of BA.4 and BA.5 cases does not allow for conclusions on disease severity of these sublineages to be drawn at this stage.

WHO continues to closely monitor the BA.4, BA.5, and BA.2.12.1 variants as part of Omicron VOC and provide further updates as more evidence on severity becomes available. WHO requests countries to continue to be vigilant, to monitor and report sequences, as well as to conduct independent and comparative analyses of the different emerging variants.

WHO regional overviews:

Epidemiological week 25 April - 1 May 2022**

African Region

Following the decreasing trend observed since January 2022, the Africa Region showed an increase in cases for the second consecutive week (+31% as compared to the previous week), with over 49 000 new weekly cases reported. Twelve (24%) countries in the region reported an increase of over 20% in cases, with some of the greatest proportional increases observed in Burundi (1253 vs 343 new cases; +265%), Rwanda (45 vs 18 new cases; +150%) and Eswatini (359 vs 186 new cases; +93%). The highest numbers of new cases were reported from South Africa (32 236 new cases; 54.4 new cases per 100 000 population; +67%), Réunion (12 889 new cases; 1439.6 new cases per 100 000; -7%), and Burundi (1253 new cases; 10.5 new cases per 100 000; +265%).

The Region reported 84 new weekly deaths, a 56% decrease as compared with the previous week. The highest numbers of new deaths were reported from South Africa (65 new deaths; <1 new death per 100 000 population; -58%), Réunion (seven new deaths; <1 new death per 100 000; -36%), and Seychelles (three deaths; 3.1 new deaths per 100 000; similar to the previous week's figures).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas shows an increasing trend for the third consecutive week, with over 616 000 new cases reported, a 13% increase as compared to the previous week. Twenty-two (39%) countries in the Region reported increases in new cases of 20% or greater, with the largest increases observed in Montserrat (39 vs one new case; +3800), Haiti (42 vs 15 new cases; +180%) and Costa Rica (4290 vs 1642 new cases; +161%). The highest numbers of new cases were reported from the United States of America (372 167 new cases; 112.4 new cases per 100 000; +27%), Brazil (94 345 new cases; 44.4 new cases per 100 000; +3%), and Canada (54 519 new cases; 144.5 new cases per 100 000; -14%).

The number of new weekly deaths in the Region remained similar to the number reported during the previous week, with 4200 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2199 new deaths; <1 new death per 100 000; -5%), Brazil (853 new deaths; <1 new death per 100 000; +31%), and Canada (477 new deaths; 1.3 new deaths per 100 000; +6%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline after reaching a peak in early February 2022. Over 16 000 new weekly cases were reported last week, a 29% decrease as compared to the previous week. However, Djibouti reported an increase in new weekly cases of 54% (29 vs 13 new cases). The highest numbers of new cases were reported from the Islamic Republic of Iran (6141 new cases; 7.3 new cases per 100 000; -41%), Bahrain (2876 new cases; 169.0 new cases per 100 000; -6%), and the United Arab Emirates (1679 new cases; 17.0 new cases per 100 000; +3%).

The number of new weekly deaths in the Region decreased by 21% when compared to the previous week, with 223 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (121 new deaths; <1 new death per 100 000; -25%), Egypt (42 new deaths; <1 new death per 100 000; similar to the previous week), and Tunisia (17 new deaths; <1 new death per 100 000; -29%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After the increase observed during the first half of March 2022, new weekly cases have continued to decrease in the European Region. Just under 1.9 million new cases were reported, a 22% decrease as compared to the previous week. However, six (10%) countries in the Region reported increases in new cases of 20% or greater, with the largest increases observed in Cyprus (9901 vs 6115 new cases; +62%), Spain (110 116 vs 76 005 new cases; +45%) and Kazakhstan (174 vs 125 new cases; +39%). The highest numbers of new cases were reported from Germany (558 958 new cases; 672.1 new cases per 100 000; -24%), Italy (384 825 new cases; 645.2 new cases per 100 000; -8%), and France (382 208 new cases; 587.7 new cases per 100 000; -30%).

The number of new deaths has continued to decrease in the Region, with just over 6400 new deaths reported this week, a 16% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (1129 new deaths; <1 new death per 100 000; -19%), France (900 new deaths; 1.4 new deaths per 100 000; +2%), and Italy (898 new deaths; 1.5 new deaths per 100 000; -11%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 123 000 new weekly cases, a 24% decline as compared to the previous week, continuing the decreasing trend observed since January 2022. However, Timor-Leste and India reported increases in new weekly cases of 57% (11 vs 7 new cases) and 40% (21 643 vs 15 448 new cases), respectively. The highest numbers of new cases were reported from Thailand (96 610 new cases; 138.4 new cases per 100 000; -29%), India (21 643 new cases; 1.6 new cases per 100 000; +40%), and Indonesia (2890 new cases; 1.1 new cases per 100 000; -32%).

New weekly deaths increased by 69% in the Region as compared to the previous week, with over 2600 new deaths reported, mostly due to a delay in reporting of deaths from India. The highest numbers of new deaths were reported from India (1650 new deaths; <1 death per 100 000; +273%), Thailand (842 new deaths; 1.2 new deaths per 100 000; -6%) and Indonesia (173 new deaths; <1 new death per 100 000; -26%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

In the Western Pacific Region, new weekly cases have continued to decline since March 2022. Over 1.1 million new cases were reported, a 20% decrease as compared to the previous week. However, nine (29%) countries in the Region reported an increase of 20% or greater, with some of the largest increases observed in the Solomon Islands (2202 vs 299 new cases; +636%), Fiji (110 vs 22 new cases; +400%) and New Caledonia (96 vs 36 new cases; 167%). The highest numbers of new cases were reported from the Republic of Korea (380 455 new cases; 742.1 new cases per 100 000; -35%), Australia (271 216 new cases; 1063.6 new cases per 100 000; -8%), and Japan (254 946 new cases; 201.6 new cases per 100 000; -11%).

The number of new weekly deaths in the Region shows a decrease of 8% as compared to the previous week, with over 2000 new deaths reported. The highest numbers of new deaths were reported from the Republic of Korea (742 new deaths; 1.4 new deaths per 100 000; -29%), China (416 new deaths; <1 new death per 100 000; +93%), and Japan (283 new deaths; <1 new death per 100 000; -3%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 89, published 27 April 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 24 April 2022

Globally, the number of new COVID-19 cases and deaths has continued to decline since the end of March 2022. During the week of 18 through 24 April 2022, over 4.5 million cases and over 15 000 deaths were reported, decreases of 21% and 20% respectively, as compared to the previous week (Figure 1).

However, not all the Regions have shown a decreasing trend: the number of new weekly cases increased in the Region of the Americas (+9%) and in the African Region (+32%) in the past week, while the number of new weekly deaths increased in the South-East Asia Region (+41%) - due to a delay in reporting of deaths from India - and in the Africa Region (+110%). As of 24 April 2022, over 500 million confirmed cases and over six million deaths have been reported globally.

These trends should be interpreted with caution as several countries have been progressively changing their COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 24 April 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest numbers of new weekly cases were reported from Germany (675 022 new cases; -13%), the Republic of Korea (589 442 new cases; -39%), France (542 896 new cases; -34%), Italy (419 374 new cases; -1%), and the United States of America (298 306 new cases; +21%).

The highest numbers of new weekly deaths were reported from the United States of America (2 354 new deaths; -24%), the Russian Federation (1 402 new deaths; -21%), the Republic of Korea (1 041 new deaths; -38%), Italy (1 007 new deaths; +7%), and the United Kingdom (903 new deaths; -47%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 24 April 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 289 820 (50%)	-23%	213 043 360 (42%)	6 811 (45%)	-23%	1 980 000 (32%)
Western Pacific	1 487 880 (33%)	-28%	53 464 927 (11%)	2 246 (15%)	-33%	222 968 (4%)
Americas	550 015 (12%)	9%	152 533 748 (30%)	4 029 (27%)	-19%	2 719 562 (44%)
South-East Asia	161 639 (4%)	-6%	57 734 555 (11%)	1 580 (10%)	41%	783 530 (13%)
Africa	35 994 (1%)	32%	8 721 105 (2%)	185 (1%)	110%	171 564 (3%)
Eastern Mediterranean	22 878 (1%)	-30%	21 685 928 (4%)	283 (2%)	-34%	342 020 (5%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised as needed to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are encouraged to investigate and report on the impacts of these variants. *When referring to the genomic sequence of SARS-CoV-2 identified from the first cases (December 1) the term 'inde virus' should be used.*

Geographic spread and prevalence of VOCs

The Omicron VOC remains the dominant variant circulating globally. Among the 257 337 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 256 684 (99.7%) were Omicron, 47 (<0.1%) were Delta, and 555 (0.2%) sequences were not assigned to a Pango lineage. While the decrease in sequences is consistent with the overall decreasing trend in new cases reported globally, it may also reflect changes in epidemiological surveillance policies in some countries, including changes in sampling and sequencing strategies. [WHO recommends](#) maintaining strong surveillance for SARS-CoV-2 through the remainder of the acute phase of the pandemic.

Since the emergence of Omicron in November 2021, the virus has continued to evolve, giving rise to many descendent and recombinant lineages. WHO is monitoring the different Omicron descendent lineages under the umbrella of Omicron (VOC). The genetic diversification of Omicron indicates ongoing selection pressure on the virus to adapt to its host and to its environment. Each lineage has additional and/or different mutations. These may or may not lead to amino acid substitutions in relevant genomic sites; the genetic differences may be small and are often related to local geographic genetic drift rather than having additional amino acid substitutions suspected to impact virus phenotype. Currently, the impacts of each single mutation or constellations of mutations are not well known, and thus it is important to continue to monitor for any associated changes in epidemiology. As for any emerging SARS-CoV-2 variant, WHO applies the same criteria for risk assessment apply to descendent and recombinant lineages.

The previously reported upsurge in cases observed in some countries may be due to the higher intrinsic transmissibility and/or higher immune escape properties of the circulating descendent lineages, waning immunity or a combination of these factors in the context of an evolving genetic landscape. To date, and with limited data currently available, there appears to be a growth advantage for BA.4, BA.5 and BA.2.12 over BA.2. Currently, available evidence does not suggest differences in severity or clinical manifestations. More data are expected as studies are ongoing.

ⁱIncludes sequences submitted to [GISAID](#) with sample collected dates from 23 March to 21 April 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 38 countries submitted a total of 100 sequences and above on GISAID.

Characteristics of Omicron

Available evidence on the phenotypic impacts of VOCs has been reported in previous editions of the COVID-19 Weekly Epidemiological Update. Since the last update on 5 April 2022, there have been several new publications on the phenotypic characteristics of VOCs, including literature on Omicron (Table 2). Some of these studies have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Table 2: Summary of current evidence on Omicron

Domain	Indicator	Main results
Epidemiology	Impact on disease prevalence/incidence	<p>Following an increase in the first half of March 2022, the number of new COVID-19 cases has continued to decrease in most countries since the third week of March. There was a 21% decline during the week of 18 through 24 April 2022 as compared to the previous week (WEU 88). It is important to note that recent changes in testing policies may influence the number of reported cases.</p> <p>The Omicron variant is the dominant circulating variant globally, representing over 99.7% of samples collected between 23 March 2022 and 21 April 2022.¹</p>
	Impact on transmission	Analysis of GISAID data ² have consistently shown Omicron (all lineages) having a higher growth rate advantage over Delta in all countries with sufficient sequence data (last update included data available up to 4 April 2022). In this iteration of the analysis, the results were consistent with the previous iteration regarding the growth rate advantage of the Omicron BA.2 descendent lineage over BA.1, with a pooled mean transmission advantage of 72% (95% CI: 55%-82%) under the assumption of an unchanged generation time. These estimates are stabilising as the cumulative number of Omicron sequences is increasing and data become available from more countries. However, an updated analysis will be performed taking into account the various sub-lineages of the Omicron variant that have recently been identified.
	Impact on disease severity	Omicron has consistently been associated with lower severity when compared to Delta across different settings. ³⁻⁶ A recent study conducted in England, United Kingdom, reported lower severity from infection with Omicron compared to infection with Delta. In this study, the adjusted hazard ratio (aHR) for hospitalisation among unvaccinated individuals was 0.41 (95% CI: 0.39-0.43) and the aHR for death was 0.31 (95% CI: 0.26-0.37), which suggests lower intrinsic severity of the Omicron variant. ⁷
Immune response	Impact on reinfection	Higher rates of reinfection have been reported for Omicron as compared to other SARS-CoV-2 variants. However, a protective effect of previous infection was reported in a recent study conducted in the United States of America ⁸ , which found increased antibody titres and neutralisation activity (79.5%) against Omicron among vaccinated solid organ transplant recipients who were previously infected with SARS-CoV-2 infection compared to those who had no previous infection (34%). Previous infection with BA.1 has been suggested as potentially conferring protection against infection with BA.2: 94.9% (95% CI: 88.4-97.8%), and 85.6% (95% CI: 77.4-90.9%) protection against BA.1 following infection with BA.2. ⁹
	Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section 'Interpretation of the results of the VE for the Omicron variant'.
	Impact on antibody responses	Several studies have found lower neutralising antibody titers to BA.1 and BA.2 when compared to the index virus, and similar responses for BA.1 and BA.2. ^{10,11} Similar non-neutralising antibody responses to BA.1 and BA.2 have also been reported in vaccinated individuals (Bartsch 2022). However, another study reported reduced vaccine-induced and infection-induced neutralization of BA.1 and BA.2, with higher neutralisation activity against BA.2 compared to BA.1. ¹² In summary, these results indicate lower humoral responses to BA.1 and BA.2 but inconsistent findings regarding BA.1 versus BA.2.

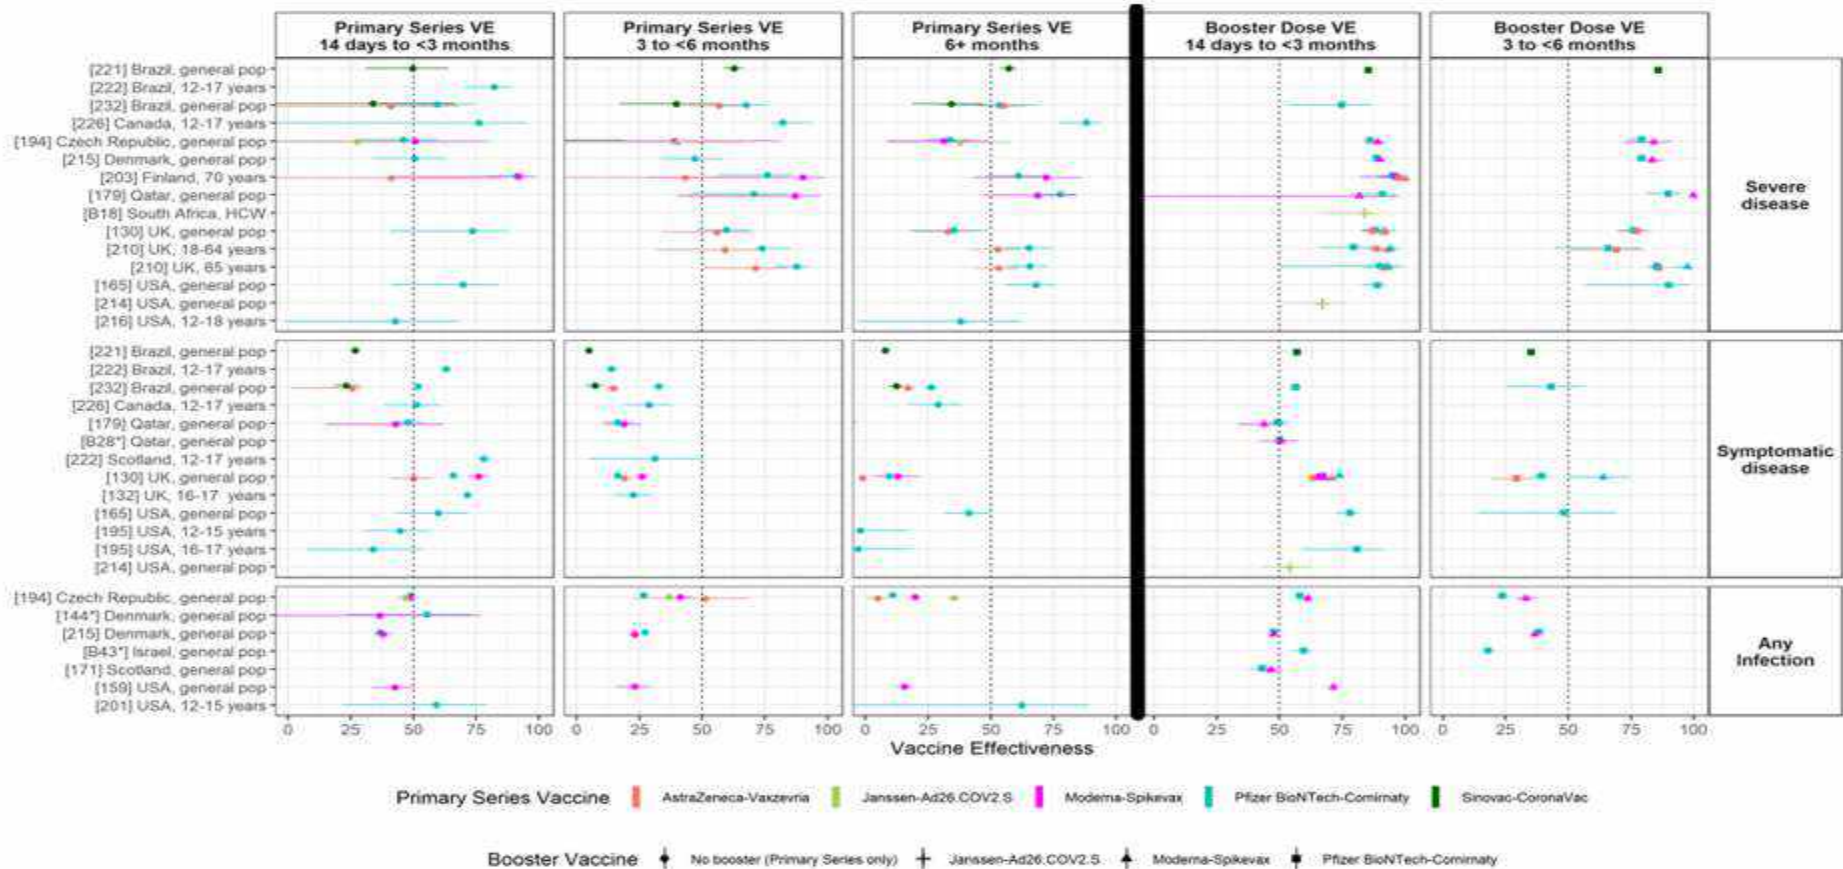

Diagnostic tools	Impact on PCR assays	Most BA.2 sequences lack the 69-70 deletion responsible for S-gene target failure; however, a number of BA.2 sequences have been identified having the 69-70 deletion. ¹ Assessment of PCR tests for SARS-CoV-2 that include multiple gene targets have predicted limited impact of the Omicron variant on the accuracy of these assays. ^{13,14}
	Impact on Rapid Diagnostic tests	A recent study conducted in the United States of America found that the sensitivity of Ag-RDT tests was similar for Omicron, Delta and the index virus. ¹⁵
Impact on treatment	Impact on antivirals	Consistent with preliminary data showing no difference in the effectiveness of antiviral agents against the Omicron variant, a recent review reported similar efficacy of antiviral agents against Omicron and previous SARS-CoV-2 variants. ¹⁶
	Impact on biologicals	Initially, studies on the effectiveness of monoclonal antibodies for treating patients with Omicron reported conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduction in effectiveness of other monoclonal antibodies. ^{12,17–20} However, additional preclinical evidence has shown reduced neutralizing activity of sotrovimab against the BA.2, and lack of efficacy of casirivimab-imdevimab against the BA.1. ²¹
	Other treatment options	There is no evidence available on the effectiveness of interleukin-6 receptor blockers and corticosteroids for the management of severe patients with Omicron.

Figure 4 summarizes the impact of Omicron VOC, on product-specific vaccine effectiveness (VE) over time for both primary series vaccination and booster vaccination. Since the last [update](#), four new studies, one of which assessed VE against Omicron, and three which assessed VE against both Delta and Omicron, have been added to the figure.^{22–26} One study (not yet peer reviewed) provided new VE data on Sinovac-CoronaVac²³, two (both not yet peer-reviewed) on Pfizer BioNTech-Comirnaty^{24,25}, and one (not yet peer reviewed) on AstraZeneca-Vaxzevria, Janssen-Ad26.Cov2.S, Pfizer BioNTech-Comirnaty, and Sinovac-CoronaVac.²⁶ Additional information on vaccine performance against VOCs can also be found in Annex 4.

Figure 4. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

*Indicates booster dose vaccine effectiveness evaluated using persons completing primary series as reference group, rather than unvaccinated persons. Abbreviations: pop=population; HCW=healthcare workers; EU=European Union. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the [summary table](#) of VE effectiveness studies on [view-hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes severe disease, hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, three negative point estimates for the primary series are not shown in the Omicron plot: Moderna-Spikevax VE against symptomatic disease at 6+ months (reference 179) as well as Moderna-Spikevax and Pfizer BioNTech-Comirnaty VE against infection at 3-6 months (reference 144).

Interpretation of the results of the VE for the Omicron variant

To date, 17 studies of VE against the Omicron variant show reduced protection of primary series COVID-19 vaccinations for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for other variants of concern. Importantly though, VE estimates against the Omicron variant remain higher for *severe disease* than for other outcomes in most studies. Booster vaccination substantially improves VE for all outcomes for all products. However, few studies have followed persons for six months or more after booster vaccination to evaluate longer duration of protection.

For *severe disease*, within the first three months of primary series vaccination, six of 11 (55%) VE estimates for the mRNA vaccines were $\geq 70\%$. Three studies for vector vaccines (AstraZeneca-Vaxzevria and Janssen-Ad26.COV2.S) and two studies for inactivated vaccines (Sinovac-CoronaVac) reported VE of $< 50\%$. Beyond three months after vaccination, 10 of 25 (40%) VE estimates for the mRNA vaccines were $\geq 70\%$ while 18 (72%) were $\geq 50\%$, one of the 11 (9%) VE estimates for the adenovector vaccines (AstraZeneca-Vaxzevria and Janssen-Ad26.COV2.S) was $\geq 70\%$ while seven estimates (64%) were $\geq 50\%$, and none of the four (0%) VE estimates for Sinovac-CoronaVac were $\geq 70\%$, while two (50%) were $\geq 50\%$. Between 14 days and three months of receipt of a booster dose, VE against *severe disease* improved in all studies, with only one estimate for Janssen-Ad26.COV2.S below 70% (28 studies evaluated an mRNA booster, three studies a booster dose of Janssen-Ad26.COV2.S, one studies a booster dose of AstraZeneca-Vaxzevria, and two studies a booster dose of Sinovac-CoronaVac). At three to six months post mRNA booster, 12 of 15 (80%) estimates showed VE $\geq 70\%$, including 11 studies in which an mRNA vaccine was given as the primary series, three studies in which AstraZeneca-Vaxzevria was given as the primary series, and one study in which Sinovac-CoronaVac was given as the primary series.

VE estimates against *symptomatic disease* and *infection* within the first three months of primary series vaccination tended to be lower than against *severe disease*, and VE decreased more substantially over time. For *symptomatic disease* within the first three months of primary series vaccination, three of twelve (25%) VE estimates for the mRNA vaccines were $\geq 70\%$; both estimates for AstraZeneca-Vaxzevria and both estimates for Sinovac (CoronaVac) were below 50%. Beyond three months after vaccination, none of the 26 VE estimates were $\geq 50\%$ (18 studies evaluated mRNA vaccines, four evaluated AstraZeneca-Vaxzevria, and four evaluated Sinovac-CoronaVac). Booster vaccination with an mRNA vaccine after completion of a primary series of an mRNA vaccine, AstraZeneca-Vaxzevria, or Sinovac-CoronaVac improved VE against *symptomatic disease*, with four of 14 (29%) VE estimates $\geq 70\%$ and 12 (86%) estimates $\geq 50\%$ between 14 days and three months post booster dose. However, booster dose protection declined with time since vaccination, with only one of six (17%) available estimates indicating a VE of $\geq 50\%$ at three to six months following receipt of an mRNA booster dose. All estimates for a booster dose of Sinovac-CoronaVac (two estimates) or AstraZeneca-Vaxzevria (one estimate) indicated VE $< 50\%$. VE against *infection* showed a similar pattern as that against *symptomatic disease*.

WHO regional overviews:

Epidemiological week 18 – 24 April 2022**

African Region

After a continued decreasing trend in weekly cases since January 2022, the Africa Region reported just under 36 000 new cases and over 185 new deaths, a 32% and a 110% increase respectively as compared to the previous week. Four (18%) countries in the Region reported an increase of over 20% in cases, with some of the greatest proportional increases observed in Burundi (343 vs 103 new cases; +233%), South Africa (19 291 vs 9151 new cases; +111%) and Eswatini (186 vs 132 new cases; +41%). After South Africa, the highest numbers of new cases were reported from Réunion (13 850 new cases; 1546.9 new cases per 100 000; +11%), and Zambia (517 new cases; 2.8 new cases per 100 000; -47%).

The highest numbers of new weekly deaths in the Region were reported from South Africa (154 new deaths; <1 new death per 100 000 population; +221%), Réunion (11 new deaths; 1.2 new deaths per 100 000; similar to the previous week's figures), and Zimbabwe (6 new deaths; <1 new death per 100 000; +20%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas shows an increasing trend after the continued decline observed since January 2022, with over 550 000 new cases reported, a 9% increase as compared to the previous week. Eighteen (32%) countries in the Region reported increases in new cases of 20% or greater, with the largest increases observed in Saint Vincent and the Grenadines (45 vs 9 new cases; +400%), Puerto Rico (21 622 vs 5106; +323%) and Argentina (24 832 vs 6695 new cases; +271%). The highest numbers of new cases were reported from the United States of America (298 306 new cases; 90.1 new cases per 100 000; +21%), Brazil (91 395 new cases; 43.0 new cases per 100 000; -26%), and Canada (63 247 new cases; 167.6 new cases per 100 000; -6%).

The number of new weekly deaths in the Region decreased by 19% as compared to the previous week, with just over 400 new deaths reported. The highest numbers of new deaths were reported from the United States of America (2354 new deaths; <1 new death per 100 000; -24%), Brazil (650 new deaths; <1 new death per 100 000; -17%), and Canada (452 new deaths; 1.2 new deaths per 100 000; +40%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline after reaching a peak in early February 2022. Over 22 000 new weekly cases were reported last week, a 30% decrease as compared to the previous week. Three (14%) countries in the Region have reported increases in new cases of 20% or greater, with the largest proportional increases observed in Sudan (40 vs 23 new cases; +74%) and Libya (42 vs 28 new cases; +50%). The highest numbers of new cases were reported from the Islamic Republic of Iran (10 448 new cases; 12.4 new cases per 100 000; -36%), Bahrain (3071 new cases; 180.5 new cases per 100 000; -8%), and the United Arab Emirates (1628 new cases; 16.5 new cases per 100 000; -6%).

The number of new weekly deaths in the Region decreased by 34% when compared to the previous week, with just 283 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (162 new deaths; <1 new death per 100 000; -27%), Egypt (42 new deaths; <1 new death per 100 000; -14%), and Tunisia (24 new deaths; <1 new death per 100 000; -71%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After the increase observed during the first half of March 2022, new weekly cases continue to decrease in the European Region. Over 2.2 million new cases were reported, a 23% decrease as compared to the previous week. Only one country, Albania, reported an increase in new cases of 21% (329 vs 271 new cases). The highest numbers of new cases were reported from Germany (675 022 new cases; 811.6 new cases per 100 000; -13%), France (542 896 new cases; 834.7 new cases per 100 000; -34%), and Italy (419 374 new cases; 703.2 new cases per 100 000; -1%).

The number of new deaths has continued to decrease in the Region, with just over 6800 new deaths reported this week, a 23% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (1402 new deaths; 1.0 new deaths per 100 000; -21%), Italy (1007 new deaths; 1.7 new deaths per 100 000; +7%), and the United Kingdom (903 new deaths; 1.3 new deaths per 100 000; -47%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 161 000 new weekly cases, a 6% decline as compared to the previous week, continuing the decreasing trend observed since January 2022. However, India reported an increase in new weekly cases of 126% (15 448 vs 6 826 new cases). The highest numbers of new cases were reported from Thailand (135 915 new cases; 194.7 new cases per 100 000; -7%), India (15 448 new cases; 1.1 new cases per 100 000; +126% increase), and Bhutan (4 975 new cases; 644.8 new cases per 100 000; -53%).

New weekly deaths increased by 41% in the Region as compared to the previous week, partly due to a delay in reporting of deaths from India (n= 150 new deaths). The highest numbers of new deaths were reported from Thailand (893 new deaths; 1.3 new deaths per 100 000; +12%), India (442 new deaths; <1 new death per 100 000; +570%), and Indonesia (234 new deaths; <1 new death per 100 000; -3%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

After the increasing trend in new cases observed in the Western Pacific Region between December 2021 and March 2022, new weekly cases declined for a fifth consecutive week (-28% as compared to the previous week), with over 1.4 million new cases reported. However, nine (29%) countries in the Region reported an increase of 20% or greater, with some of the largest increases observed in Samoa (2 702 vs 772 new cases; +250%), Palau (157 vs 52 new cases; +202%), and New Caledonia (72 vs 27 new cases; +167%). The highest numbers of new cases were reported from the Republic of Korea (589 442 new cases; 1149.7 new cases per 100 000; -39%), Australia (294 982 new cases; 1156.8 new cases per 100 000; -11%), and Japan (287 210 new cases; 227.1 new cases per 100 000; -16%).

The number of new weekly deaths shows a decrease of 33% as compared to the previous week, with over 2 200 new deaths reported. The highest numbers of new deaths were reported from the Republic of Korea (1 041 new deaths; 2.0 new deaths per 100 000; -38%), Japan (292 new deaths; <1 new death per 100 000; -16%), and China (215 new deaths; <1 new death per 100 000; -47%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

'Countries' may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 2. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Annex 4 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the Annex 4.

Annex 3. Methods for Figure 4

- Figures include 22 studies from Brazil, Canada, the Czech Republic, Denmark, Finland, Israel, Qatar, South Africa, the United Kingdom, and the United States of America evaluating the VE against the Omicron variant.
- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when either Delta or Omicron was the predominant circulating variant. Estimates were included if they were of laboratory-confirmed cases of the Omicron or Delta variant. In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.
- For the primary series VE, estimates are only included in the plot for studies that report VE for more than one time period.

Annex 4. Summary of Primary Series Vaccine Performance against Variants of Concern (VE data as of 21 April 2022; Neutralization data as of 20 April 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺								Vaccines without WHO EUL ⁺	
	AstraZeneca- Vaxzevria/ SII - Covishield	Beijing CNBG- BBIBP-CorV	Bharat-Covaxin	Janssen- Ad26.COV 2.S	Moderna- mRNA-1273	Novavax- Nuvaxovid/ SII - Covavax	Pfizer BioNTech- Comirnaty	Sinovac- CoronaVac	Anhui ZL- Recombinant	Gamaleya- Sputnik V
Alpha, Beta, Gamma										
Summary of VE*	See update from 11 January 2022 for details of vaccine performance against Alpha, Beta, and Gamma variants of concern									
Delta										
Summary of VE*	See update from 12 April 2022 for details of vaccine performance against Delta variant of concern									
Omicron										
Summary of VE*	Reduced protection against infection and symptomatic disease; possible reduced protection against for severe disease but limited evidence									
- Severe disease	-	-	-	-	↓↓/↓↓ ₁	-	↓↓↓ to ↓↓↓↓ ₄	-	-	-
- Symptomatic disease	↓↓↓ ₁	-	-	-	↓↓↓/↓↓↓ ₂	-	↓↓↓ ₃	-	-	-

Neutralization	↓↓↓ to ↓↓↓↓									
	↓↓↓ ₇	↔ to ↓↓↓ ₃	↓↓↓ ₁	↔ to ↓↓↓ ₄	↓↓↓ ₁₈	-	↓↓↓ ₄₅	5	-	↓↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction²⁷ in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in the study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

COVID-19 Weekly Epidemiological Update

Edition 88, published 20 April 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: Applying Geographic Information Systems to the COVID-19 response](#)
- [WHO regional overviews](#)

Global overview

Data as of 17 April 2022

Globally, the number of new COVID-19 cases and deaths has continued to decline since the end of March 2022. During the week of 11 through 17 April 2022, over 5 million cases and over 18 000 deaths were reported, decreases of 24% and 12% respectively, as compared to the previous week (Figure 1).

All regions reported decreasing trends in the number of new weekly cases and deaths (Table 1). As of 17 April 2022, over 500 million confirmed cases and over 6 million deaths have been reported globally.

These trends should be interpreted with caution as several countries are progressively changing their COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 17 April 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the Republic of Korea (972 082 new cases; -33%), France (827 350 new cases; -11%), Germany (769 466 new cases; -25%), Italy (421 707 new cases; -6%), and Japan (342 665 new cases; +1%).

The highest number of new weekly deaths were reported from the United States of America (3 076 new deaths; -9%), the Russian Federation (1 784 new deaths; -11%), the Republic of Korea (1 671 new deaths; -24%), Germany (1227 new deaths; -27%), and Italy (944 new deaths; -5%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 17 April 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 790 061 (50%)	-25%	210 461 092 (42%)	8 450 (46%)	-23%	1 967 276 (32%)
Western Pacific	2 078 718 (37%)	-28%	51 977 047 (10%)	3 336 (18%)	-25%	220 722 (4%)
Americas	490 525 (9%)	-2%	151 955 885 (30%)	4 797 (26%)	-15%	2 714 852 (44%)
South-East Asia	172 308 (3%)	-16%	57 572 881 (11%)	1 117 (6%)	-18%	781 950 (13%)
Eastern Mediterranean	32 550 (1%)	-26%	21 662 992 (4%)	428 (2%)	-25%	341 737 (6%)
Africa	25 107 (<1%)	-7%	8 682 837 (2%)	87 (<1%)	-16%	171 378 (3%)
Global	5 589 269 (100%)	-24%	502 313 498 (100%)	18 215 (100%)	-21%	6 197 928 (100%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact the effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the lists of currently circulating and previously circulating VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are encouraged to investigate and report on the impacts of these variants. When referring to the genomic sequence of SARS-CoV-2 identified from the first cases (December 2019), the term 'index virus' should be used.

The Omicron variant remains the dominant variant circulating globally, accounting for nearly all sequences recently reported to GISAID. Among the 313 715 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 312 033 (99.5%) were Omicron, 136 (<0.1%) were Delta and 1 393 (0.4%) sequences were not assigned to a Pango lineage.

These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as laboratory turn-around times for sequencing and delays in reporting.

- [VIEW-hub: repository for the most relevant and recent vaccine data](#)
- [WHO Statement on Omicron sublineage BA.2](#)

ⁱIncludes sequences submitted to [GISAID](#) with sample collected dates from 16 March to 14 April 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 42 countries submitted a total of 100 sequences and above on GISAID.

Special Focus: Applying Geographic Information Systems to the COVID-19 response

What is a Geographic Information System?

A Geographic Information System (GIS) is a “collection of computer software and data used to view and manage information about geographic objects, analyse spatial relationships and model spatial processes”.¹ GIS sciences have evolved to integrate the storage of spatial information, spatial and statistical analysis, investment in infrastructure for data acquisition, such as the use of remote sensing and machine learning, incorporating crowdsourcing and big data.² GIS and other geospatial technologies can be used as practical tools for data-driven decision-making in a wide array of disciplines, including public health. GIS has long been utilised in epidemiology, including by John Snow in 1854 to investigate a cholera epidemic in the United Kingdom,³ and continues to be widely utilised today.

How does the use of GIS contribute to health emergency response?

When applied to public health, GIS can analyse the spatial distribution of health outcomes and risk factors, to identify, prevent and control diseases, and improve the impact of health interventions. For example, GIS is easily integrated with demographic data, and can also help achieve equitable vaccine distribution and access to care. GIS also enables the spatial representation of data to support better public health planning and decision-making.

In health emergencies, GIS can support the identification of disease clusters and their possible causes, improve deployment for emergency services, determine if an area is being served adequately by health services, and support operational decision-making in other ways. GIS can also visualise and communicate spatial data intuitively to a wide variety of audiences in a timely manner. The effective use of GIS can strengthen countries’ capacities to detect and respond to health emergencies.

For many years, [WHO and partners have employed GIS](#) to support the response to health emergencies, including outbreaks of Ebola virus disease, polio, measles, Zika virus disease, yellow fever, plague and cholera, as well as natural disasters and humanitarian crises such as famine and armed conflicts. The use of GIS can be adapted depending on the scale of the emergency and the extent of the affected areas. For example, GIS can support a local response by analysing the space-time travel patterns of patients to efficiently allocate available health screening resources, identifying the location of health facilities, and delineating health administrative boundaries to better understand healthcare accessibility in areas where there were previously sparse or inaccurate data. Mapping environmental factors related to disease, such as the distribution of disease-carrying mosquitoes, can inform risk assessments. At a regional or global level, GIS can inform data-driven decision-making by consolidating and presenting the epidemiological situation in multiple countries through GIS dashboards. WHO has drawn upon the knowledge accumulated in past health emergencies to strengthen the COVID-19 response.

How has WHO applied GIS to the COVID-19 pandemic response?

In the early stages of the pandemic, WHO used GIS to guide response activities by creating operational maps presenting data, such as flight patterns and air passenger volume, subnational level locations of reported cases, and laboratory networks of WHO collaborating centres worldwide to show laboratory testing capacity. Some regions also developed interactive dashboards to present the location of alerts (possible COVID-19 cases which required verification). [WHO has also applied GIS to ensure that rural indigenous populations are considered in the COVID-19 response](#) using spatial analyses, geotagging cases and contacts, and coordinating digital microplanning to ensure equitable vaccine access.

As SARS-CoV-2 variants of concern (VOCs) emerged, WHO produced maps to visualise the evolving proportion of VOCs in countries, based on genetic sequences uploaded to [GISAID](#). In the [Weekly Epidemiological Update on COVID-19](#), WHO publishes maps of the weekly case and death incidences. Such maps continue to support high-level decision-making at the World Health Assembly, and by its external advisory groups, including the IHR Emergency Committee on COVID-19. At the regional level, maps regularly contribute to operational decision-making and data visualisation and are included in internal and external information products. Examples of indicators presented in these maps included monthly attack and mortality rates, the evolution of the geographic spread of cases, distribution of VOCs, vaccine coverage, recent trends in the number of new weekly cases, and testing rates.

In addition to the above activities, one of the main applications of GIS in WHO's pandemic response at the global level is visualising and sharing data through public dashboards. WHO launched a global COVID-19 Dashboard in January 2020 to rapidly share daily epidemic situation updates with the number of cases and deaths that were reported by Member States through the International Health Regulations (2005), based on the WHO case definitions (figure 4).

Figure 4. WHO COVID-19 Dashboard showing cases reported globally

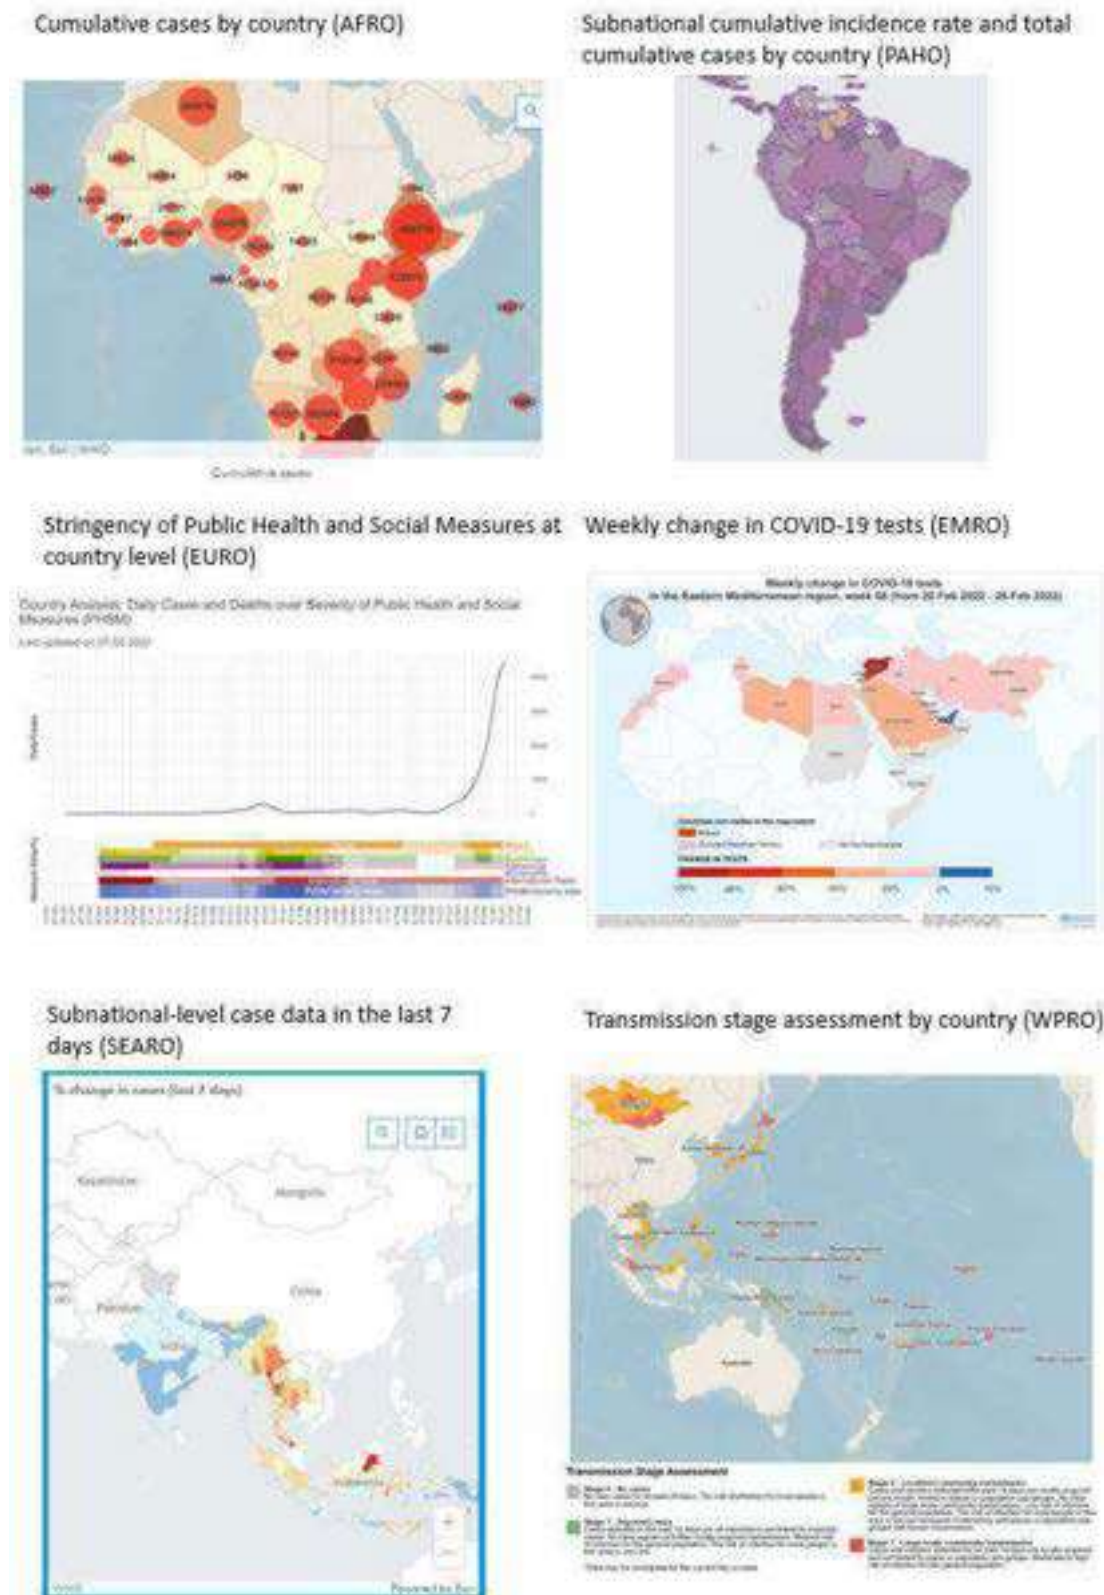

Since then, WHO has added features to the WHO COVID-19 Dashboard in response to evolving needs and interests related to the pandemic. Some examples include the addition of data visualisation for:

- Vaccination, with associated data download functionality, to better understand vaccine delivery and implementation worldwide.
- [Public Health and Social Measures \(PHSM\)](#) and the types of PHSM implemented by countries at any given time.

As of 20 April 2022, the WHO COVID-19 Dashboard has been visited by over 58 million users, with approximately 100 000 daily visitors globally. Additionally, all six WHO Regions host region-specific dashboards which, in some cases, present subnational data, providing a more granular view of COVID-19 epidemiology ([African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), [Western Pacific Region](#)), which can inform risk assessments and provide an enhanced alerting system for local health authorities (figure 5).

Figure 5. Select features of WHO Regional Office COVID-19 dashboards*

AFR: WHO African Region; AMR: WHO Regional of the Americas; EMR: WHO Eastern Mediterranean Region; EURO: WHO European Region; SEARO: WHO South-East Asia Region; WPR: WHO Western Pacific Region

*The images are for demonstration purposes only and do not reflect the latest situation.

Regional response teams apply GIS technology in a multitude of ways, including:

- Developing an urbanism index using remote sensing at the district and regional levels. This index is used to track the impact of COVID-19 and differences in equity between rural and urban areas.
- Transferring technology and skills to national authorities to support the automation of calculating complex COVID-19 indicators.
- Publicly sharing subnational-level data in a format that is readily re-usable by the media, academia, governments and researchers.
- Creating [map animations](#) to show changes in case distribution over time.

Conclusion

Maps can effectively and intuitively visualize information for health professionals and key decision-makers to support a timely response during a health emergency. Data visualisation on dashboards, especially when numbers change rapidly, is an effective way to share data, and has become a standard way to communicate data during the COVID-19 pandemic. The pandemic has posed unique challenges to employing GIS, such as implementing new data management systems to respond to a global event, the requirement for significant investment and expertise to maintain and develop them, and ensuring their ongoing performance despite very large datasets. The response to COVID-19 has highlighted that these systems need to be designed to be adaptable. The content and granularity of data, reporting practices, and epidemiological and social contexts can change as information becomes available at different stages of a pandemic response. GIS is a critical component of response activities to deliver timely and accurate data, information, analysis and visualization to support key public health decision-making for preparedness and response activities.

WHO regional overviews: Epidemiological week 11 – 17 April 2022*

African Region

The African Region has continued to report a decreasing trend in new cases since January 2022, with just over 25 000 new weekly cases reported, representing a 7% decrease as compared to the previous week. However, seven (14%) countries in the Region reported an increase of over 20% in cases, with some of the greatest proportional increases observed in Niger (48 vs 13 new cases; +269%), Mozambique (43 vs 16 new cases; +169%) and Zambia (984 vs 452; +118%). The highest numbers of new cases were reported from Réunion (12 504 new cases; 1396.6 new cases per 100 000 population; +14%), South Africa (9151 new cases; 15.4 new cases per 100 000; similar to previous week figures), and Zambia (984 new cases; 5.4 new cases per 100 000; +118%).

The number of new weekly deaths in the Region decreased by 16% as compared to the previous week, with 87 new deaths reported. The highest numbers of new deaths were reported from South Africa (48 new deaths; <1 new death per 100 000 population; -4%), Réunion (11 new deaths; 1.2 new deaths per 100 000; similar to the previous week), and Zambia (6 new deaths; <1 new death per 100 000 population; similar to the previous week's figures).

Updates from the [African Region](#)

Region of the Americas

With just over half a million new weekly cases and just below 5000 new weekly deaths (representing decreases of 2% and 15% respectively as compared to the previous week), the declining trends observed since mid-January 2022 have continued in the Region of the Americas. However, 13 (23%) countries in the Region reported increases in new cases of 20% or greater, with some of the largest proportional increases observed in Suriname (35 vs 12 new cases; +192%), Haiti (29 vs 11 new cases; +164%) and Saint Lucia (84 vs 51 new cases; +65%). The highest numbers of new cases were reported from the United States of America (245 594 new cases; 74.2 new cases per 100 000; +24%), Brazil (123 339 new cases; 58.0 new cases per 100 000; -17%), and Canada (53 391 new cases; 141.5 new cases per 100 000; -22%).

The highest numbers of new deaths were reported from the United States of America (3076 new deaths; <1 new death per 100 000; -9%), Brazil (785 new deaths; <1 new death per 100 000; -30%), and Chile (234 new deaths; 1.2 new deaths per 100 000; -24%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, the numbers of new weekly cases and deaths continue the decreasing trends observed since early February 2022, with over 32 000 new cases and 428 new deaths reported, representing decreases of 26% and 25% respectively as compared to the previous week. No country in the Region reported increases in new cases of 20% or greater. The highest numbers of new cases were reported from the Islamic Republic of Iran (16 315 new cases; 19.4 new cases per 100 000; -27%), Bahrain (3328 new cases; 195.6 new cases per 100 000; -14%), and Egypt (2800 new cases; 2.7 new cases per 100 000; -28%).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (223 new deaths; <1 new death per 100 000; -26%), Tunisia (84 new deaths; <1 new death per 100 000; -18%), and Egypt (49 new deaths; <1 new death per 100 000; -13%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After the increase observed in mid-March 2022, the number of new weekly cases in the European Region has continued to decline for a month, with just under 2.8 million new cases reported, a 25% decrease as compared to the previous week. However, two countries in the Region reported an increase of over 20% in cases: Kyrgyzstan (10 vs 2 new cases; +400%) and Andorra (381 vs 304 new cases; +25%). The highest numbers of new cases were reported from France (827 350 new cases; 1272.1 new cases per 100 000; -11%), Germany (769 466 new cases; 925.2 new cases per 100 000; -25%), and Italy (421 707 new cases; 707.1 new cases per 100 000; -6%).

The number of new weekly deaths has continued to decrease in the Region, with over 8400 new deaths reported, a 23% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (1784 new deaths; 1.2 new deaths per 100 000; -11%), Germany (1227 new deaths; 1.5 new deaths per 100 000; -27%), and Italy (944 new deaths; 1.6 new deaths per 100 000; -5%).

Updates from the [European Region](#)

South-East Asia Region

In the South-East Asia Region, the numbers of new weekly cases and deaths continue the decreasing trends observed since mid-January 2022, with just over 172 000 new cases and just over 1100 new deaths, decreases of 16% and 18% respectively as compared to the previous week. No country in the Region reported increases in new cases of 20% or greater. The highest numbers of new cases were reported from Thailand (146 474 new cases; 209.8 new cases per 100 000; -15%), Bhutan (10 574 new cases; 1370.4 new cases per 100 000; -2%), and Indonesia (7166 new cases; 2.6 new cases per 100 000; -44%).

The highest numbers of new deaths were reported from Thailand (799 new deaths; 1.1 new deaths per 100 000; + 20%), Indonesia (240 new deaths; <1 new death per 100 000; -29%), and India (66 new deaths; <1 new death per 100 000; -81%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

After the peak reached in early March 2022, the number of new weekly cases has continued to decline in the Western Pacific Region, with just over two million new weekly cases reported, representing a 28% decrease as compared to the previous week. However, Guam and China reported increases of 121% (128 vs 58 new cases) and 28% (28 823 vs 22 519 new cases), respectively. The highest numbers of new cases were reported from the Republic of Korea (972 082 new cases; 1896.0 new cases per 100 000; -33%), Japan (342 665 new cases; 270.9 new cases per 100 000; 1%), and Australia (330 266 new cases; 1295.2 new cases per 100 000; -16%).

The number of new weekly deaths also continues the decreasing trend with over 3300 new deaths reported, a 25% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Republic of Korea (1671 new deaths; 3.3 new deaths per 100 000; -24%), China (405 new deaths; <1 new death per 100 000; -37%), and Japan (346 new deaths; <1 new death per 100 000; -13%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

'Countries' may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purpose.

COVID-19 Weekly Epidemiological Update

Edition 87, published 12 April 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: Update on WHO COVID-19 global rapid risk assessment](#)
- [WHO regional overviews](#)

Global overview

Data as of 10 April 2022

Globally, during the week of 4 through 10 April 2022, the number of new COVID-19 cases and deaths has continued to decline for a third consecutive week, with over 7 million cases and over 22 000 deaths reported, a decrease of 24% and 18% respectively, as compared to the previous week (Figure 1).

All regions reported decreasing trends in the number of new weekly cases and deaths (Table 1). As of 10 April 2022, over 496 million confirmed cases and over 6 million deaths have been reported globally.

These trends should be interpreted with caution as several countries are progressively changing their COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 10 April 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest numbers of new weekly cases were reported from the Republic of Korea (1 459 454 new cases; -29%), Germany (1 019 649 new cases; -26%), France (927 073 new cases; -3%), Viet Nam (453 647 new cases; -43%), and Italy (447 322 new cases; -8%).

The highest numbers of new weekly deaths were reported from the United States of America (3 682 new deaths; -9%), Republic of Korea (2 186 new deaths; -6%), the Russian Federation (2 008 new deaths; -15%), Germany (1 686 new deaths; +6%), and Brazil (1 120 new deaths; -22%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 10 April 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	3 554 764 (49%)	-26%	207 509 074 (42%)	9 920 (44%)	-16%	1 957 395 (32%)
Western Pacific	2 879 100 (40%)	-26%	49 898 300 (10%)	4 431 (20%)	-21%	217 386 (4%)
Americas	516 017 (7%)	-4%	151 456 460 (31%)	5 980 (27%)	-19%	2 709 204 (44%)
South-East Asia	204 527 (3%)	-8%	57 400 374 (12%)	1 358 (6%)	-15%	780 833 (13%)
Eastern Mediterranean	43 920 (1%)	-4%	21 630 352 (4%)	565 (3%)	-18%	341 304 (6%)
Africa	23 323 (<1%)	-17%	8 612 215 (2%)	82 (<1%)	-40%	171 219 (3%)
Global	7 221 651 (100%)	-24%	496 507 539 (100%)	22 336 (100%)	-18%	6 177 354 (100%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are encouraged to investigate and report on the impacts of these variants. When referring to the genomic sequence of SARS-CoV-2 identified from the first cases (December 2019), the term 'index virus' should be used.

Geographic spread and prevalence of VOCs

The Omicron variant remains the dominant variant circulating globally, accounting for nearly all sequences recently reported to GISAID. Among the 379 278 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 376 082 (99.2%) were Omicron, 125 (<0.1%) were Delta and 2 961 (0.8%) sequences were not assigned to a Pango lineage. These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as laboratory turn-around times for sequencing and delays in reporting.

Omicron VOC

WHO continues to monitor several descendent lineages under the Omicron VOC, including BA.1, BA.2, BA.3 as well as now BA.4 and BA.5. It also includes BA.1/BA.2 circulating recombinant forms, such as XE. The full list can be found here https://cov-lineages.org/lineage_list.html

A small number of sequences of BA.4 and BA.5 descendent lineages have now been detected in a few countries. Both have additional mutations in the Spike region (S:L452R, S:F486V) and unique mutations outside of Spike. The S:L452R and S:F486V mutations are associated with potential immune escape characteristics. In addition, the majority of BA.4 and BA.5 sequences have the 69-70 deletion responsible for S gene target failure (SGTF) in some PCR assays. This may prove useful for surveillance purposes in places where BA.2 is dominant, as the 69-70 deletion is largely not present in BA.2 sequences.

WHO is working with scientists to further assess the characteristics of these lineages and their public health implications. WHO recommends countries to continue surveillance, where possible, and rapid data sharing on publicly available databases.

ⁱIncludes sequences submitted to [GISAID](#) with sample collected dates from 9 March to 7 April 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 42 countries submitted a total of 100 sequences and above on GISAID.

Special Focus: Update on WHO COVID-19 global rapid risk assessment

The COVID-19 pandemic continues to evolve, as does our understanding of the SARS-CoV-2 virus, and the response needed to control its spread and impact. In WHO's most recent rapid risk assessment, which was completed on 6 April 2021, the global public health risk was assessed to remain very high due to the ongoing risks to human health, risk of spread and risk of insufficient control capacities.

Under the [Emergency Response Framework](#), WHO undertakes risk assessments and situation analyses on a regular basis to inform its response to emerging situations. In addition, WHO periodically reviews the current risk status of public health events through an in-depth hazard, exposure and context assessment. This also includes a review of the vulnerabilities and capacities available to respond to the public health event and to investigate the current risk to human health, risks of ongoing spread globally, and risk of insufficient control capacities. Such assessments are used as an internal WHO decision-making tool, and to support independent deliberations, including but not limited to meetings of the [International Health Regulations \(IHR 2005\) Emergency Committee regarding the COVID-19 pandemic](#).

To date, 13 global rapid risk assessments have been undertaken for COVID-19, and additional assessments have been conducted for specific events, such as the emergence of SARS-CoV-2 variants. Here, we provide a synopsis of the most recent in-depth global rapid risk assessment for COVID-19.

Despite a reduction in SARS-CoV-2 testing observed since the beginning of 2022 in many Member States, the COVID-19 pandemic continues with intense transmission and high levels of death primarily among unvaccinated at-risk populations. The highly transmissible Omicron variant of concern has rapidly replaced all other circulating variants in almost all countries in which it has been reported, and has become dominant globally.

Omicron's properties of immune escape have been associated with the rapid and almost synchronous increase in the global incidence of COVID-19 cases reported until the end of January 2022. A further increase observed at the beginning of March was driven primarily by a delayed increase in case incidence in the Western Pacific Region and a rebound in the number of new cases reported in the European Region. This trend was likely due to a combination of factors, including the predominance of the Omicron Pango lineages BA.1, and then BA.2, with a transmission advantage over other Omicron lineages; relaxation of public health and social measures (PHSM); and waning of humoral immunity following vaccination and/or prior infection. The recent detection of emerging recombinants of the Delta-Omicron and Omicron descendent lineages requires ongoing close monitoring.

Unlike previous waves, the most recent wave due to Omicron can be characterized by a decoupling between the number of cases, hospitalizations (particularly for intensive care) and deaths in many countries. However, data continue to show that those who are unvaccinated remain at higher risk of severe disease following infection with Omicron as compared to those who have been vaccinated. Despite the reduction in severity, the massive increases

in cases with Omicron have led to large numbers of hospitalizations, putting further pressure on healthcare systems, and in some countries, similar or higher numbers of deaths when compared to previous peaks.

While vaccine effectiveness (VE) wanes against Omicron for all disease outcomes as compared to other VOCs following the primary vaccination series, VE estimates for Omicron remain the highest for severe disease. Furthermore, there is evidence that a booster dose substantially improves VE for all outcomes; however, more data are needed to characterize the duration of this protection.

Over 11 billion vaccine doses have been distributed globally. Nevertheless, substantial inequities remain, with only 11% of those in low-income countries (LICs) having completed the primary series; and major differences among regions, with vaccination coverage ranging from 82% in the Western Pacific Region to 13% in the African Region. There is particular concern about reaching the most vulnerable populations who remain unvaccinated, particularly those of older age and those with comorbidities. Globally, an estimated 35% of those aged 60 years and over are awaiting completion of the primary vaccination series. Despite low vaccination coverage in the African Region, the most recent estimates of combined seroprevalence (vaccine and infection-derived humoral immune response) were 72.6% (95% CI: 71.7-73.5%). Considering the low vaccine coverage, such seroprevalence estimates highlight the extent of SARS-CoV-2 transmission across the Region.

WHO Emergency Use Listing (EUL) approved diagnostic tests, including nucleic acid amplification tests (e.g. polymerase chain reaction (PCR) assays) with more than one viral target or antigen-detection rapid diagnostic tests (Ag-RDTs), remain effective at detecting Omicron infection, including BA.1 and BA.2. WHO is concerned that during recent months, some countries have significantly reduced SARS-CoV-2 testing, despite widespread availability of diagnostic tests. Unless robust surveillance systems are retained, countries may lose the ability to accurately interpret epidemiological trends, implement the appropriate measures necessary to reduce transmission and monitor and assess the evolution of the virus.

Despite current high rates of transmission of SARS-CoV-2, many countries have dropped most PHSM without following a layered or staged approach to relaxation. This can lead to the erosion of public trust and PHSM may not be easily re-implemented should the future need arise, for example following the emergence of a new VOC.

Each country faces different circumstances based on the epidemiological situation and the context. WHO has published an updated [Strategic Preparedness, Readiness and Response Plan to End the Global COVID-19 Emergency in 2022](#) which outlines future scenarios of COVID-19 and how the current strategy needs to be adjusted taking into account the difficulties posed by the pandemic in the light of the many other public health and global challenges. This is particularly apparent during other emergencies including the war in Ukraine and protracted conflicts in many other countries.

The confidence in the available information on the global public health risk remains moderate. There are still gaps in knowledge about the phenotypic impact of emerging SARS-CoV-2 variants and recombinants; the long-term duration of infection and vaccine-derived protection, particularly against severe disease and hospitalization; and the impact of lifting and changing PHSM on transmission, hospitalization and mortality.

WHO regional overviews: Epidemiological week 4 – 10 April 2022*

African Region

The African Region has continued to report a decreasing trend in new cases since January 2022, with just under 23 000 new weekly cases reported, representing a 17% decrease as compared to the previous week. However, seven (14%) countries in the Region reported an increase of over 20% in cases, with some of the greatest proportional increases observed in Lesotho (58 vs 15 new cases; +287%), Mali (53 vs 23 new cases; +130%) and Mayotte (67 vs 52 new cases; +29%). The highest numbers of new cases were reported from Réunion (10 996 new cases; 1228.2 new cases per 100 000 population; +13%), South Africa (9182 new cases; 15.5 new cases per 100 000; -6%), and Seychelles (510 new cases; 518.6 new cases per 100 000; -1%).

The number of new weekly deaths in the Region decreased by 40% as compared to the previous week, with over 80 new deaths reported. The highest numbers of new deaths were reported from South Africa (50 new deaths; <1 new death per 100 000 population; -38%), Réunion (11 new deaths; 1.2 new deaths per 100 000; +57%), and Zimbabwe (11 new deaths; <1 new deaths per 100 000; +22%).

Updates from the [African Region](#)

Region of the Americas

With just over half a million new weekly cases and just below 6000 new weekly deaths (representing decreases of 4% and 19% respectively as compared to the previous week), the decreasing trend observed since mid-January 2022 has continued in the Region of the Americas. However, twelve (21%) countries in the Region reported increases in new cases of 20% or greater, including the United States Virgin Islands (108 vs 45 new cases; +140%), Sint Maarten (89 vs 41 new cases; +117%), Puerto Rico (4236 vs 2396 new cases; +77%) and Argentina (22468 vs 12894 new cases; +74%). The highest numbers of new cases were reported from the United States of America (208 732 new cases; 63.1 new cases per 100 000; +4%), Brazil (148 798 new cases; 70.0 new cases per 100 000; -14%), and Canada (60 099 new cases; 159.2 new cases per 100 000; +7%).

The highest numbers of new deaths were reported from the United States of America (3682 new deaths; 1.1 new deaths per 100 000; -9%), Brazil (1120 new deaths; <1 new death per 100 000; -22%), and Chile (308 new deaths; 1.6 new deaths per 100 000; -21%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline since early February 2022. Just under 44 000 new weekly cases were reported last week, a 4% decrease as compared to the previous week. However, three (14%) countries in the Region have reported increases in new cases of 20% or greater, with the largest observed in the occupied Palestinian territory (537 vs 282 new cases; +90%) and the Islamic Republic of Iran (22378 vs 17582; +27%). The highest numbers of new cases were reported from the Islamic Republic of Iran (22 378 new cases; 26.6 new cases per 100 000; +27%), Egypt (3913 new cases; 3.8 new cases per 100 000; -11%), and Bahrain (3871 new cases; 227.5 new cases per 100 000; -26%).

The number of new weekly deaths in the Region decreased by 18% when compared to the previous week, with over 550 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (300 new deaths; <1 new death per 100 000; -2%), Tunisia (102 new deaths; <1 new death per 100 000; -35%), and Egypt (56 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [Eastern Mediterranean Region](#)

European Region

In the European Region, new weekly cases have continued to decline for a third consecutive week after the increase observed in mid-March 2022, with over 3.5 million new cases reported, a 26% decrease as compared to the previous week. None of the countries in the Region reported increases in new cases of 20% or greater. The highest numbers of new cases were reported from Germany (1 019 649 new cases; 1226.0 new cases per 100 000; -26%), France (927 073 new cases; 1425.4 new cases per 100 000; -3%), and Italy (447 322 new cases; 750.0 new cases per 100 000; -8%).

Also the number of new weekly deaths has continued to decrease in the Region, with over 9900 new deaths reported, a 16% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (2008 new deaths; 1.4 new deaths per 100 000; -15%), Germany (1686 new deaths; 2.0 new deaths per 100 000; +6%), and the United Kingdom (1026 new deaths; 1.5 new deaths per 100 000; -35%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 204 000 new weekly cases, an 8% decline as compared to the previous week, continuing the decreasing trend observed since mid-January 2022. However, Bhutan reported an increase in new weekly cases of 70% (10785 vs 6357 new cases). The highest numbers of new cases were reported from Thailand (171 890 new cases; 246.3 new cases per 100 000; -6%), Indonesia (12 726 new cases; 4.7 new cases per 100 000; -39%), and Bhutan (10 785 new cases; 1397.7 new cases per 100 000; +70%).

The Region reported just over 1300 new weekly deaths, representing a 15% decrease as compared to the previous week. The highest numbers of new deaths were reported from Thailand (668 new deaths; 1.0 new deaths per 100 000; +8%), India (340 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Indonesia (338 new deaths; <1 new death per 100 000; -45%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

After the peak reached in early March 2022, cases have continued to decline in the Western Pacific Region, with over 2.8 million new weekly cases reported, representing a 26% decrease as compared to the previous week. However, five (16%) countries in the Region reported an increase of 20% or greater, with some of the largest increases observed American Samoa (1208 vs 600 new cases; +101%), Samoa (1607 vs 917 new cases; +75%) and Fiji (67 vs 39 new cases; +72%). The highest numbers of new cases were reported from the Republic of Korea (1 459 454 new cases; 2846.6 new cases per 100 000; -29%), Viet Nam (453 647 new cases; 466.1 new cases per 100 000; -43%), and Australia (392 569 new cases; 1539.5 new cases per 100 000; -2%).

The number of new weekly deaths shows a decrease of 21% as compared to the previous week, with just under 4400 new deaths reported. The highest numbers of new deaths were reported from the Republic of Korea (2186 new deaths; 4.3 new deaths per 100 000; -6%), China (645 new deaths; <1 new death per 100 000; -33%), and the Philippines (406 new deaths; <1 new death per 100 000; -8%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

'Countries' may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purpose.

COVID-19 Weekly Epidemiological Update

Edition 86, published 5 April 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 3 April 2022

After the increase observed during the first half of March 2022, the number of new COVID-19 cases has decreased for a second consecutive week, with a 16% decline during the week of 28 March through 3 April 2022 as compared to the previous week (Figure 1). The number of new weekly deaths also decreased sharply (-43%) as compared to the previous week, when an artificial spike in deaths was observed ([see WEU 85](#)).

Across the six WHO regions, over nine million new cases and over 26 000 new deaths were reported. All regions reported decreasing trends both in the number of new weekly cases and new weekly deaths (Table 1). As of 3 April 2022, just over 489 million cases and over 6 million deaths have been reported globally.

These trends should be interpreted with caution as several countries are progressively changing their COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 3 April 2022**

**See [Annex 1: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the Republic of Korea (2 058 375 new cases; -16%), Germany (1 371 270 new cases; -13%), France (959 084 new cases; +13%), Viet Nam (796 725 new cases; -29%), and Italy (486 695 new cases; -3%).

The highest number of new weekly deaths were reported from the United States of America (4 435 new deaths; -10%), the Russian Federation (2 357 new deaths; -18%), the Republic of Korea (2 336 new deaths; -5%), Germany (1 592 new deaths; +5%), and Brazil (1 436 new deaths; -19%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 3 April 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	4 633 407 (50%)	-16%	203 782 791 (42%)	10 448 (40%)	-15%	1 943 512 (32%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health.

The classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are encouraged to investigate and report on the impacts of these variants. When referring to the genomic sequence of SARS-CoV-2 identified from the first cases (December 2019), the term 'index virus' should be used.

Geographic spread and prevalence of VOCs

The Omicron variant remains the dominant variant circulating globally, accounting for nearly all sequences recently reported to GISAID. Among the 417 147 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 416 175 (99.8%) were Omicron, 141 (<0.1%) were Delta, and 562 sequences were not assigned to a Pango lineage (<0.2%). The total number of submitted Omicron sequences continues to decline, a trend observed for each of the Omicron descendent variants. Among the Omicron descendent lineages, the relative proportion of BA.2 has increased to 93.6%, while BA.1.1 accounts for 4.8% and BA.1 and BA.3 account for <0.1% (figure 4, panels A and B) of all Omicron lineages. BA.2 has become dominant in all six WHO regions (figure 4, panel C) and in 68 countries for which sequence data are available. However, there have been subregional differences in the rise of BA.2; notably in South America: BA.2 began to rise later and at a slower rate as compared to other subregions, accounting for 28% of Omicron lineages in week 11 (14 to 20 March 2022). These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as laboratory turn-around times for sequencing and delays in reporting.

Figure 4. Global distribution and relative proportion of Omicron lineages for sequences submitted to GISAID presented by week of specimen collection

Panel A. Relative proportions of Omicron lineages over the last four weeks by week of specimen collection

Lineage	Countries	Sequences ^a	Overall (%)		Last 4 weeks by collection date (%)			
			SGTF ^b	Total	2022-10	2022-11	2022-12	2022-13
BA.1	174	1 124 247	95.93	39.56	5.51	3.18	1.57	0.94
BA.1.1	155	1 017 287	95.35	35.79	17.47	10.99	4.54	4.81
BA.2	114	693 654	0.24	24.41	76.56	85.38	93.44	93.63

^c Median number of days from specimen collection to sequence deposition in GISAID

Reduced number of SARS-CoV-2 sequences in publicly available database

Since the first epidemiological week of 2022, when the highest number of weekly sequences was reported in GISAID (284 061 sequences), the number of weekly sequences has declined progressively. During week 12 (21 to 27 March 2022), only 65 381 sequences were collected and submitted to GISAID. There has been an average of 12% reduction in the weekly collection and submission of sequences. While the decrease in sequences is consistent with the overall trend in new cases observed globally, it may also reflect changes in epidemiological surveillance policies in some countries, including changes in sampling and sequencing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected.

Recombinants update

The SARS-CoV-2 virus continues to evolve. Given the current high level of transmission worldwide, it is likely that further variants, including recombinants, will continue to emerge. Recombination is common among coronaviruses and is regarded as an expected mutational event.

WHO is tracking recombinant variants, both recombinants of Delta (AY.4) and Omicron (BA.1) (e.g., XD Pango lineage), as well as recombinants of BA.1 and BA.2 (e.g., XE Pango lineage). The XD recombinant is being tracked as a VUM by WHO, although its spread appears to have remained limited at present (26 sequences in GISAID). Currently available evidence does not suggest that it is more transmissible than other circulating variants. The XE recombinant is being tracked as part of the Omicron variant. This recombinant was first detected in the United Kingdom on 19 January and approximately 600 sequences have been reported and confirmed as of 29 March 2022. Early estimates suggest that XE has a community growth rate advantage of 1.1 (which represents a 10% transmission advantage) as compared to BA.2; however, this finding requires further confirmation.

The evolution rate and the risk of the emergence of new variants, including recombinants, is still very high. The implementation of continuous, comprehensive and representative community sampling and sequencing strategies, alongside timely sharing of data by Member States, remain critical for tracking and understanding the behaviour of SARS-CoV-2 (see [WEU 85](#)). WHO continues to closely monitor and assess the public health risk associated with recombinant variants, alongside other SARS-CoV-2 variants, and will provide updates as further evidence becomes available.

Characteristics of Omicron

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last update on 22 March 2022](#), there have been several new publications on the phenotypic characteristics of VOCs, including literature on Omicron (Table 2). Some of these studies have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Table 2: Summary of current evidence on Omicron

Domain	Indicator	Main results
Epidemiology	Impact on disease prevalence/incidence	Following an increase in the first half of March 2022, the number of new COVID-19 cases has decreased for a second consecutive week, with a 16% decline during the week of 28 March through 3 April 2022 as compared to the previous week. It is important to note that recent changes in testing policies may influence the number of reported cases. The Omicron variant is the dominant circulating variant globally, representing 99.8% of samples collected between 2 and 31 March 2022 (GISAID), while the Delta variant represents <0.1%. Among the Omicron Pango lineages, BA.2 is the most prevalent (93.6%), followed by BA.1.1 (4.8%), BA.1 and BA.3 account for <0.1%.
	Impact on transmission	In an updated analysis of GISAID data ¹ , Omicron continues to show a growth advantage over Delta in 67 countries with sufficient sequence data available up to 4 April 2022, translating to a pooled mean transmission advantage (i.e., relative difference in effective reproduction numbers) of 110% (95% CI: 90%-131%) across epidemiological contexts, under the assumption of an unchanged generation time (i.e., duration between the moment a person gets infected to the moment they infect another person). However, evidence for a reduced generation time of Omicron suggests the transmission advantage may be lower; for a 20% shorter generation time, the estimated pooled mean transmission advantage of Omicron over Delta is 91% (95% CI: 71%-112%). The same analysis yielded identical results to the previous iteration regarding the growth rate advantage of the Omicron Pango lineage BA.2 over the Pango lineage BA.1, with a pooled mean transmission advantage of 72% (95% CI: 55%-82%), under the assumption of an unchanged generation time. These estimates are stabilising as the cumulative number of Omicron sequences is increasing and data become available from more countries. An updated analysis published on 25 March 2022 by the United Kingdom Health Security Agency ² , which used data on samples collected between 15 December 2021 and 15 March 2022, supports BA.2 as having a higher growth rate compared to BA.1 (median: 75.3% per week).
	Impact on disease severity	Omicron has consistently been associated with lower severity when compared to Delta across different settings. ³⁻⁶ Although reported hospitalisation rates among children 0-4 years in the United States of America were about five times higher during periods of Omicron predominance compared to Delta predominance (14.5 vs. 2.9 per 100,000), length of hospital stay was shorter (2 vs 1.5 days, p = 0.002) and the proportion of children requiring ICU admissions was lower (27% vs 21%, p = 0.02) during Omicron predominance. ⁷ An updated analysis found no difference in the risk of hospitalisation between individuals infected with BA.1 compared to BA.2 (HR=0.94; 95% CI: 0.88-1.0) in the United Kingdom. ²
Immune response	Impact on reinfection	Higher rates of reinfection have been reported for Omicron as compared to other SARS-CoV-2 variants. Reinfection with BA.2 following BA.1 has been associated with mild disease in Denmark ⁸ while in Qatar, previous infection with one of the Omicron Pango lineages was found to potentially confer protection against infection with other Omicron Pango lineages: 94.9% (95% CI: 88.4-97.8%) protection against BA.2 following infection with BA.1, and 85.6% (95% CI: 77.4-90.9%) protection against BA.1 following infection with BA.2. ⁹

Domain	Indicator	Main results
	Impact on vaccination	Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant.
	Impact on antibody responses	There are no new data on antibody responses to Omicron since the epidemiological update published on 22 March 2022 . An analysis of neutralization data from 23 laboratories found a 20-fold reduction in neutralization associated with the Omicron variant. ¹⁰ These findings are consistent with results of recent studies that reported lower neutralising antibody titers to BA.1 and BA.2 compared to wild-type SARS-CoV-2 and similar responses for BA.1 and BA.2. ^{11,12} Another recent study found similar non-neutralising antibody responses to BA.1 and BA.2 in vaccinated individuals. ¹³ Overall, these results indicate similar humoral responses among BA.1 and BA.2.
Diagnostic tools	Impact on PCR assays	Most BA.2 sequences lack the 69-70 deletion responsible for S-gene target failure, with only a limited number of sequences (0.24% out of 693 654) having the 69-70 deletion (GISAID). Assessment of PCR tests for SARS-CoV-2 that include multiple gene targets predicted limited impact of the Omicron variant on the accuracy of these assays. ^{14,15}
	Impact on Rapid Diagnostic tests	Based on evidence from a recent study conducted in the United States of America, the sensitivity of Ag-RDT tests to detect Omicron compared to Delta and wild-type SARS-CoV-2 is similar. ¹⁶
Impact on treatment	Impact on antivirals	Consistent with preliminary data showing no difference in the effectiveness of antiviral agents against the Omicron variant, a recent review reported similar efficacy of antiviral agents against Omicron and previous SARS-CoV-2 variants. ¹⁷
	Impact on biologicals	Initially, studies on the effectiveness of monoclonal antibodies for treating patients with Omicron reported conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduction in effectiveness of other monoclonal antibodies. ^{18–21} However, additional preclinical evidence shows reduced neutralizing activity of sotrovimab against the BA.2 Pango lineage and lack of efficacy of casirivimab-imdevimab against the BA.1 Omicron Pango lineage. ²²
	Other treatment options	There is no evidence available on the effectiveness of Interleukin-6 receptor blockers and corticosteroids for the management of severe patients with Omicron.

Figure 5. Vaccine effectiveness (VE) of primary series and booster vaccination against the Delta variant of concern

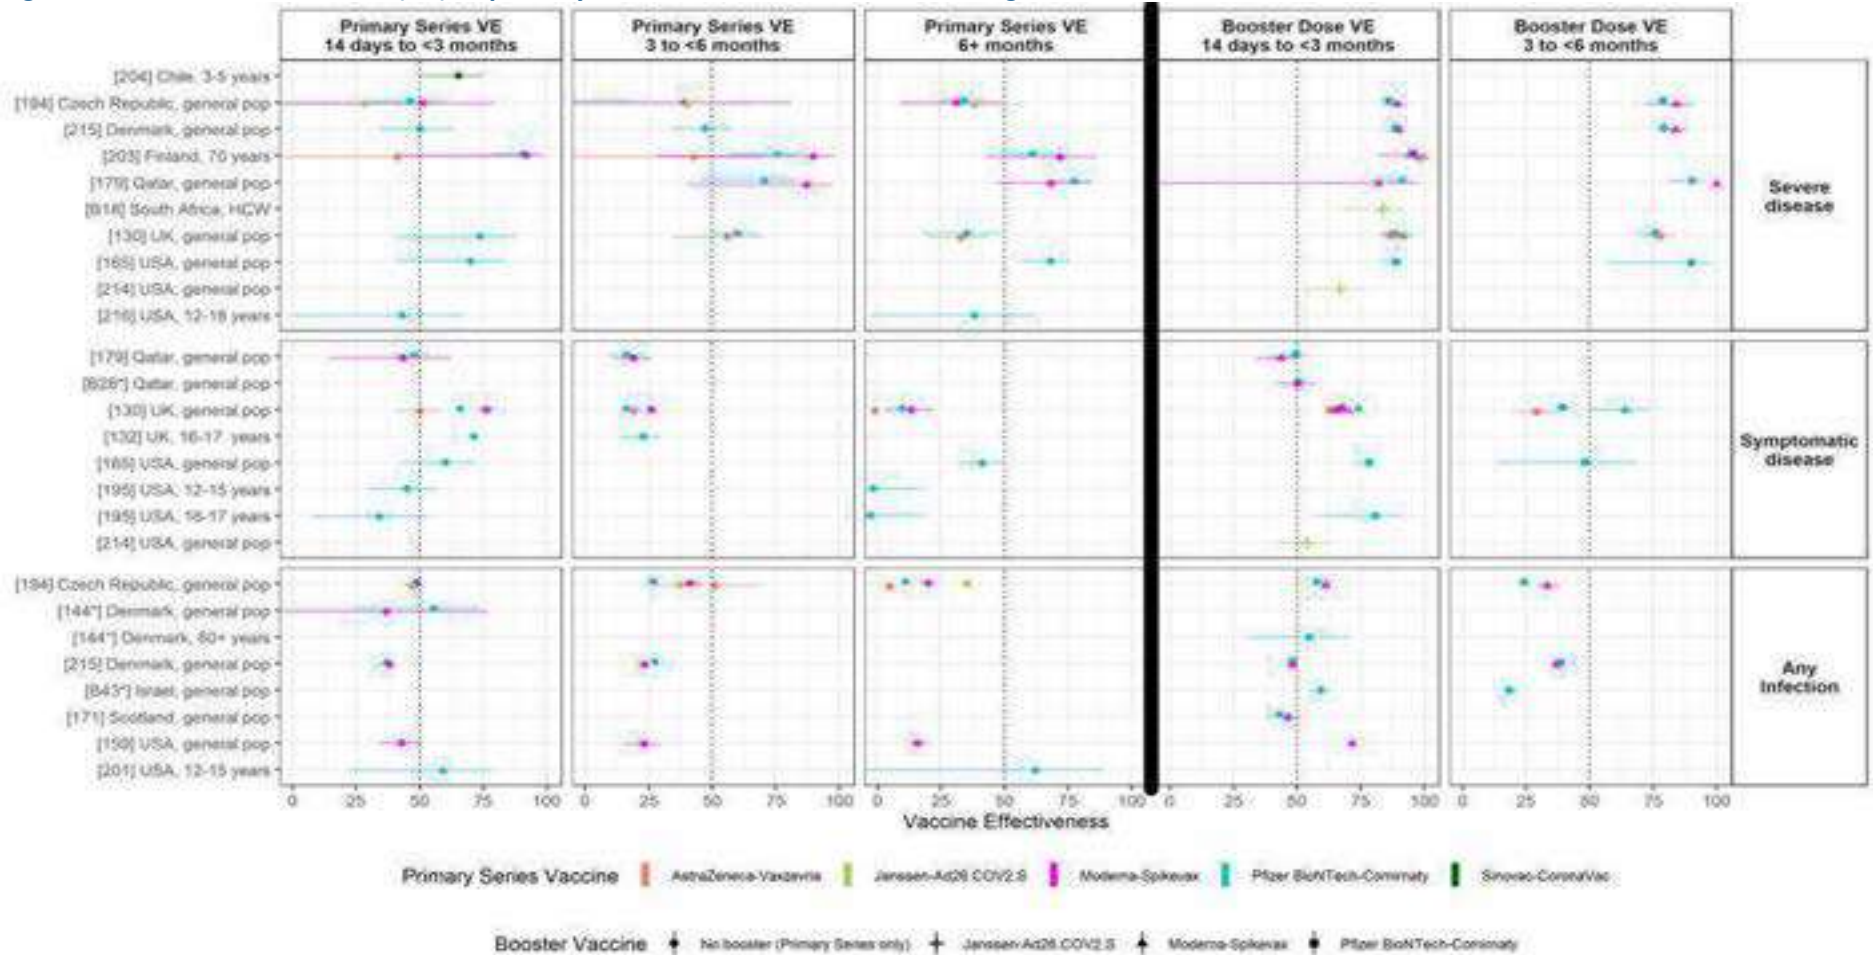

Figure 6. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

*Reference group is fully vaccinated with two doses.

*Indicates booster dose vaccine effectiveness evaluated using persons completing primary series as reference group, rather than unvaccinated persons. Abbreviations: pop=population; HCW=healthcare workers; EU=European Union. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the [summary table](#) of VE effectiveness studies on [view-hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes severe disease, hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, three negative point estimates for the primary series are not shown in the Omicron plot: Moderna-Spikevax VE against symptomatic disease at 6+ months (reference 179) as well as Moderna-Spikevax and Pfizer BioNTech-Comirnaty VE against infection at 3-6 months (reference 144); one negative point estimate for primary series is not shown in the Delta plot: AstraZeneca-Vaxzevria VE against Delta symptomatic disease (reference 112) with 95% CIs crossing 0 is not fully visible in the plot.

Figures 5 and 6 summarize the impact of Delta and Omicron variants, respectively, on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Since the last [update](#), four new studies, one of which assessed VE against Delta, two of which assessed VE against Omicron, and one which also assessed VE against both Delta and Omicron, have been added to the figures.^{23–26} Of the studies on Omicron, one peer-reviewed study provided new VE data on Janssen-Ad26.COVS²³, one (not yet peer-reviewed) on Moderna-Spikevax²⁴, and two (one not yet peer-reviewed) on Pfizer BioNTech-Comirnaty.^{24,26} Additional information on vaccine performance against VOCs can also be found in Annex 4.

Interpretation of the results of the VE for the Omicron variant

To date, twelve studies reporting VE estimates against the Omicron variant show reduced protection of the primary series COVID-19 vaccines for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for other VOCs. Importantly, VE estimates against the Omicron variant remain highest for *severe disease*. Booster vaccination substantially improves VE for all outcomes for all vaccine products. However, due to the short follow-up time, more data are needed to characterize the duration of VE following a booster dose for all outcomes.

For protection against *severe disease*, within the first three months of primary series vaccination, four of eight (50%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty) were $\geq 70\%$; while only two VE were available for vector vaccines (AstraZeneca-Vaxzevria and Janssen-Ad26.COVS), both of which reported a VE of $< 50\%$. Beyond three months after the primary series vaccination, six of 17 (35%) VE estimates for the mRNA vaccines and none of the five available VE estimates for the vector vaccines were $\geq 70\%$. A booster dose improved VE against *severe disease* in all 12 studies, with only one estimate for Janssen-Ad26.COVS being $< 70\%$ between 14 days and three months of receipt of a booster dose (17 VE estimates evaluated an mRNA booster dose and two estimates evaluated a booster dose of Janssen-Ad26.COVS). At three to six months post mRNA booster dose, all nine available estimates showed VE $\geq 70\%$, including six studies in which an mRNA vaccine was given as the primary series and three studies in which AstraZeneca-Vaxzevria was given as the primary series.

Initial VE estimates against *symptomatic disease* and *infection* tended to be lower than against *severe disease*, and VE decreased more substantially over time. For *symptomatic disease* within the first three months of primary series vaccination, two of eight (25%) VE estimates for the mRNA vaccines were $\geq 70\%$, and the single VE estimate for the AstraZeneca-Vaxzevria was $< 70\%$. Beyond three months after vaccination, none of the 14 VE estimates were $\geq 50\%$ (12 estimates evaluated mRNA vaccines and two evaluated AstraZeneca-Vaxzevria). An mRNA booster dose after completion of a primary series of an mRNA vaccine or a vector vaccine improved VE against *symptomatic disease*, with four of 13 (31%) VE estimates of $\geq 70\%$, and 11 of 13 (85%) VE estimates of $\geq 50\%$ between 14 days and three months post booster. However, booster dose protection appeared to decline over time since vaccination, with one of four (25%) available estimates indicating a VE of $\geq 50\%$ at three to six months following receipt of an mRNA booster dose. VE against *infection* showed a similar pattern as that against *symptomatic disease*.

Interpretation of the results of the VE for the Delta variant

To date, 41 studies contribute evidence of the effectiveness of COVID-19 vaccines against disease and infection due to the Delta variant. VE estimates against Delta are substantially higher as compared to those against Omicron and decline more gradually over time for symptomatic disease and infection. There are only slight declines over time for VE estimates against *severe disease* caused by Delta.

For *severe disease* outcomes with the Delta variant within the first three months of vaccination with the primary series, all 10 available VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty) and four of five

(80%) VE estimates for the vector vaccines (AstraZeneca-Vaxzevria and Janssen-Ad26.COV2.S) were $\geq 70\%$. In addition, one of the two available VE estimates for the inactivated vaccines (Beijing CNBG-BBIBP-CorV and Sinovac-CoronaVac), from a study among a high risk population of close contacts of Delta index cases, was $\geq 70\%$.²⁷ Beyond three months after vaccination, all of the 23 available VE estimates for the mRNA vaccines, and five of the 10 (50%) VE estimates for the vector vaccines, were $\geq 70\%$. A booster dose improved VE against *severe disease*, with all 25 VE estimates being $\geq 70\%$ between 14 days and three months of receipt of a booster dose (22 estimates evaluated an mRNA booster, one evaluated a booster dose of AstraZeneca-Vaxzevria, and one evaluated a booster dose of Sinovac-CoronaVac). Between three and six months post mRNA booster, four of five (80%) estimates showed a VE of $\geq 70\%$.

For *symptomatic disease* and *infection*, initial VE estimates tended to be lower than against severe disease, and VE estimates decreased more significantly over time. Nonetheless, for *symptomatic disease* outcomes within the first three months of vaccination with the primary series, all 11 available VE estimates for the mRNA vaccines were $\geq 70\%$; two of four (50%) VE estimates for the vector vaccines were $\geq 70\%$. Both VE estimates for the inactivated vaccines among the high-risk group of close contacts of Delta index cases were $< 50\%$. Beyond three months after vaccination, seven of 15 (47%) VE estimates for the mRNA vaccines and none of the three VE estimates for AstraZeneca-Vaxzevria were $\geq 70\%$. An mRNA booster dose after completion of a primary series of an mRNA vaccine or AstraZeneca-Vaxzevria restored VE against *symptomatic disease* to $\geq 70\%$ in all studies (18 VE estimates) within three months of a booster dose. This persisted across six months post booster dose, with all the four VE estimates $\geq 70\%$. Limited data were available for VE of inactivated vaccines against symptomatic disease, though a similar pattern was seen with VE estimates of inactivated vaccines against *infection* over time: the single VE estimate within the first three months of completion for Sinovac-CoronaVac was $\geq 70\%$, which declined to $< 50\%$ between three to six months; however, a booster dose with various platforms following Sinovac-CoronaVac primary series restored VE to $\geq 70\%$ in all studies (six VE estimates) within the first three months of receipt of any booster dose.

WHO regional overviews:

Epidemiological week 28 March – 3 April 2022**

African Region

The African Region has continued to report a decreasing trend in weekly cases since January 2022, with just under 24 000 new weekly cases reported, representing a 19% decrease as compared to the previous week. However, nine (18%) countries in the Region reported an increase of over 20% in cases, with some of the greatest proportional increases observed in Mauritania (39 vs 4 new cases; +875%), Seychelles (442 vs 206 new cases; +115%) and Namibia (97 vs 63 new cases; +54%). The highest numbers of new cases were reported from South Africa (9802 new cases; 16.5 new cases per 100 000 population; +10%), Réunion (9756 new cases; 1089.7 new cases per 100 000; +15%), and Mauritius (794 new cases; 62.4 new cases per 100 000; -90%).

The number of new weekly deaths in the Region decreased by 21% as compared to the previous week, with over 100 new deaths reported. The highest numbers of new deaths were reported from South Africa (81 new deaths; <1 new death per 100 000 population; -6%), Ethiopia (12 new deaths; <1 new death per 100 000; +300%), and Zimbabwe (9 new deaths; <1 new death per 100 000; -18%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has also been reporting a decreasing trend in weekly cases since mid-January 2022, with over 538 000 new weekly cases reported, corresponding to a 15% decrease as compared to the previous week. However, thirteen (23%) countries in the Region reported increases in new cases of 20% or greater, with the largest increases observed in Saba (55 vs 3 new cases; +1733), Aruba (123 vs 26 new cases; +373) and Saint Barthélemy (186 vs 78 new cases; +139%). The highest numbers of new cases were reported from the United States of America (205 433 new cases; 62.1 new cases per 100 000; +2%), Brazil (172 908 new cases; 81.3 new cases per 100 000; -25%) and Canada (48 853 new cases; 129.4 new cases per 100 000; +16%).

The number of new weekly deaths decreased by 61% as compared to the previous week, when an artificial spike was observed due to changes in the definition of COVID-19 deaths in Chile and in the United States of America. The highest numbers of new deaths were reported from the United States of America (4435 new deaths; 1.3 new deaths per 100 000; -10%), Brazil (1436 new deaths; <1 new death per 100 000; -19%), and Bolivia (Plurinational State of) that shows a sharp increase in deaths due to backlog reporting (408 new deaths; 3.5 new deaths per 100 000; +8060%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline after reaching a peak in early February 2022. Just over 45 000 new weekly cases were reported last week, a 9% decrease as compared to the previous week. However, two (9%) countries in the Region have reported increases in new cases of 20% or greater: Islamic Republic of Iran (17 582 vs 9572 new cases; +84%) and Iraq (2379 vs 1956 new cases; +22%). The highest numbers of new cases were reported from the Islamic Republic of Iran (20.9 new cases per 100 000), Bahrain (5198 new cases; 305.5 new cases per 100 000; -20%) and Egypt (4375 new cases; 4.3 new cases per 100 000; -21%).

The number of new weekly deaths in the Region decreased by 16% when compared to the previous week, with just over 600 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (306 new deaths; <1 new death per 100 000; -27%), Tunisia (158 new deaths; 1.3 new deaths per 100 000; +58%), and Egypt (56 new deaths; <1 new death per 100 000; -33%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After the increase in cases observed in the European Region during the first half of March 2022, new weekly cases have decreased for the second consecutive week (-16% as compared to the previous week), with over 4.6 million new cases reported. Four (7%) countries in the Region reported increases in new cases of 20% or greater, with the largest observed in Malta (4243 vs 2434 new cases; +74%), Uzbekistan (212 vs 165 new cases; +28%) and Kyrgyzstan (89 vs 70 new cases; +27%). The highest numbers of new cases were reported from Germany (1 371 270 new cases; 1648.8 new cases per 100 000; -13%), France (959 084 new cases; 1474.6 new cases per 100 000; +13%) and Italy (486 695 new cases; 816.0 new cases per 100 000; -3%).

The number of new deaths has continued to decrease in the Region, with over 10 000 new deaths reported this week, a 15% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (2357 new deaths; 1.6 new deaths per 100 000; -18%), Germany (1592 new deaths; 1.9 new deaths per 100 000; +5%), and Italy (966 new deaths; 1.6 new deaths per 100 000; -4%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 221 000 new weekly cases, a 5% decline as compared to the previous week, continuing the decreasing trend observed since mid-January 2022. However, Bhutan reported an increase in new weekly cases of 107% (6357 vs 3076 new cases). The highest numbers of new cases were reported from Thailand (182 510 new cases; 261.5 new cases per 100 000; +4%), Indonesia (21 028 new cases; 7.7 new cases per 100 000; -42%), and India (8678 new cases; <1 new case per 100 000; -25%).

The Region reported just over 1600 new weekly deaths, representing a 73% decrease as compared to the previous week, when an artificial spike was observed due to retrospective adjustments reported from India. The highest numbers of new deaths were reported from Indonesia (618 new deaths; <1 new death per 100 000; -34%), Thailand (616 new deaths; <1 new death per 100 000; +11%), and India (341 new deaths; <1 new death per 100 000; -92%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

After the increasing trend in new cases observed in the Western Pacific Region since the end of December 2021, new weekly cases declined for a second consecutive week (-16% as compared to the previous week), with over 3.8 million new cases reported. However, seven (23%) countries in the Region reported an increase of 20% or greater, with some of the largest increases observed in Mongolia (1628 vs 622 new cases reported; +162%), Solomon Islands (1044 vs 668 new cases; +56%) and Cook Islands (828 vs 554 new cases; +49%). The highest numbers of new cases were reported from the Republic of Korea (2 058 375 new cases; 4014.8 new cases per 100 000; -16%), Viet Nam (796 725 new cases; 818.5 new cases per 100 000; -29%), and Australia (399 479 new cases; 1566.6 new cases per 100 000; +9%).

The number of new weekly deaths shows a decrease of 16% as compared to the previous week, with just under 5600 new deaths reported. The highest numbers of new deaths were reported from the Republic of Korea (2336 new deaths; 4.6 new deaths per 100 000; -5%), China (960 new deaths; <1 new death per 100 000; -34%), and Japan (549 new deaths; <1 new death per 100 000; -16%).

Updates from the [Western Pacific Region](#)

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

'Countries' may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 2. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Annex 4 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).

- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the Table

Annex 3. Methods for Figures 5 and 6

Figures include fourteen studies from the Czech Republic, Denmark, Finland, Israel, Qatar, South Africa, the United Kingdom, and the United States of America evaluating the VE against the Omicron variant, and 31 studies of the VE against the Delta variant from various countries from the European Region, Region of the Americas, and South-East Asia Region as well as Qatar and Thailand.

VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when either Delta or Omicron was the predominant circulating variant. Estimates were included if they were of laboratory-confirmed cases of the Omicron or Delta variant. In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included. For the primary series VE, estimates are only included in the plot for studies that report VE for more than one time period.

Annex 4. Summary of Primary Series Vaccine Performance against Variants of Concern (VE data as of 31 March 2022; Neutralization data as of 28 March 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺								Vaccines without WHO EUL ⁺	
	AstraZeneca-Vaxzevria/SII - Covishield	Beijing CNBG-BBIBP-CorV	Bharat-Covaxin	Janssen-Ad26.COV 2.S	Moderna-mRNA-1273	Novavax-Nuvaxovid/SII - Covavax	Pfizer BioNTech-Comirnaty	Sinovac-CoronaVac	Anhui ZL-Recombinant	Gamaleya-Sputnik V

Alpha, Beta, Gamma

Summary of VE* (see [update from 11 January 2022](#) for details of vaccine performance against Alpha, Beta, and Gamma variants of concern)

Delta²⁸

Summary of VE* Protection retained against severe disease; possible reduced protection against symptomatic disease and infection

- Severe disease	↔ ₃	-	-	↓ ₁	↔ ₄	-	↔ ₇	-	-	-

Neutralization	↓↓↓ ₇	↔to↓↓↓ ₃	↓↓ ₁	↔to↓↓↓ ₄	↓↓↓ ₁₈	-	↓↓↓ ₃₈	↓↓to↓↓↓ ₅	-	↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Annex 4 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than four months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (seven days and over after the final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (where a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., >90%).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected more than seven days and less than six months after complete vaccination and that use an ancestral strain as the reference are included in Annex 4

COVID-19 Weekly Epidemiological Update

Edition 85, published 29 March 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 27 March 2022

Between the end of January and early March 2022, there was a decreasing trend in the number of new COVID-19 cases, which was followed by two consecutive weeks of increases in cases. During the week of 21 through 27 March 2022, the number of new cases declined again with a 14% decrease as compared to the previous week (Figure 1). On the other hand, during the same period, the number of new weekly deaths increased by 43%, likely driven by changes in the definition of COVID-19 deaths in some countries in the Region of the Americas (Chile and the United States of America) and by retrospective adjustments reported from India in the South-East Asia Region.

Across the six WHO regions, over 10 million new cases and over 45 000 new deaths were reported. All regions reported decreasing trends in the number of new weekly cases and four regions reported a decreasing trend in new weekly deaths (Table 1). As of 27 March 2022, over 479 million confirmed cases and over 6 million deaths have been reported globally.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 27 March 2022**

**See [Annex 2: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the Republic of Korea (2 442 195 new cases; -13%), Germany (1 576 261 new cases; +2%), Viet Nam (1 127 716 new cases; -40%), France (845 119 new cases; +45%), and Italy (503 932 new cases; +6%).

The highest number of new weekly deaths were reported from Chile (11 858 new deaths; +1710%), the United States of America (5 367 new deaths; +83%), India (4 525 new deaths; +619%), the Russian Federation (2 859 new deaths; -22%), and the Republic of Korea (2 471 new deaths; +22%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 27 March 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	5 247 550 (49%)	-4%	198 772 221 (41%)	11 320 (25%)	-17%	1 931 515 (32%)
Western Pacific	4 615 737 (43%)	-24%	43 133 218 (9%)	6 633 (15%)	-5%	207 363 (3%)
Americas	634 618 (6%)	-14%	150 335 637 (31%)	20 737 (45%)	182%	2 694 328 (44%)
South-East Asia	232 702 (2%)	-14%	56 973 754 (12%)	6 046 (13%)	116%	777 868 (13%)
Eastern Mediterranean	50 199 (0%)	-32%	21 540 822 (4%)	811 (2%)	-22%	340 045 (6%)
Africa	24 326 (0%)	-29%	8 555 173 (2%)	164 (0%)	-30%	170 986 (3%)
Global	10 805 132 (100%)	-14%	479 311 589 (100%)	45 711 (100%)	43%	6 122 118 (100%)

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

**See [Annex 2: Data, table, and figure notes](#)

The trends reported above should be interpreted with caution as several countries are progressively changing their COVID-19 testing strategies, resulting in lower overall numbers of tests performed and consequently lower numbers of cases detected. Despite a generalized decline in the rate of SARS-CoV-2 testing observed across the six WHO regions, the number of new weekly cases increased again in early to mid-March, indicating that the virus is currently circulating at very high levels.

WHO is concerned about the recent significant reduction in SARS-CoV-2 testing by several Member States. Data are becoming progressively less representative, less timely, and less robust. This inhibits our collective ability to track where the virus is, how it is spreading and how it is evolving: information and analyses that remain critical to effectively end the acute phase of the pandemic.

Decreases in testing, unless done judiciously as part of a strategy aimed at maintaining robust surveillance where it is most impactful, may affect the capacity of countries to identify cases and enable their timely treatment or isolation, and implement other necessary control measures, with the consequent risk of increased spread of SARS-CoV-2.

This may translate in an increase in hospitalizations and deaths, and significant strains on healthcare systems, particularly in areas where public health and social measures have been lifted and where vaccination coverage

against COVID-19 is low. Furthermore, reduced testing impacts the capacity of countries to detect emerging variants early, ultimately impairing response efforts.

COVID-19 remains a Public Health Emergency of International Concern, and it is too early to reduce the quality of surveillance. The uncertainty around the characteristics of emerging variants limits our ability to confidently predict the behavior of this disease, as the evolution rate and risk of emerging variants are still high, which could undermine prevention and mitigation measures.

Until we reach the end of the acute phase of the pandemic, countries must maintain sufficient epidemiologic surveillance to inform evidence-based operational decision-making on crucial parameters, including vaccination strategies, vaccine composition, use of therapeutics, and tailored and appropriate public health and social measures.

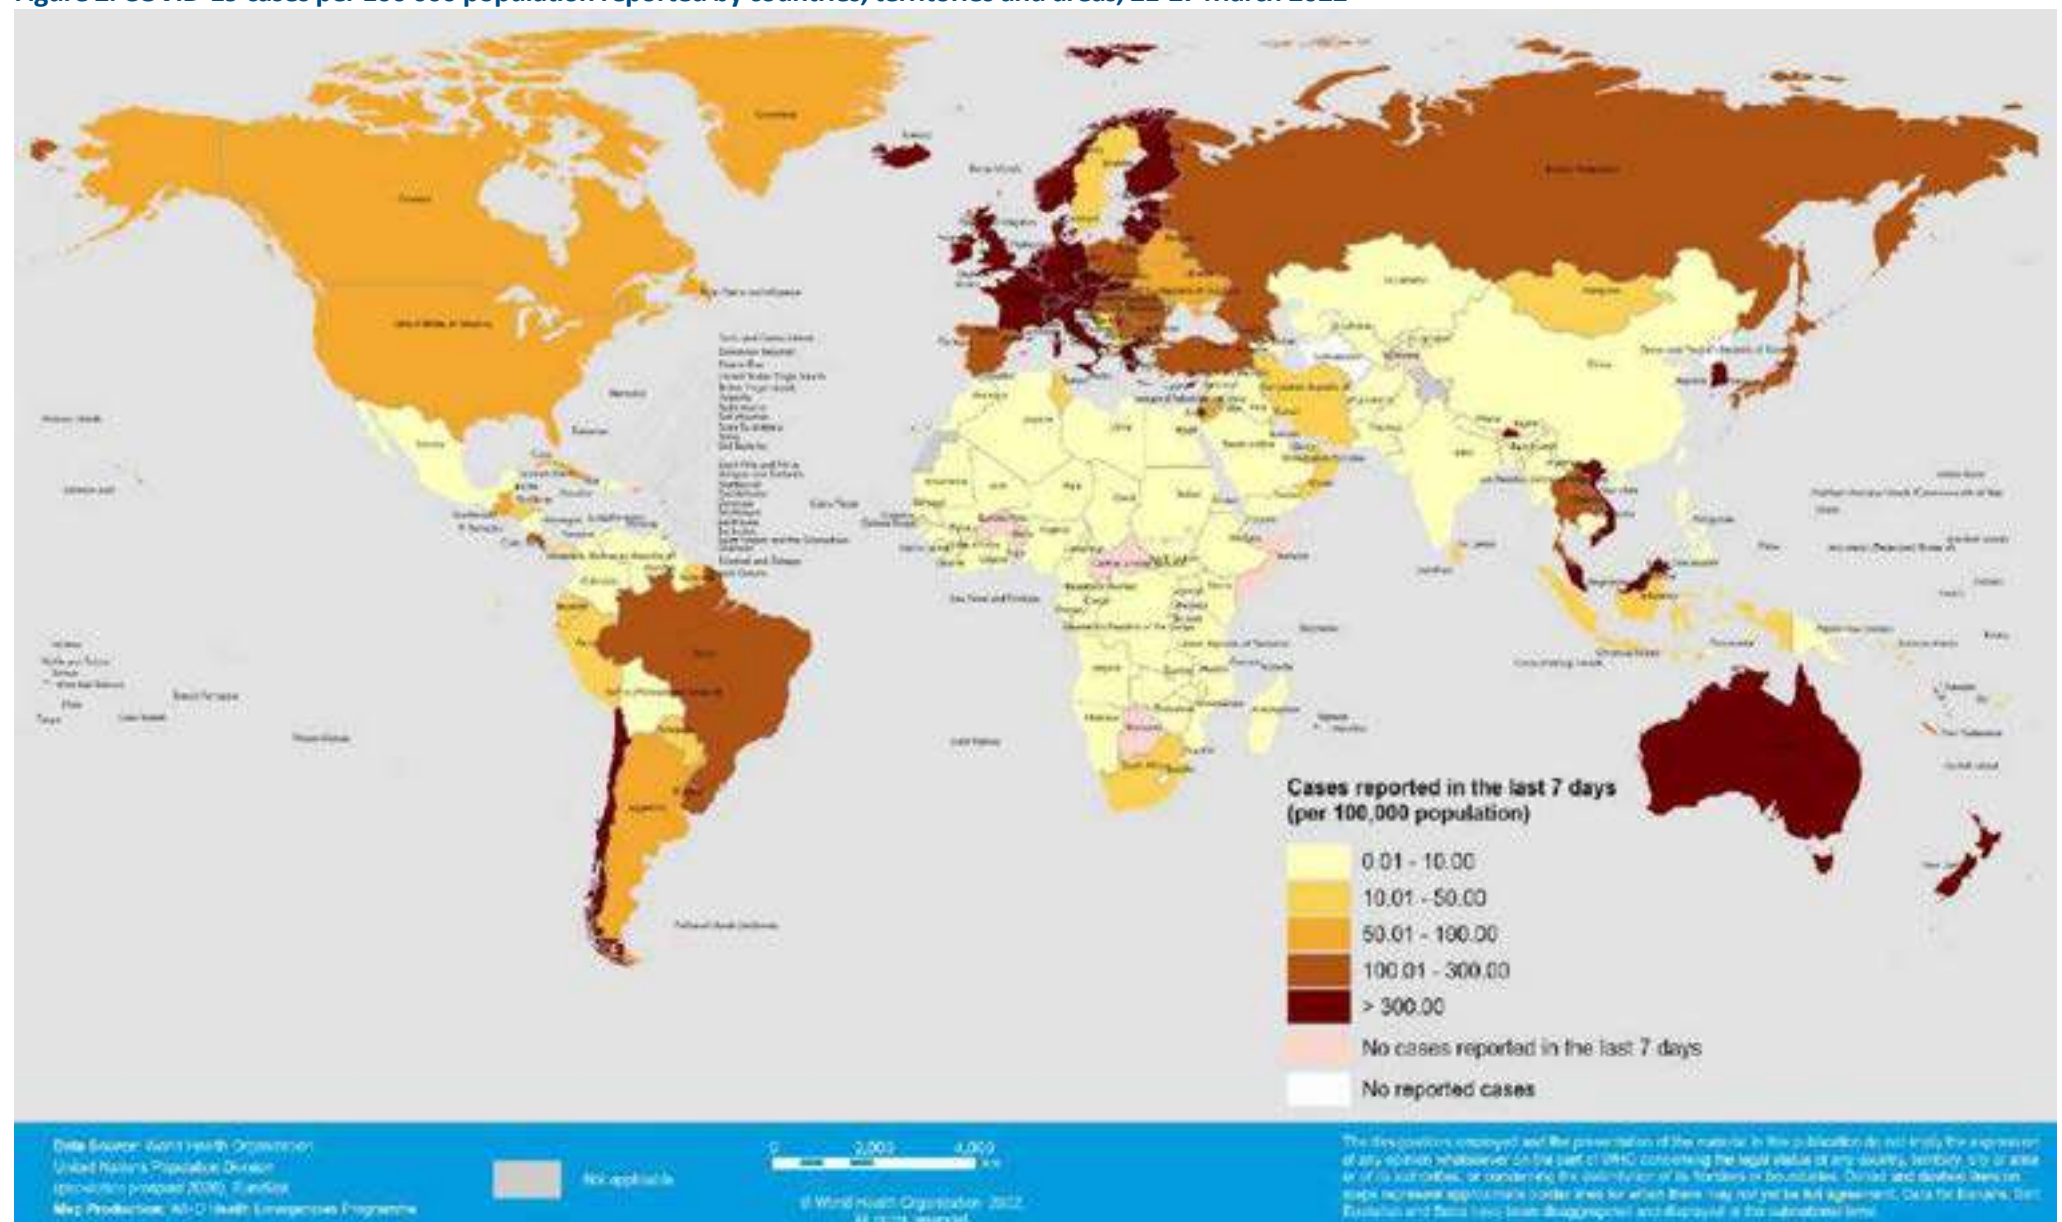

At this stage of the pandemic, WHO recommends that Member States:

- Continue representative testing financially accessible to all, providing useable and timely epidemiological evidence on the circulation of SARS-CoV-2;
- Focus on early warning and trend monitoring, which could alert to a change in the transmission dynamics of SARS-CoV-2;
- Continue with the daily tracking and reporting of cases and deaths for the duration of the acute phase of the pandemic;
- Monitor severity of COVID-19 in vulnerable groups;
- Enhance genomic surveillance to detect variants, and monitor the evolution of SARS-CoV-2.

For the latest data and other updates on COVID-19, please see:

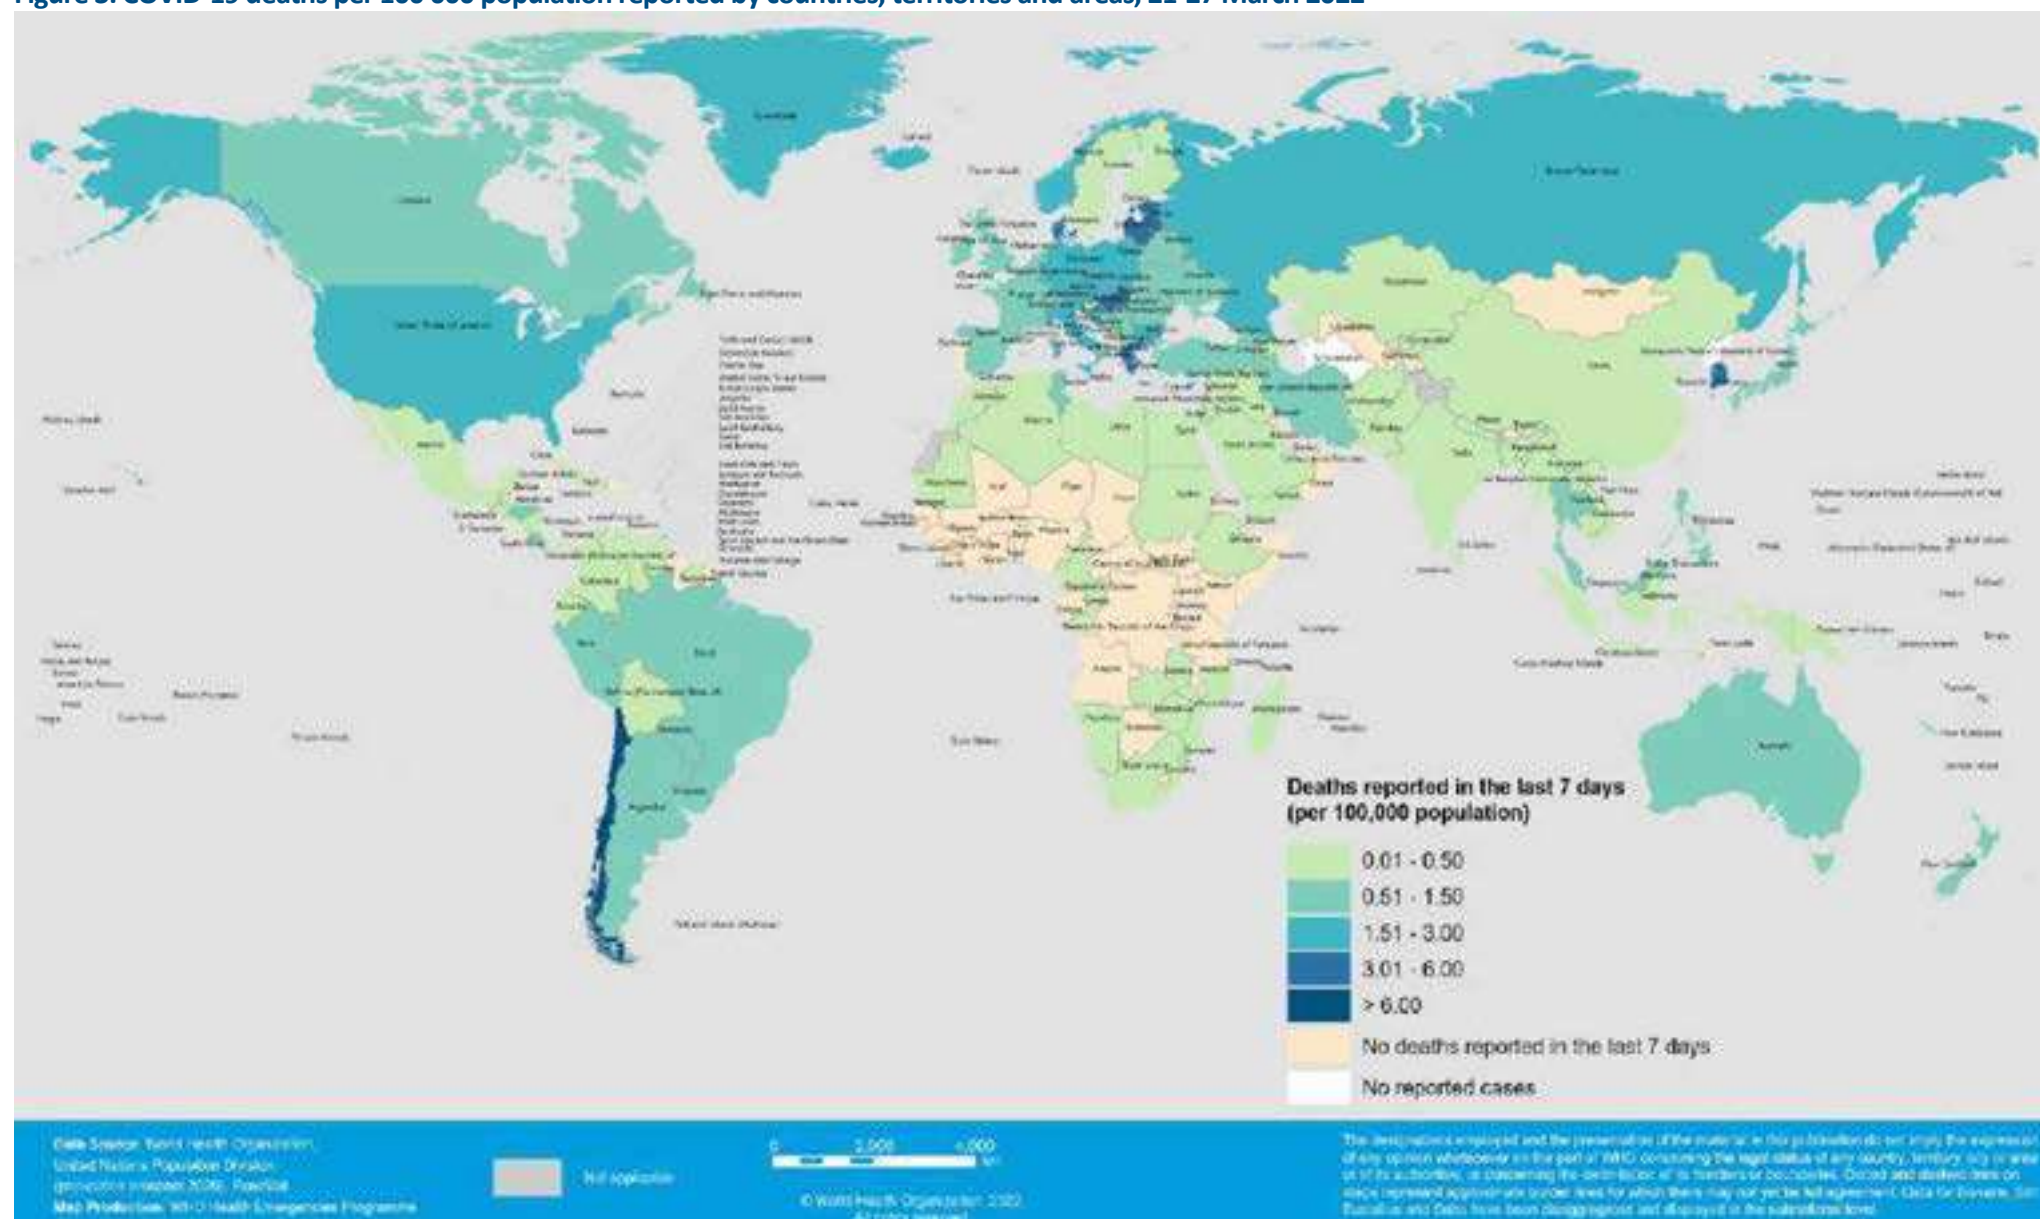

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update and previous editions of the Weekly Epidemiological Update](#)

Figure 2. COVID-19 cases per 100 000 population reported by countries, territories and areas, 21-27 March 2022*

**See [Annex 2: Data, table, and figure notes](#)

Figure 3. COVID-19 deaths per 100 000 population reported by countries, territories and areas, 21-27 March 2022**

**See [Annex 2: Data, table, and figure notes](#)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the global dominance of the Omicron variant. Among the 382 789 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 381 824 (99.7%) were Omicron, 175 (<0.1%) were Delta, and 649 sequences were not assigned to a Pango lineage (0.2%).

To note, the global distribution of VOCs should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting. In addition, some countries may have changed their testing and sequencing policies during the presented period.

Recombinant variants

The same process of risk assessment is applied to recombinant variants as for any other emerging variant. Since the [epidemiological update published on 22 March 2022](#), no new evidence indicates that the recombinant variant assigned XD Pango lineage (Delta-Omicron) is associated with higher transmissibility or more severe outcomes. The XE recombinant (BA.1-BA.2), was first detected in the United Kingdom on 19 January and >600 sequences have been reported and confirmed since. Early-day estimates indicate a community growth rate advantage of ~10% as compared to BA.2, however this finding requires further confirmation. XE belongs to the Omicron variant until significant differences in transmission and disease characteristics, including severity, may be reported. WHO continues to closely monitor and assess the public health risk associated with recombinant variants, alongside other SARS-CoV-2 variants, and will provide updates as further evidence becomes available.

ⁱIncludes sequences submitted to [GISAID](#) with sample collected dates from 23 February to 24 March 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 44 countries submitted a total of 100 sequences and above on GISAID.

WHO regional overviews:

Epidemiological week 21-27 March 2022**

African Region

The decreasing trend observed in the African Region since January 2022 continues, with over 24 000 new weekly cases reported, representing a 29% decrease as compared to the previous week. However, fourteen (29%) countries in the Region reported an increase of over 20% in cases, with some of the greatest proportional increases observed in Equatorial Guinea (101 vs 4 new cases; +2425%), Lesotho (105 vs 59 new cases; +78%), and Rwanda (71 vs 48 new cases; +48%). The highest numbers of new cases were reported from South Africa (8934 new cases; 15.1 new cases per 100 000 population; -9%), Réunion (8494 new cases; 948.7 new cases per 100 000; similar to the previous week's figures), and Mauritius (2410 new cases; 189.5 new cases per 100 000; -77%).

The number of new weekly deaths in the Region decreased by 30% as compared to the previous week, with over 150 new deaths reported. The highest numbers of new deaths were reported from South Africa (86 new deaths; <1 new death per 100 000 population; -49%), Mauritius (34 new deaths; 2.7 new deaths per 100 000 population; similar to the previous week's figures, and Réunion (13 new deaths; 1.5 new deaths per 100 000; +44%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has been reporting a decreasing trend since mid-January 2022, with over 634 000 new weekly cases reported, corresponding to a 14% decrease as compared to the previous week. However, eleven (20%) countries in the Region reported increases in new cases of 20% or greater, with the greatest increases observed in the islands of Sint Eustatius (142 vs 13 new cases; +992%), Anguilla (39 vs 20 new cases; +95%) and Saint Pierre and Miquelon (577 vs 298 new cases; +94%). The highest numbers of new cases were reported from Brazil (229 145 new cases; 107.8 new cases per 100 000; -15%), the United States of America (207 093 new cases; 62.6 new cases per 100 000; -6%), and Chile (61 337 new cases; 320.9 new cases per 100 000; -36%).

The Region reported over 20 000 new weekly deaths, a 182% increase as compared to the previous week, which was partly due to changes in the definition of COVID-19 deaths in Chile and in one state in the United States of America. The highest numbers of new deaths were reported from Chile (11 858 new deaths; 62.0 new deaths per 100 000; +1710%), the United States of America (5367 new deaths; 1.6 new deaths per 100 000; +83%), and Brazil (1768 new deaths; <1 new death per 100 000; -21%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline following a peak reached in early February 2022. Just over 50 000 new weekly cases were reported, a 32% decrease as compared to the previous week. However, two (9%) countries in the Region have reported increases in new cases of 20% or greater: Tunisia (3969 vs 534 new cases; +643%) and occupied Palestinian territory (1088 vs 718 new cases; +52%). The highest numbers of new cases were reported from the Islamic Republic of Iran (9572 new cases; 11.4 new cases per 100 000; -51%), Jordan (9135 new cases; 89.5 new cases per 100 000; -64%), and Bahrain (6527 new cases; 383.6 new cases per 100 000; -14%).

The number of new weekly deaths in the Region decreased by 22% when compared to the previous week, with just over 800 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (421 new deaths; <1 new death per 100 000; -41%), Tunisia (100 new deaths; <1 new death per 100 000; +426%), and Egypt (84 new deaths; <1 new death per 100 000; -20%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 5.2 million new weekly cases, representing a 4% decrease as compared to the previous week. Six (10%) countries in the Region reported increases in new cases of 20% or greater, with the largest observed in Israel (88 869 vs 47 796 new cases; +86%), Hungary (15 269 vs 9727 new cases; +57%) and Malta (2434 vs 1628 new cases; +50%). The highest numbers of new cases were reported from Germany (1 576 261 new cases; 1895.3 new cases per 100 000; +2%), France (845 119 new cases; 1299.4 new cases per 100 000; +45%), and Italy (503 932 new cases; 844.9 new cases per 100 000; +6%).

The number of new deaths has continued to decrease in the Region, with over 11 000 new deaths reported this week, a 17% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (2859 new deaths; 2.0 new deaths per 100 000; -22%), Germany (1521 new deaths; 1.8 new deaths per 100 000; +13%), and Italy (1008 new deaths; 1.7 new deaths per 100 000; +11%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 232 000 new weekly cases, a 14% decline as compared to the previous week, continuing the decreasing trend observed since mid-January 2022. However, Sri Lanka reported an increase in new weekly cases of 25% (2693 vs 2156 new cases). The highest numbers of new cases were reported from Thailand (175 116 new cases; 250.9 new cases per 100 000; +4% increase), Indonesia (36 470 new cases; 13.3 new cases per 100 000; -49%), and India (11 612 new cases; <1 new case per 100 000; -31%).

The Region reported just over 6000 new weekly deaths, representing a 116% increase as compared to the previous week. The highest numbers of new deaths were reported from India (4525 new deaths; <1 new death per 100 000; +619%) due to retrospective adjustments in some states, followed by Indonesia (932 new deaths; <1 new death per 100 000; -41%), and Thailand (553 new deaths; <1 new death per 100 000; +3%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

With over 4.6 million new weekly cases, the Region reported a 24% decrease as compared to the previous week, reversing the increasing trend observed since the end of December 2021. Seven (23%) countries in the Region reported an increase of 20% or greater, with some of the largest increases observed in Vanuatu (1234 vs 352 new cases; +251%), Guam (487 vs 142 new cases; +243%) and Lao People's Democratic Republic (16 037 vs 6449; +149%). The highest numbers of new cases were reported from the Republic of Korea (2 442 195 new cases; 4763.5 new cases per 100 000; -13%), Viet Nam (1 127 716 new cases; 1158.5 new cases per 100 000; -40%), and Australia (368 028 new cases; 1443.3 new cases per 100 000; -28%).

The number of new weekly deaths shows a decrease of 5% as compared to the previous week, with just over 6600 new deaths reported. The highest numbers of new deaths were reported from the Republic of Korea (2471 new deaths; 4.8 new deaths per 100 000; +22%), China (1453 new deaths; <1 new death per 100 000; -24%), and the Philippines (861 new deaths; <1 new death per 100 000; +48%).

*Newly reported in this update. “●” indicates that information for this variant was received by WHO from official sources. “○” indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information becomes available. **Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 84, published 22 March 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 20 March 2022

After a consistent decrease since the end of January 2022, the number of new weekly cases rose for a second consecutive week, with a 7% increase reported during the week of 14 through 20 March 2022, as compared to the previous week. The number of new deaths has continued a decreasing trend (-23% as compared to the previous week) (Figure 1). Across the six WHO regions, over 12 million cases and just under 33 000 deaths were reported (Table 1). As of 20 March 2022, over 468 million confirmed cases and just over 6 million deaths have been reported globally.

At the regional level, the number of new weekly cases increased in the Western Pacific Region (+21%), remained stable in the European Region, and decreased in the Eastern Mediterranean (-41%), Africa (-33%), South-East Asia (-23%) and Americas (-17%) regions. On the other hand, the number of new weekly deaths increased in the Western Pacific Region (+5%), while decreasing in the other regions: Americas (-42%), Eastern Mediterranean (-38%), Africa (-19%), Europe (-18%) and South-East Asia (-18%).

These trends should be interpreted with caution as several countries are progressively changing their testing strategies, resulting in lower overall numbers of tests performed and consequently numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 20 March 2022**

**See [Annex 2: Data, table, and figure notes](#)

At the country level, the highest number of new weekly cases were reported from the Republic of Korea (2 817 214 new cases; +34%), Viet Nam (1 888 694 new cases; +13%), Germany (1 538 666 new cases; +14%), France (582 344 new cases; +39%), and Australia (513 388 new cases; +161%).

The highest number of new weekly deaths were reported from the Russian Federation (3 681 new deaths; -19%), the United States of America (3 612 new deaths; -58%), Brazil (2 242 new deaths; -32%), the Republic of Korea (2 033 new deaths; +41%), and China (1 921 new deaths; -2%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 20 March 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Western Pacific	6 055 914 (49%)	21%	38 516 204 (8%)	6 995 (21%)	5%	200 735 (3%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the global dominance of the Omicron variant. Among the 412 982 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 412 119 (99.8%) were Omicron and 259 (0.1%) were Delta.

Since the first reporting of the Omicron variant in November 2021, more than 2.4 million sequences have been deposited in GISAID. By the first week of January 2022, Omicron accounted for 90% of submitted sequences; by week five, Omicron had largely replaced all other variants and now accounts for over 99.8% of submitted sequences globally.

Omicron has a number of descendant lineages, including BA.1, BA.1.1, BA.2 and BA.3. In the last 30 daysⁱⁱ, BA.2 has become the predominant variant, with 251 645 sequences (85.96%) reported. During the same period, 125 485 BA.1.1 sequences (8.98%), 54 724 BA.1 sequences (4.26%) and 70 BA.3 sequences (<0.1%) have been also uploaded to GISAID.

Among the major Omicron descendent lineages, weekly trends (figure 4, panel A) show that the relative proportion of BA.2 has increased steadily since the end of 2021, with BA.2 becoming the dominant lineage by week seven of 2022. This trend is most pronounced in the South-East Asia Region, followed by the Eastern Mediterranean, African, Western Pacific and European Regions. BA.2 is currently dominant in the Region of the Americas.

However, the absolute numbers of submitted BA.1 and BA.1.1 sequences, as well as an apparent plateau in the absolute number of BA.2 sequences indicate a recent declining trend in the descendent lineages of Omicron since the beginning of 2022 (figure 4, panel B). This trend should be interpreted with some caution, as data for the most recent weeks may be incomplete due to the delay between specimen collection and submission of sequences to GISAID.

To note, the global distribution of VOCs should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting. In addition, some countries may have changed their testing and sequencing policies during the presented period.

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 16 February to 17 March 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 47 countries submitted a total of 100 sequences and above on GISAID.

ⁱⁱ Please note that uploaded GISAID data for the maps and the global epidemiological reporting are slightly different in absolute numbers as compared to Omicron descendent lineage sequence data. The latter is taken from the manual [GISAID](#) data availability.

Figure 4. Global distribution and relative proportion of Omicron lineages for sequences submitted to GISAID presented by week of specimen collection

Panel A. Relative proportions of Omicron lineages over the last 4 weeks by specimens collection week

Lineage	Countries	Sequences ^a	SGTF ^b	Overall (%)		Last 4 weeks by collection date (%)			
				Total		2022-08	2022-09	2022-10	2022-11
BA.1	164	1 077 755	96.26	44.40		15.21	8.24	3.98	4.26
BA.1.1	151	913 277	95.72	37.62		34.51	22.29	11.61	8.98
BA.2	106	431 242	0.18	17.77		49.93	69.12	83.95	85.96
BA.3	21	648	96.91	0.03		0.01	0.02	0.01	0.00
Unassigned	62	4 536	34.99	0.19		0.35	0.34	0.44	0.80

SARS-CoV-2 recombinant variants

Recombination of variants of the same virus is a natural phenomenon and can be regarded as an expected mutational event. WHO has been notified of several recombinant variants, either recombination between Delta and BA.1 variants, or BA.1 and BA.2 variants. The same monitoring and assessment process is applied to these recombinants as for any other emerging variant, after verification and exclusion of potential contamination or co-infection. Two Delta and Omicron recombinants and one BA.1 x BA.2 recombinant have now been given Pango lineage designations XD, XE and XF. None of the preliminary available evidence indicates that these recombinant variants are associated with higher transmissibility or more severe outcomes. WHO continues to monitor recombinant variants, alongside other SARS-CoV-2 variants, and will provide updates as further evidence becomes available.

Characteristics of Omicron

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last update on 8 March 2022](#), there have been several new publications on the phenotypic characteristics of VOCs, including literature on Omicron (Table 2). Some of these studies have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Table 2: Summary of current evidence on Omicron

Domain	Indicator	Main results
Epidemiology	Impact on disease prevalence/incidence	<p>After a consistent decrease since the end of January 2022, for the second week in a row, the number of new weekly cases increased by 7% during the week of 14 through 20 March 2022, as compared to the previous week. The number of new weekly cases increased in the Western Pacific Region (+21%), remained stable in the European Region, while decreased in the Eastern Mediterranean Region (-41%), Africa Region (-33%), South-East Asia Region (-23%) and the America Region (-17%). It is important to note that changes in testing policies may influence the number of reported cases.</p> <p>The Omicron variant is the dominant circulating variant globally, representing 99.8% of samples collected between 16 February and 17 March 2022 (GISAID), while the Delta variant represents 0.1%. Among the Omicron Pango lineages, BA.2 is now the most prevalent (86%), followed by BA.1.1 (9%), BA.1 (4%) and BA.3 (<0.1%).</p>
	Impact on transmission	<p>An updated analysis of GISAID data¹ shows Omicron still having a growth rate advantage over Delta in 67 countries with sufficient sequence data available up to 21 March 2022, translating to a pooled mean transmission advantage (i.e. relative difference in effective reproduction numbers) of 5% (95% CI: 74%-103%) across epidemiological contexts under the assumption of an unchanged generation time (i.e. duration between the moment a person gets infected to the moment they infect another person). However, evidence for a reduced generation time of Omicron suggests the transmission advantage may be lower; for a 20% shorter generation time, the estimated pooled mean transmission advantage of Omicron over Delta is 74% (95% CI: 66%-90%). The same analysis demonstrates a growth rate advantage of the Omicron Pango lineage BA.2 over the Pango lineage BA.1, with a pooled mean transmission advantage of 72% (95% CI: 55%-82%) under the assumption of an unchanged generation time. These estimates are stabilising as the number of Omicron sequences is increasing and data become available from more countries.</p> <p>An updated analysis published on 11 March 2022 by the United Kingdom², which used data on samples collected between 01 December 2021 and 01 March 2022, confirms that BA.2 has a higher growth rate compared to BA.1 (median: 78.8 % per week) and higher secondary attack rates for household (13.6%; 95%CI: 13.2%-14.0% vs. 10.7%; 95%CI: 10.6%-10.8%) and non-household (5.3%; 95%CI:4.7%-5.8% vs. 4.2%; 95%CI: 4.0%-4.3%) contacts.</p>
	Impact on disease severity	<p>Omicron has consistently been found to have lower severity when compared to Delta across different settings³⁻⁷. An updated analysis comparing patients infected with BA.1 and BA.2 shows similar findings to previously published data, with no difference in the risk of hospitalisation (HR=0.91; 95% CI: 0.85-0.98) in the United Kingdom².</p> <p>There is still a sustained decrease in the number of reported hospitalisations since the end of January 2022 in the United States of America⁸ and South Africa⁹ while the United Kingdom reported an increase in hospitalisations in week 10 (7-10 March) compared to week 9 (28 February – 6 March) of 2022 (13.38 per 100,000 vs 11.67 per 100,000)¹⁰.</p>
Immune response	Impact on reinfection	<p>Higher rates of reinfection have been reported for the Omicron variant among individuals previously infected with other SARS-CoV-2 variants. Reinfection with BA.2 following BA.1 was associated with mild disease in Denmark¹¹ while a study conducted in Qatar reported that previous infection with one of the Omicron Pango lineages may confer protection against infection with other Omicron Pango lineages; 94.9% (95% CI: 88.4-97.8%) protection against BA.2 following infection with BA.1, and 85.6% (95% CI: 77.4-90.9%) protection against BA.1 following infection with BA.2¹².</p>
	Impact on vaccination	<p>Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). For further information, see the section Interpretation of the results of the VE for the Omicron variant.</p>

Domain	Indicator	Main results
	Impact on antibody responses	There are no new data on antibody responses to Omicron since the last update . An analysis of neutralization data from 23 laboratories found a 20-fold reduction in neutralization associated with the Omicron variant ¹³ . These findings are consistent with results of recent studies that reported lower neutralising antibody titers to BA.1 and BA.2 compared to wild-type SARS-CoV-2 and similar responses for BA.1 and BA.2 ^{14,15} . Another recent study found similar non-neutralising antibody responses to BA.1 and BA.2 in vaccinated individuals ¹⁶ . Overall, these results indicate similar humoral responses to BA.1 and BA.2.
Diagnostic tools	Impact on PCR assays	There is no new evidence on the impact of Omicron on PCR assays, which include multiple gene targets. The BA.2 lineage is the only descendant variant of Omicron that lacks the 69-70 deletion responsible for S-gene target failure. Assessment of PCR tests for SARS-CoV-2 that include multiple gene targets predicted limited impact of the Omicron variant on the accuracy of these assays ^{17,18} .
	Impact on Rapid Diagnostic tests	There is no new evidence on the impact of Omicron on antigen-based rapid diagnostic tests (Ag-RDTs). Available data show contradictory results on the diagnostic performance of Ag-RDTs to detect Omicron compared to other variants: while some studies have shown reduced sensitivity of Ag-RDTs ^{19–22} , others have reported comparable sensitivity of Ag-RDT tests to detect Omicron compared to Delta or other VOCs ^{23–26} .
Impact on treatment	Impact on antivirals	There has been no new evidence since the publication of preliminary data showing no difference in the effectiveness of antiviral agents against the Omicron variant ^{27–29} .
	Impact on biologicals	Initially, studies on the effectiveness of monoclonal antibodies for treating patients with Omicron reported conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduction in effectiveness of other monoclonal antibodies ^{30–34} . However, additional preclinical evidence shows reduced neutralizing activity of sotrovimab against the BA.2 Pango lineage and lack of efficacy of casirivimab-imdevimab against the BA.1 Omicron Pango lineage ³⁵ .
	Other treatment options	There is no evidence to suggest that Interleukin-6 receptor blockers and corticosteroids are not effective in the management of patients with severe and critical disease.

Figure 5. Vaccine effectiveness (VE) of primary series and booster vaccination against the Delta variant of concern

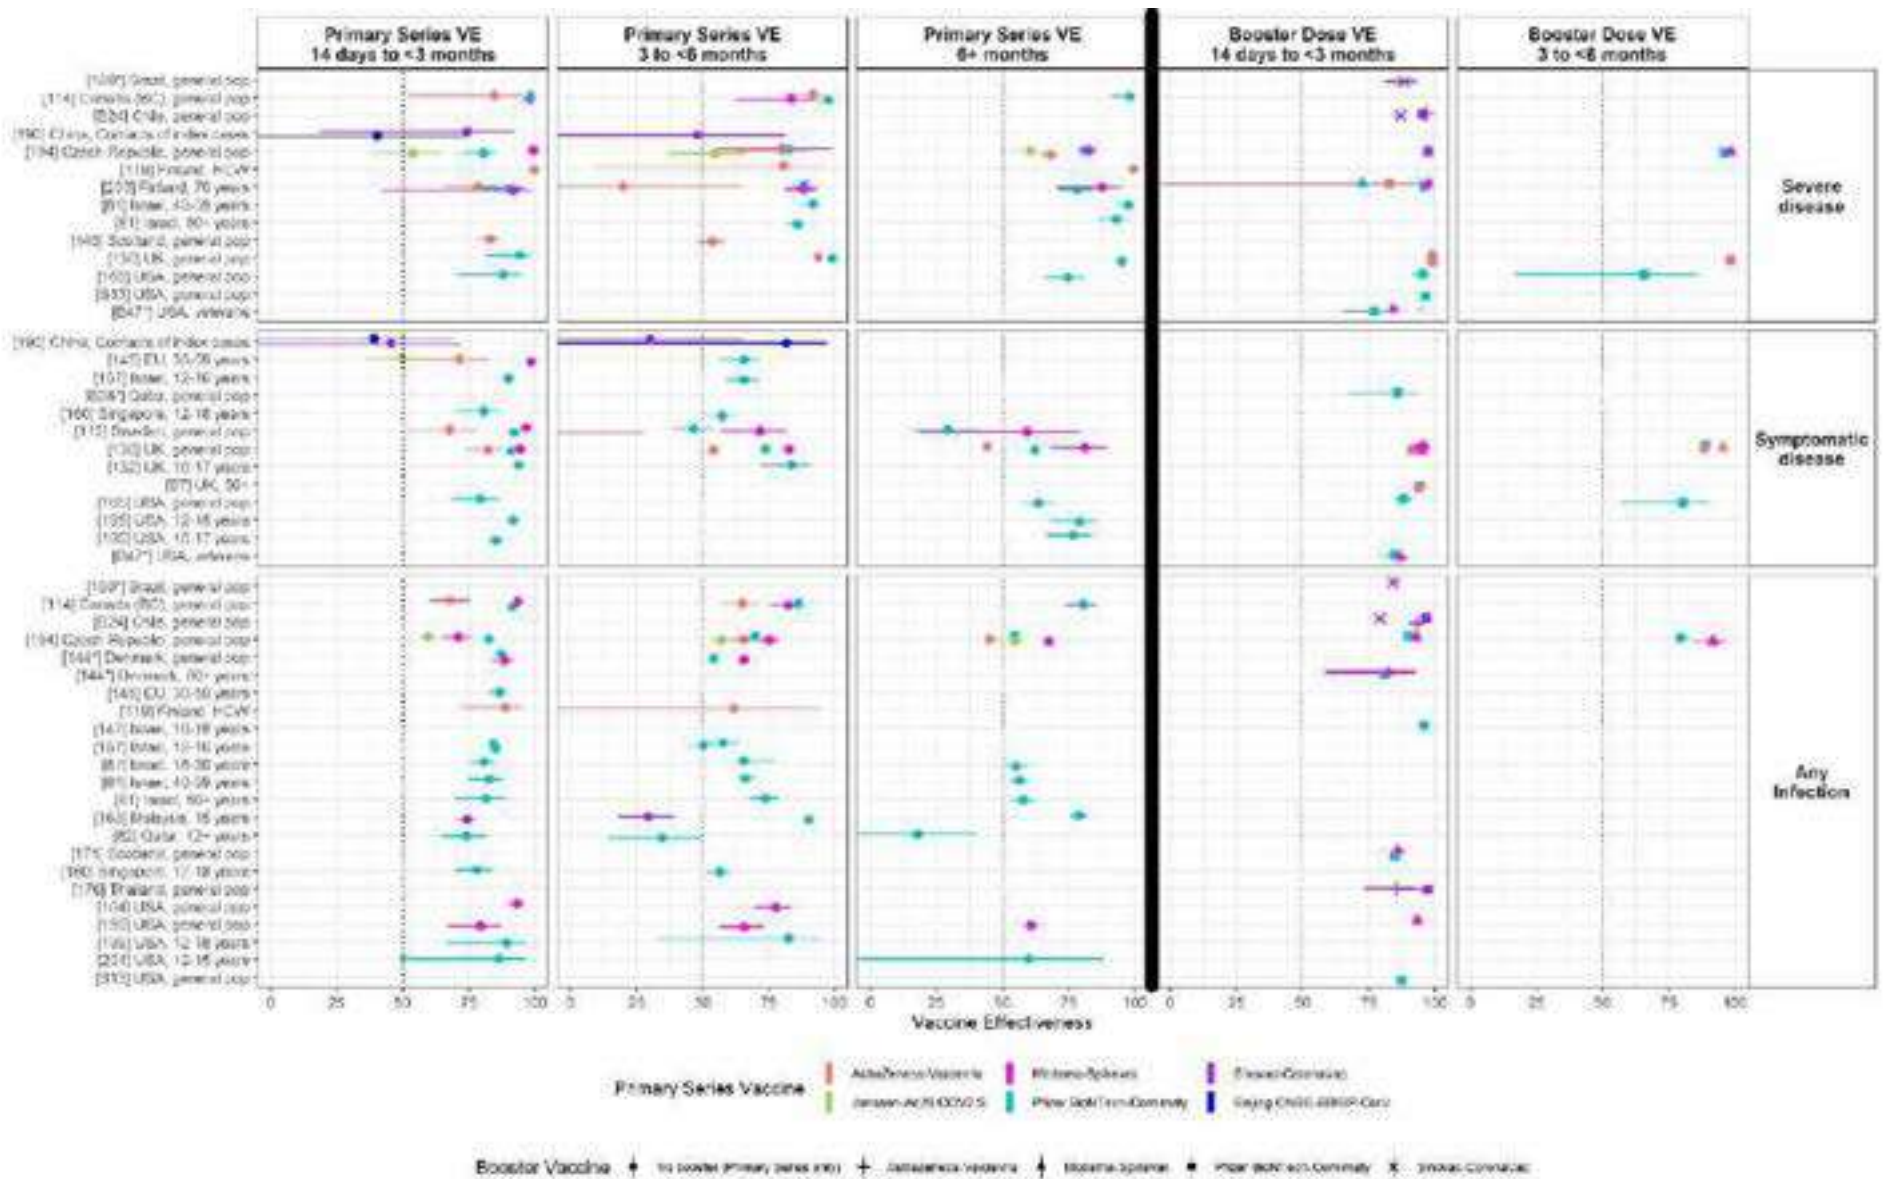

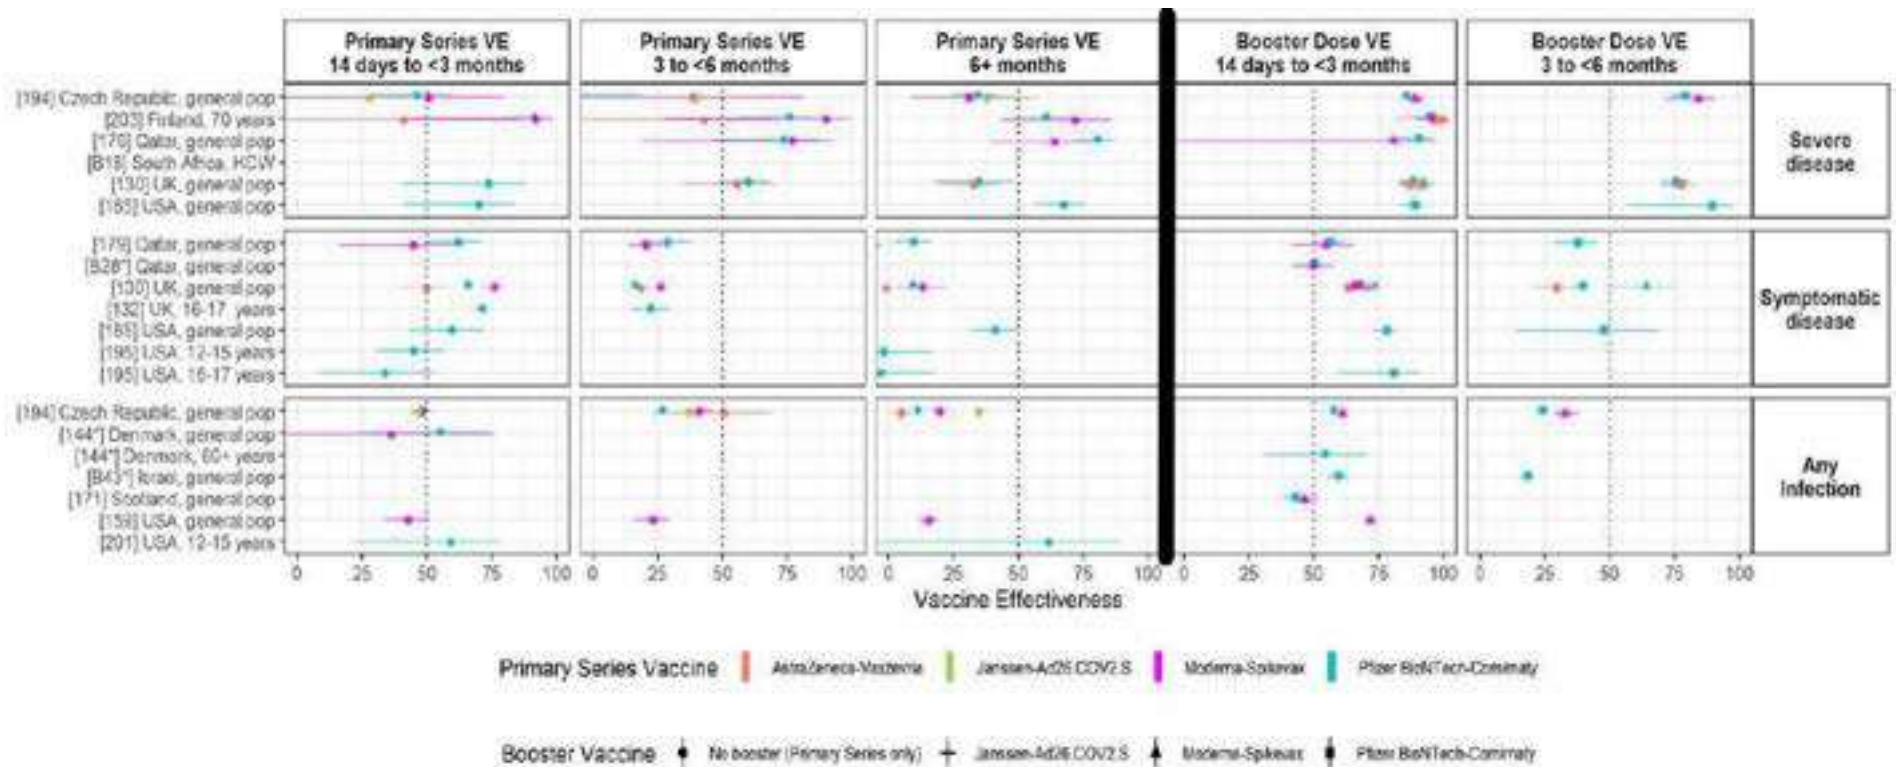

Figure 6. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

*Indicates booster dose vaccine effectiveness evaluated using persons completing primary series as reference group, rather than unvaccinated persons. Abbreviations: pop=population; HCW=healthcare workers; EU=European Union. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the [summary table](#) of VE effectiveness studies on [view-hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes severe disease, hospitalization, and pneumonia; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, three negative point estimates for the primary series are not shown in the Omicron plot: Moderna-Spikevax VE against symptomatic disease at 6+ months (reference 179) as well as Moderna-Spikevax and Pfizer BioNTech-Comirnaty VE against infection at 3-6 months (reference 144); one negative point estimate for primary series is not shown in the Delta plot: AstraZeneca-Vaxzevria VE against Delta symptomatic disease (reference 112) with 95% CIs crossing 0 is not fully visible in the plot.

Figures 5 and 6 summarize the impact of Delta and Omicron variants, respectively, on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Since the last [update](#), five new studies, all of which assessed VE against Delta and three which also assessed VE against Omicron, have been added to the figures.^{36–40} Of the Omicron studies, one study provided new VE data on AstraZeneca-Vaxzevria³⁷, two (not yet peer-reviewed) on Moderna-Spikevax^{37,38}, and four (two not yet peer-reviewed) on Pfizer BioNTech-Comirnaty.^{37–40} Additional information on vaccine performance against VOCs can also be found in Annex 4.

Interpretation of the results of the VE for the Delta variantⁱⁱⁱ

To date, 31 studies contribute evidence of the effectiveness of COVID-19 vaccines against disease and infection due to the Delta variant. VE against Delta is substantially higher than that of Omicron and declines more gradually over time for *symptomatic disease* and *infection*, with only slight declines over time against *severe disease*.

For *severe disease* outcomes with the Delta variant within the first three months of vaccination with the primary series, all eight (100%) VE estimates for the mRNA vaccines (Moderna-Spikevax and Pfizer BioNTech-Comirnaty) and four of five (80%) VE estimates for the adenovector vaccines (AstraZeneca-Vaxzevria and Janssen-Ad26.COV2.S) were $\geq 70\%$. Beyond three months after vaccination, all 18 (100%) VE estimates for the mRNA vaccines and five of 10 (50%) VE estimates for the adenovector vaccines were $\geq 70\%$.

For *symptomatic disease* and *infection*, initial VE estimates tended to be lower than against *severe disease*, and VE decreased more significantly over time. Still, for *symptomatic disease* outcomes within the first three months of vaccination with the primary series, all 11 (100%) VE estimates for the mRNA vaccines were $\geq 70\%$; two of four (50%) VE estimates for the adenovector vaccines were $\geq 70\%$. Beyond three months after vaccination, seven of 15 (47%) VE estimates for the mRNA vaccines and none of three (0%) VE estimates for the adenovector vaccines were $\geq 70\%$. mRNA booster vaccination after completion of a primary series of an mRNA vaccine or of AstraZeneca-Vaxzevria restored VE against *symptomatic disease* to $\geq 70\%$ in all studies (12/12 estimates) within three months of a booster dose which persisted through six months post booster (all four VE estimates $\geq 70\%$). Limited data were available for VE of inactivated vaccines (Beijing CNBG-BBIBP-CorV and Sinovac-CoronaVac) against *symptomatic disease*, though a similar pattern was seen with VE of inactivated vaccines against *infection* over time: the only VE estimate within the first three months of completion of Sinovac-CoronaVac was $\geq 70\%$, which declined to $<50\%$ at three to six months; however, booster vaccination with various platforms following Sinovac-CoronaVac primary series restored VE to $\geq 70\%$ in all studies (6/6 VE estimates) within the first three months of receipt of any booster dose.

Interpretation of the results of the VE for the Omicron variantⁱⁱⁱ

To date, ten studies of VE against the Omicron variant show reduced protection of the primary series COVID-19 vaccines for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for other variants of concern. Importantly though, VE estimates against the Omicron variant remain highest for *severe disease*, while they are lower for *symptomatic disease* and *infection*. Booster vaccination substantially improves VE for all outcomes for all products. However, due to short follow-up time after boosters, more data are needed to

ⁱⁱⁱ Summarize the totality of the evidence for Omicron and Delta by disease outcome (infection, symptomatic disease, severe disease) for each of the vaccine platforms by calculating the proportion of all VE estimates that are at or above 70% within each vaccine platform for each disease outcome. Please note that a single study may contribute multiple VE estimates.

characterize the duration of VE following a booster dose. No data is yet available on the duration of protection of inactivated vaccines against Omicron.

For *severe disease*, within the first three months of primary series vaccination, four of six (67%) VE estimates for the mRNA vaccines were $\geq 70\%$, with only two studies available for vector vaccines both which reported a VE of $< 50\%$. Beyond three months after vaccination, six of 15 (40%) VE estimates for the mRNA vaccines and none of five (0%) VE estimates for the adenovector vaccines were $\geq 70\%$. Booster vaccination improved VE against *severe disease* in all studies, with all 16 estimates showing VE $\geq 70\%$ (15 estimates evaluated an mRNA booster and one estimate evaluated a booster dose of Janssen-Ad26.COV2.S) between 14 days and three months of receipt of a booster dose. At three to six months post mRNA booster, all five (100%) estimates showed VE $\geq 70\%$.

Initial VE estimates against *symptomatic disease* and *infection* tended to be lower than against *severe disease*, and VE decreased more substantially over time. For *symptomatic disease*, outcomes within the first three months of vaccination with the primary series, two of eight (25%) VE estimates for the mRNA vaccines were $\geq 70\%$ and none of the VE estimates for the adenovector vaccines (AstraZeneca-Vaxzevria and Janssen-Ad26.COV2.S). Beyond three months after vaccination, none of 12 (0%) VE estimates for the mRNA vaccines and none of two (0%) VE estimates for AstraZeneca-Vaxzevria were $\geq 50\%$. mRNA booster vaccination after completion of a primary series of an mRNA vaccine or of AstraZeneca-Vaxzevria improved VE against *symptomatic disease* with four of 10 (40%) VE estimates $\geq 70\%$ and all 12 (100%) $\geq 50\%$ 14 days to three months post booster. However, booster dose protection declined with time since vaccination with one of five (20%) of available estimates indicating a VE of $\geq 50\%$ at three to six months following receipt of an mRNA booster dose. VE against *infection* showed a similar pattern.

One new pre-print study from Chile (not included in the plots due to not meeting the criterion of presenting VE estimates for more than one time point after vaccination) assessed VE of Sinovac-CoronaVac against *infection* and hospitalization among children aged three to five years during an Omicron dominant period.⁴¹ VE against hospitalization and infection 14 or more days after receipt of the second dose of Sinovac-CoronaVac was 65.2% (95% CI: 50.4-75.6%) and 37.9% (95% CI: 36.1-39.6%), respectively, with a maximum follow-up time of approximately 14 weeks following receipt of the second dose.

WHO regional overviews Epidemiological week 14-20 March 2022**

African Region

The Africa Region reported over 25 000 new cases, a 33% decrease as compared to the previous week. The number of cases has continued to decrease since late December 2021. Nine (18%) countries in the Region reported an increase in cases by over 20% this week, although these countries reported fewer than 100 new cases. The highest numbers of new cases were reported from South Africa (9797 new cases; 16.5 new cases per 100 000 population; similar to the previous week's figures), Réunion (8514 new cases; 951.0 new cases per 100 000; +6%), and Zimbabwe (2095 new cases; 14.1 new cases per 100 000; -37%).

The number of new weekly deaths in the Region decreased by 19% as compared to the previous week, with over 200 new deaths reported. The highest numbers of new deaths were reported from South Africa (167 new deaths; <1 new death per 100 000 population; similar to the previous week's figures), Zimbabwe (12 new deaths; <1 new death per 100 000; -29%), Algeria (9 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Réunion (9 new deaths; 1.0 new deaths per 100 000; -36%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 738 000 new cases and over 8800 new deaths, decreases of 17% and 42% respectively as compared to the previous week. However, 13 (23%) countries in the Region reported increases in new cases of 20% or greater, with some of the largest increases reported from Saint Pierre and Miquelon (298 vs 52 new cases, +473%), Curacao (375 vs 102 new cases, +268%) and Mexico (22 418 vs 11 193 new cases, +100%). The highest numbers of new cases were reported from Brazil (267 998 new cases; 126.1 new cases per 100 000; -19%), the United States of America (212 751 new cases; 64.3 new cases per 100 000; -16%), and Chile (95 205 new cases; 498.0 new cases per 100 000; -19%).

The highest numbers of new deaths were reported from the United States of America (3612 new deaths; 1.1 new deaths per 100 000; -58%), Brazil (2242 new deaths; 1.1 new deaths per 100 000; -32%), and Mexico (829 new deaths; <1 new death per 100 000; +156%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region continued to report a decrease in new weekly cases with over 74 000 new cases, a 41% decrease as compared to the previous week. However, Jordan reported an increase in new weekly cases of 20% or greater (25 502 vs 16 449 new cases; +55%). The highest numbers of new cases were reported from Jordan (25 502 new cases; 249.9 new cases per 100 000; +55%), the Islamic Republic of Iran (19 454 new cases; 23.2 new cases per 100 000; -45%), and Bahrain (7594 new cases; 446.3 new cases per 100 000; -31%).

In the past week, the Region reported 1000 new deaths, a 38% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Islamic Republic of Iran (719 new deaths; <1 new death per 100 000; -34%), Jordan (77 new deaths; <1 new deaths per 100 000; +133%), and Lebanon (43 new deaths; <1 new deaths per 100 000; -26%).

Updates from the [Eastern Mediterranean Region](#)

European Region

Following the increase reported during the week of 7 through 13 March 2022, the number of new weekly cases appears to have stabilized in the European Region (<1%) with over 5.2 million new cases reported. Ten countries (18%) in the Region reported increases in new cases of 20% or greater, with the largest observed in Gibraltar (471 vs 231 new cases; +104%), Isle of Man (1814 vs 903 new cases; +101%), Malta (1628 vs 887 new cases; +84%) and Guernsey (2077 vs 1196 new cases; +74%)

The number of new deaths has continued to decrease in the Region, with over 13 000 new deaths reported this week, an 18% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (3681 new deaths; 2.5 new deaths per 100 000; -19%), Germany (1345 new deaths; 1.6 new deaths per 100 000; -8%), and Italy (910 new deaths; 1.5 new deaths per 100 000; -9%)

Updates from the [European Region](#)

South-East Asia Region

The decreasing trend observed in the South-East Asia Region since the end of January 2022 continues, with over 269 000 new cases reported, a 23% decrease as compared to the previous week. One country in the Region, reported an increase of 20% or greater in the past week: Bhutan (4384 vs 2822 new cases; +55%). The highest numbers of new cases were reported from Thailand (169 144 new cases; 242.3 new cases per 100 000; +7%), Indonesia (71 988 new cases; 26.3 new cases per 100 000; -49% decrease), and India (16 850 new cases; 1.2 new cases per 100 000; -40%).

Regionally, the number of new weekly deaths continues to decline, with just under 2800 new deaths reported, an 18% decrease as compared to the previous week. The highest numbers of new deaths were reported from Indonesia (1572 new deaths; <1 new death per 100 000; -21%), India (629 new deaths; <1 new death per 100 000; -23%), and Thailand (537 new deaths; <1 new death per 100 000; +13%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Consistent with the increasing trend observed since the end of December 2021, the Western Pacific Region reported an increase of 21% in the number of new weekly cases as compared to the previous week, with over 6 million new cases. Ten (44%) countries in the Region reported an increase of 20% or greater in the past week, with the largest increases observed in Lao People's Democratic Republic (6449 vs 1538 new cases; +319%), Australia (513 388 vs 196 803 new cases; +161%), American Samoa (623 vs 247 new cases; +152%), Vanuatu (352 vs 146 new cases; +141%) and Fiji (148 vs 63 new cases; +135%).

The number of new weekly deaths also continued to increase, with just under 7000 new deaths reported, a 5% increase as compared to the previous week. The highest numbers of new deaths were reported from the Republic of Korea (2033 new deaths; 4.0 new deaths per 100 000; +41%), China (1921 new deaths; <1 new death per 100 000; -2%), and Japan (1016 new deaths; <1 new death per 100 000; -18%).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition, highlights include the following:

- Rallying to combat COVID-19 rumours in the Democratic Republic of the Congo through a rumour alert and refutation system
- WHO recommends the Kingdom of Saudi Arabia's public health laboratory for recognition as a national influenza centre
- WHO and Ministry of Health Zambia scale-up COVID-19 response and continuity of health services through the support of the Act-A Health Systems Connector
- WHO/Europe holds a workshop on data analysis and information management for emergency response for Azerbaijan through the Emergency Response Information Management System (ERIMS) initiative
- Lao People's Democratic Republic Ministry of Health and WHO prepare local media for potential Omicron surge
- The Plurinational State of Bolivia leverages influenza capacities for COVID-19 response
- WHO builds a Global Health Facilities Database: Leveraging insights from COVID-19 to ensure better access to primary healthcare and Universal Health Coverage (UHC)
- Updates from the UN Crisis Management Team (UNCMT)
- Measuring the impact of online COVID-19 vaccine training courses
- Operations Support and Logistics
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

*Newly reported in this update. “●” indicates that information for this variant was received by WHO from official sources. “○” indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information becomes available. **Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 3. Methods for Figures 5 and 6

Figures include fourteen studies from the Czech Republic, Denmark, Finland, Israel, Qatar, South Africa, the United Kingdom, and the United States of America evaluating the VE against the Omicron variant, and 31 studies of the VE against the Delta variant from various countries from the European Region, Region of the Americas, and South-East Asia Region as well as Qatar and Thailand.

VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when either Delta or Omicron was the predominant circulating variant. Estimates were included if they were of laboratory-confirmed cases of the Omicron or Delta variant. In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.

For the primary series VE, estimates are only included in the plot for studies that report VE for more than one time period.

Annex 4. Summary of primary series vaccine performance against Variants of Concern (VE data as of 17 March 2022; Neutralization data as of 14 March 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺								Vaccines without WHO EUL ⁺	
	AstraZeneca- Vaxzevria/ SII - Covishield	Beijing CNBG- BBIBP-CorV	Bharat-Covaxin	Janssen- Ad26.COV 2.S	Moderna- mRNA-1273	Novavax- Nuvaxovid/ SII - Covavax	Pfizer BioNTech- Comirnaty	Sinovac- CoronaVac	Anhui ZL- Recombinant	Gamaleya- Sputnik V

Neutralization	↓↓↓ ₇	↔to↓↓↓ ₃	↓↓ ₁	↔to↓↓↓ ₃	↓↓↓ ₁₇	-	↓↓↓ ₃₇	↓↓to↓↓↓ ₄	-	↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in the study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Annex 4 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than four months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (seven days and over after the final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (where a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., >90%).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected more than seven days and less than six months after complete vaccination and that use an ancestral strain as the reference are included in Annex 4.

COVID-19 Weekly Epidemiological Update

Edition 83, published 15 March 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: Contact tracing and quarantine in the context of the Omicron SARS-CoV-2 variant: interim guidance](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 13 March 2022

After a consistent decrease since the end of January 2022, the number of new weekly cases increased by 8% during the week of 7 through 13 March 2022. The number of new deaths continued a decreasing trend (-17% as compared to the previous week) (Figure 1). Across the six WHO regions, over 11 million new cases and just over 43 000 new deaths were reported (Table 1). As of 13 March 2022, over 455 million confirmed cases and over 6 million deaths have been reported globally.

At the regional level, the Western Pacific Region, the African Region and the European Region reported increases in new weekly cases of 29%, 12% and 2%, respectively, as compared to the previous week; while decreases were reported by the Eastern Mediterranean Region (-24%), the South-East Asia Region (-21%) and the Region of the Americas (-20%).

These trends should be interpreted with caution as several countries are progressively changing their testing strategies, resulting in lower overall numbers of tests performed and consequently numbers of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 13 March 2022**

**See [Annex 2: Data, table, and figure notes](#)

The highest numbers of new cases were reported from the Republic of Korea (2 100 171 new cases; +44%), Viet Nam (1 670 627 new cases; +65%), Germany (1 350 362 new cases; +22%), Netherlands (475 290 new cases; +42%), and France (419 632 new cases; +20%).

The highest numbers of new deaths were reported from the United States of America (9078 new deaths; -13%), the Russian Federation (4530 new cases; -15%), Brazil (3301 new cases; -15%), Indonesia (1994 new cases; -5%) and China (1955 new deaths; +63%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 13 March 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Western Pacific	5 022 507 (44%)	29%	32 460 327 (7%)	6 639 (15%)	12%	193 740 (3%)
Europe	4 985 405 (44%)	2%	187 814 829 (41%)	14 985 (35%)	-23%	1 904 095 (32%)
Americas	887 162 (8%)	-20%	148 915 745 (33%)	16 093 (37%)	-15%	2 663 786 (44%)
South-East Asia	348 330 (3%)	-21%	56 470 189 (12%)	3 397 (8%)	-15%	769 025 (13%)
Eastern Mediterranean	126 257 (1%)	-24%	21 416 619 (5%)	1 694 (4%)	-49%	338 192 (6%)
Africa	38 053 (0%)	12%	8 486 757 (2%)	289 (1%)	-41%	170 589 (3%)
Global	11 407 714 (100%)	8%	455 565 230 (100%)	43 097 (100%)	-17%	6 039 440 (100%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the WHO Tracking SARS-CoV-2 variants website. National authorities may choose to designate other variants and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the global dominance of the Omicron variant. Delta remains the only other VOC with reported circulation at non-negligible levels. Among the 430 487 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 429 994 (99.9%) were Omicron and 400 (0.1%) were Delta. To note, the global distribution of VOCs should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Designation of SARS-CoV-2 VOCs as currently and previously circulating VOCs

During the last six months, a significant decline in the circulation of the **VOCs Alpha, Beta and Gamma** has been observed in all six WHO regions. Over the past 90 days, few to no sequences of these variants have been reported. The [WHO Technical Advisory Group on SARS-CoV-2 Virus Evolution \(TAG-VE\)](#) convened on 7 March 2022 to discuss the classification of these variants. While the classification of VOCs and VOIs remains unchanged, VOCs and VOIs will further be designated as either '**currently circulating**' or '**previously circulating**' depending on current epidemiological trends. On 9 March 2022, on the advice of the TAG-VE, WHO designated Alpha, Beta and Gamma as 'previously circulating VOCs' and Delta and Omicron as 'currently circulating VOCs'.

Once a variant has been classified by WHO as a VOC using an assessment based on several criteria ([WHO Tracking SARS-CoV-2 variants website, see list of criteria](#)), it remains a VOC. Low circulation of a VOC does not alter the concerning characteristics of the virus; its initial phenotypic characteristics remain unchanged. Given the uncertainty regarding the existence and low circulation of any of these VOCs in regions with limited sampling and sequencing capacity, all VOCs should continue to be monitored within the framework of representative community sampling and sequencing.

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 10 February to 11 March 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 44 countries submitted a total of 100 sequences and above on GISAID.10 February to 11 March 2022.

Designation of SARS-CoV-2 VOIs Lambda and Mu as previously circulating VOIs

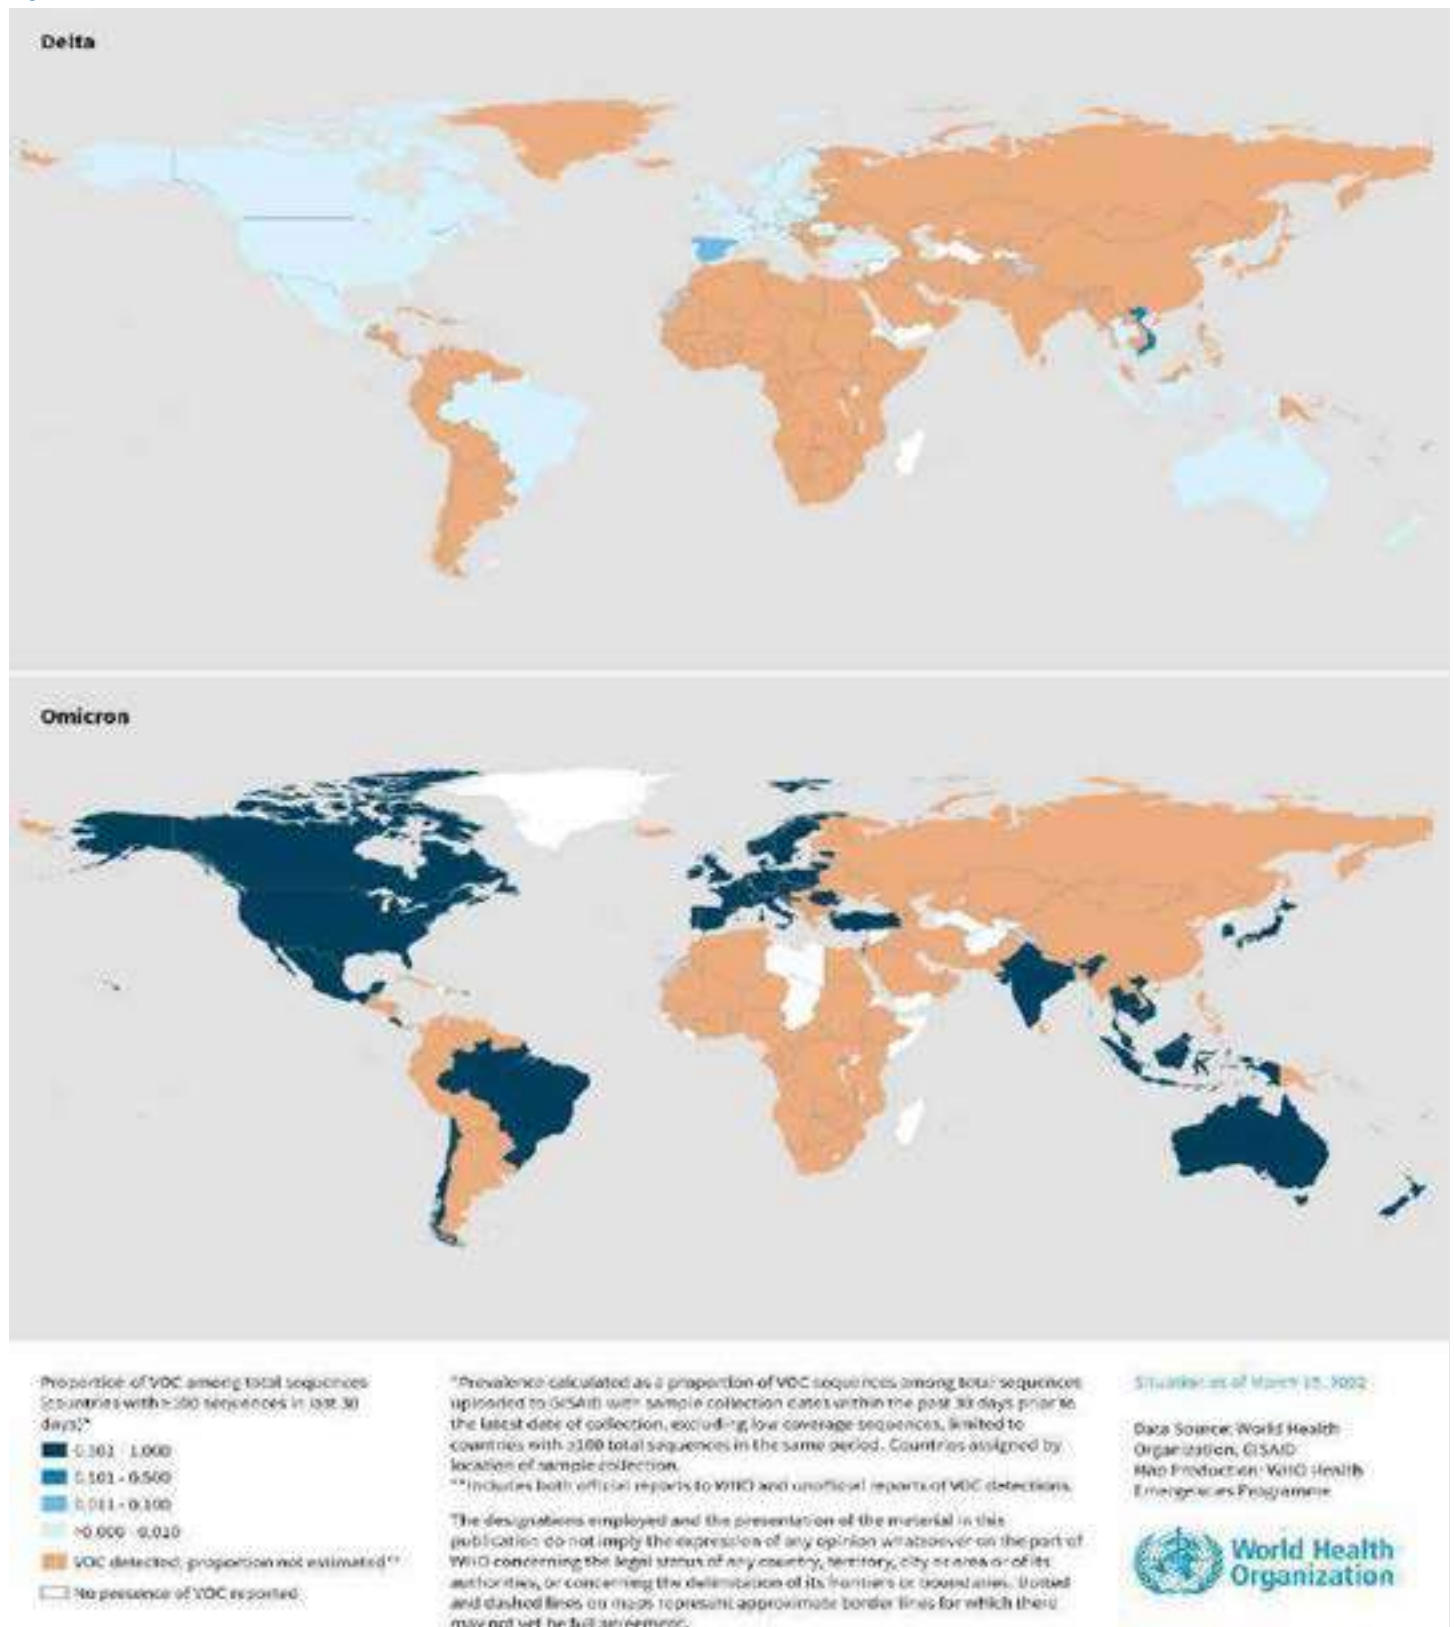

On 9 March 2022, Lambda, first detected in Peru in December 2020, and Mu, first detected in Colombia in January 2021, were designated as ‘previously circulating VOIs’. Their prevalence has declined significantly over the last year, with no circulation reported during the past 90 days in any of the six WHO regions.

The actions required by Member States remain the same whether the VOC or VOI is further categorized as currently or previously circulating, for more details see the [WHO Tracking SARS-CoV-2 variants website](#). Member States should continue to monitor SARS-CoV-2 variants, including current and previously circulating VOCs and VOIs, and flag any observed upsurge of cases linked to these variants. The designation from currently circulating VOC or VOI to previously circulating VOC or VOI reflects the declined circulation of the variant but does not exclude the possibility of a future upsurge of this variant.

Special Focus: Contact tracing and quarantine in the context of the Omicron SARS-CoV-2 variant: interim guidance

With the emergence of the Omicron variant and the significant surge in SARSCoV-2 infections, many countries experienced overwhelmed public health capacities to effectively conduct comprehensive contact tracing as part of the COVID-19 response. The increasing number of contacts needing quarantine also risked leading to the disruption of essential societal services, including health services.

In light of these challenges and with the increasing levels of population immunity, both from past infection and vaccination, on 17 February 2022 WHO released [updated interim guidance](#) for contact tracing and quarantine in the context of the Omicron variant.¹ This document was produced in collaboration with the Contact Tracing Guideline Development Group and the Infection Prevention and Control Guideline Development Group. Both groups of external experts, together with WHO technical experts, reviewed the available evidence on Omicron transmission dynamics and the persistence of immunity. The guidance document recommends a risk-based approach that focuses on reducing the morbidity and mortality from infection rather than attempting to break all chains of transmission when the number of cases is overwhelming capacities to respond.

Prioritizing contacts to follow up

In situations where contact tracing and public health capacities are overstretched, and there is a risk of essential societal service disruption, prioritization for contact tracing should be given to:

- contacts at highest risk of getting infected and those, such as health and care workers, who are at highest risk of spreading the virus to vulnerable people – particularly those working in nursing homes, long-term care facilities and hospitals; and other frontline essential workers.
- contacts at highest risk for developing severe disease, such as people with comorbidities, those who are immunosuppressed, the elderly, and adults who are unvaccinated or partially-vaccinated with no known prior SARS-CoV-2 infection.

In these situations, there is a particular added value in educating and encouraging cases to notify their own contacts, and where possible, using automated contact notification technologies (e.g., digital contact tracing apps) to quickly reach and provide guidance to multiple contacts simultaneously.

Quarantine in a high COVID-19 incidence area

The document offers guidance on the possibility to shorten the quarantine period from 14 to seven days, provided a negative PCR or an antigen rapid test result is obtained on day seven. In the case of overstretched testing capacity, authorities can shorten the quarantine period from 14 to 10 days, provided that contacts do not have any COVID-19 symptoms. Both options present some risk of further transmission, but in a situation of high incidence and considering the disruption of essential services, the benefits in doing so may outweigh the risks. If the quarantine is shortened, WHO recommends that contacts wear a well-fitted medical mask, monitor symptoms and avoid contact with vulnerable people for the remained 14-day period.

Vaccinated and previously infected contacts

The available evidence on vaccine effectiveness suggests that protection against infection wanes over time. The likelihood of infection with the Omicron variant is reduced within 90 days after the primary series or booster vaccination. Therefore, contacts vaccinated within the last 90 days can be considered a lower priority for contact tracing and may undergo a shorter quarantine. Similarly, infection-derived immunity wanes over time, but it is

expected to persist at least 90 days from infection. Thus, contacts infected within the last 90 days can also be considered a lower priority for contact tracing and may undergo a shorter quarantine.

Conclusions

As per the experience with the Omicron variant, countries may need to take policy decisions before the evidence on an emerging future variant is consolidated. In this case, WHO advises Member States to consider applying risk-based approaches that take into account different aspects of the epidemic, such as the intensity of transmission, the severity of disease associated with circulating variants, the levels of population immunity from past infection and vaccination, the capacity to track and trace contacts, access to rapid and accurate SARS-CoV-2 diagnostics, the capacity to assess the risk of exposure in health and care workers and other essential services personnel, and the overall pre-existing capacities of the health care system.

Any interruption of contact tracing activities or shortening of the duration of quarantine will increase the risk of onward transmission and this must be weighed against healthcare capacity, population immunity against the Omicron variant, and other health and socioeconomic priorities.

WHO regional overviews

Epidemiological week 7-13 March 2022**

African Region

The African Region reported over 38 000 new weekly cases, an 8% increase as compared to the previous week. This followed on from a declining trend observed since January 2022. Eleven (22%) countries in the Region reported an increase of over 20% in cases, with some of the highest proportional increases observed in Mauritius (11566 vs 4133 new cases; +180%), Nigeria (308 vs 136 new cases; +126%), and the Democratic Republic of Congo (190 vs 136 new cases; +40%). The highest numbers of new cases were reported from Mauritius (11 566 new cases; 909.4 new cases per 100 000 population; +180%), South Africa (10 360 new cases; 17.5 new cases per 100 000; -7%), and Réunion (8019 new cases; 895.7 new cases per 100 000; -20%).

The number of new weekly deaths in the Region decreased by 41% as compared to the previous week, with just under 300 new deaths reported. The highest numbers of new deaths were reported from South Africa (169 new deaths; <1 new death per 100 000 population; -52%), Mauritius (30 new deaths; 2.4 new deaths per 100 000; +233%), and Zimbabwe (17 new deaths; <1 new death per 100 000; +325%).

Updates from the [African Region](#)

Region of the Americas

With over 887 000 new weekly cases reported, the Region of the Americas continued to experience a decreasing trend (20% decrease as compared to the previous week). However, nine (16%) countries in the Region reported increases in new cases of 20% or greater, with the greatest increases observed in the islands of Saint Pierre and Miquelon (52 vs 8 new cases; +550%), Martinique (13686 vs 3216 new cases; +326%), and the United States Virgin Islands (130 vs 31 new cases; +319%). The highest numbers of new cases were reported from Brazil (331 315 new cases; 155.9 new cases per 100 000; -16%), the United States of America (247 936 new cases; 74.9 new cases per 100 000; -28%), and Chile (118 141 new cases; 618.0 new cases per 100 000; -23%).

The Region reported over 16 000 new deaths this week, a 15% decrease as compared to the previous week. The highest numbers of new deaths were reported from the United States of America (9078 new deaths; 2.7 new deaths per 100 000; -13%), Brazil (3301 new deaths; 1.6 new deaths per 100 000; -15%), and Mexico (976 new deaths; <1 new death per 100 000; +69%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline following a peak reached in early February 2022. Over 126 000 new weekly cases were reported, a 24% decrease as compared to the previous week. However, two countries in the Region have reported increases in new cases of 20% or greater: Tunisia (24061 vs 9454 new cases; +155%) and Afghanistan (1715 vs 1167 new cases; +47%). The highest numbers of new cases were reported from the Islamic Republic of Iran (35 457 new cases; 42.2 new cases per 100 000; -34%), Tunisia (24 061 new cases; 203.6 new cases per 100 000; +155%), and Jordan (16 449 new cases; 161.2 new cases per 100 000; -22%).

The number of new weekly deaths decreased by 49% in the Region when compared to the previous week, with just under 1700 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (1084 new deaths; 1.3 new deaths per 100 000; -20%), Tunisia (124 new deaths; 1.0 new deaths per 100 000; -44%), and Egypt (105 new deaths; <1 new death per 100 000; -42%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After a decreasing trend observed since the end of January 2022, the European Region reported a slight increase (+2%) in the number of new weekly cases as compared to the previous week, with just under 5 million new cases. Twelve countries (20%) in the Region reported increases in new cases of 20% or greater, with the largest observed in Monaco (240 vs 162 new cases; +48%), Malta (887 vs 621 new cases; +43%) and the Netherlands (475 290 vs 335 283 new cases; +42%). The highest numbers of new cases were reported from Germany (1 350 362 new cases; 1623.7 new cases per 100 000; +22%), the Netherlands (475 290 new cases; 2730.4 new cases per 100 000; +42%), and France (419 632 new cases; 645.2 new cases per 100 000; +20%).

The number of new deaths has continued to decrease in the Region, with just under 15 000 new deaths reported this week, a 23% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (4530 new deaths; 3.1 new deaths per 100 000; -15%), Germany (1469 new deaths; 1.8 new deaths per 100 000; +3%), and Italy (1000 new deaths; 1.7 new deaths per 100 000; -27%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 348 000 new weekly cases, a 21% decline as compared to the previous week, continuing the decreasing trend observed since mid-January 2022. The highest numbers of new cases were reported from Thailand (158 130 new cases; 226.5 new cases per 100 000; a +1%), Indonesia (141 770 new cases; 51.8 new cases per 100 000; -32%), and India (28 038 new cases; 2.0 new cases per 100 000; -40%).

Regionally, the number of new weekly deaths declined, with just under 3400 new deaths reported, a 15% decrease as compared to the previous week. The highest numbers of new deaths were reported from Indonesia (1994 new deaths; <1 new death per 100 000; -5%), India (814 new deaths; <1 new death per 100 000; -38%), and Thailand (474 new deaths; <1 new death per 100 000; +38%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Consistent with the increasing trend observed since the end of December 2021, the Western Pacific Region reported an increase of 29% in the number of new weekly cases as compared to the previous week, with over 5 million new cases. Seven (23%) countries in the region reported an increase of 20% or greater in the past week, with the largest increases observed in Vanuatu (146 vs 3 new cases; +4767%), Tonga (685 vs 280 new cases; +145%), and American Samoa (257 vs 112 new cases; +121%). The highest numbers of new cases were reported from the Republic of Korea (2 100 171 new cases; 4096.4 new cases per 100 000; +44%), Viet Nam (1 670 627 new cases; 1716.3 new cases per 100 000; +65%), and Japan (382 278 new cases; 302.3 new cases per 100 000; -16%).

The number of new weekly deaths continues to increase, with over 660 new deaths reported, a 12% increase as compared to the previous week. The highest numbers of new deaths were reported from China (1955 new deaths; <1 new death per 100 000; +63%), the Republic of Korea (1438 new deaths; 2.8 new deaths per 100 000; +42%), and Japan (1240 new deaths; 1.0 new deaths per 100 000; -18%).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition, highlights include the following:

- WHO scales-up sub-regional training on intra and after-action reviews (IAR/AARs) for COVID-19 in the European Region
- Women in India lead the fight against COVID-19 in communities
- Nigeria holds its first infodemic management workshop
- Update on the joint PAHO/WHO-ITU initiative in the Eastern Caribbean to leverage digital technology to promote COVID-19 vaccines
- WHO in partnership with UNICEF hands over reconstructed central drug warehouse to serve over 1 million residents in Lebanon
- WHO Information Network for Epidemics (EPI-WIN) co-developing solutions with networks
- OpenWHO COVID-19 vaccination training: Health workers' experiences in India, Indonesia, Kenya and Pakistan
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

*Newly reported in this update. “●” indicates that information for this variant was received by WHO from official sources. “○” indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information becomes available. **Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 82, published 8 March 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 6 March 2022

Globally, during the week of 28 February through 6 March 2022, the number of new COVID-19 cases and deaths continued to decline by 5% and 8% respectively, as compared to the previous week (Figure 1). Across the six WHO regions, over 10 million new cases and over 52 000 new deaths were reported (Table 1). As of 6 March 2022, over 433 million confirmed cases and over 5.9 million deaths have been reported globally.

At the regional level, while the Western Pacific Region continued to report an increase (+46%) in the number of new weekly cases, all other regions reported decreases: the Eastern Mediterranean Region (-46%), the African Region (-40%), the South-East Asia Region (-31%), the Region of the Americas (-24%), and the European Region (-18%). The number of new weekly deaths increased in the Western Pacific Region (+29%) and remained stable in the Eastern Mediterranean Region (+2%), while decreases were reported by the African Region (-39%), the European Region (-15%), the Region of the Americas (-9%) and the South-East Asia Region (-3%). These trends should be interpreted with caution as several countries are progressively adopting targeted testing strategies, resulting in lower overall numbers of tests performed and consequently of cases detected.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 6 March 2022**

**See [Annex 2: Data, table, and figure notes](#)

The highest numbers of new cases were reported from the Republic of Korea (1 461 431 new cases; +42%), Germany (1 108 231 new cases; -1%), Viet Nam (1 013 343 new cases; +112%), the Russian Federation (650 540 new cases; -29%), and Japan (452 763 new cases; +4%).

The highest number of new deaths were reported from the United States of America (10 579 new deaths; -9%), Russian Federation (5354 new deaths; -1%), Brazil (3865 new deaths; -11%), Indonesia (2099 new deaths, +23%), and Japan (1519 new deaths; -7%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the global dominance of the Omicron variant. Delta remains the only other named variant with significant reported circulation. Among the 428 417 sequences uploaded to [GISAID](#) with specimen collection date in the last 30 days,ⁱ 427 152 (99.7%) were Omicron and 580 (0.1%) were Delta. For all countries/areas/territories with 100 or more sequences uploaded to GISAID within the last 30 days, Omicron remains the dominant variant.

Among Omicron descendent lineages reported within the last 30 daysⁱ, BA.1.1 is the predominant sub-variant, accounting for 187 058 sequences (41%); BA.2 accounts for 156 014 sequences (34.2%); BA.1 accounts for 112 655 sequences (24.7%); and BA.3 accounts for 101 sequences (<1%).ⁱⁱ To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Both the Technical Advisory Group on SARS-CoV-2 Virus Evolution (TAG-VE) and WHO are aware of reports on recombinant variants, both recombinants of Delta and Omicron, as well as recombinants of BA.1 and BA.2. Recombination is a natural phenomenon and can be regarded as an expected mutational event. The same monitoring and assessment process is applied to these recombinants, after verification and exclusion of potential contamination or co-infection, as for any other emerging variant. Current epidemiological and sequencing information for these recombinants do not indicate any sign of rapid transmission or a change in clinical severity. Only a few clusters have been reported to date and show very low to almost undetectable levels of transmission to contacts. No recombinant variant has been given a Pango lineage name.

The Omicron variant

Differences in the characteristics of VOCs

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last update on 15 February 2022](#), there have been several new publications on the phenotypic characteristics of VOCs, including literature on Omicron (Table 2). Some of these studies have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

ⁱ Includes sequences submitted to GISAID with sample collected dates from 4 February to 5 March 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 46 countries submitted a total of 100 sequences and above on GISAID.

ⁱⁱ Please note that uploaded GISAID data for the maps and the global epidemiological reporting are slightly different in absolute numbers as compared to Omicron descendent lineage sequence data. The latter is taken from the manual GISAID data availability

Table 2: Summary of current evidence on Omicron

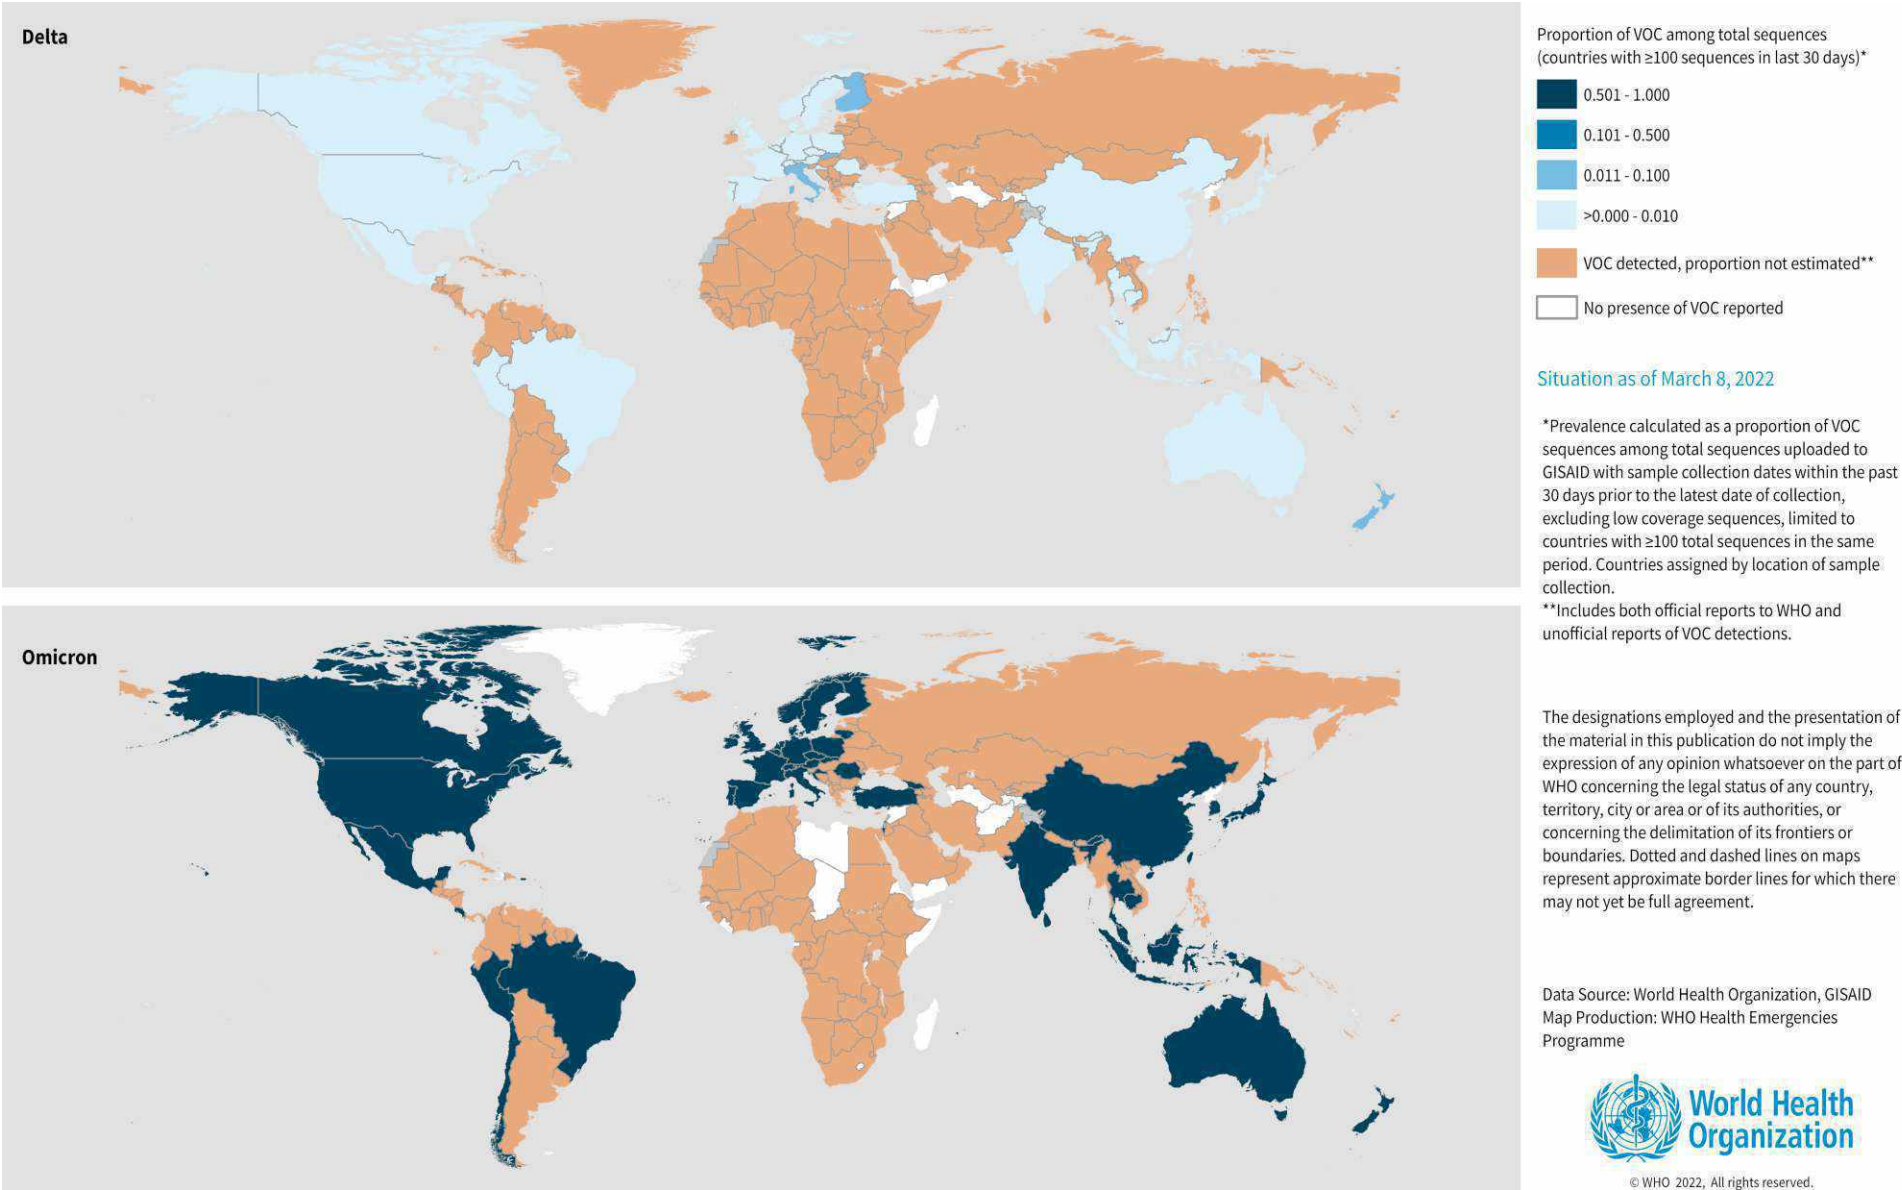

Domain	Indicator	Main results
Epidemiology	Impact on disease prevalence/incidence	<p>There has been a decreasing trend in the number of COVID-19 cases reported globally. When compared to the previous week, the number of new COVID-19 cases decreased by 5% during the week of 28 February through 6 March 2022. The Western Pacific Region reported a 46% increase in the number of new cases while all other regions reported decreases. It is important to note that the decrease in the number of reported cases might be partly due to changes in testing policies in a number of countries, resulting in a reduction in testing and consequently of cases detected.</p> <p>The Omicron variant is the dominant circulating variant globally, representing 99.7% of samples collected from 4 February to 5 March 2022, while the Delta variant represents 0.1%.</p>
	Impact on transmission	<p>An updated analysis of GISAID data¹ shows similar results to the previous iteration, with Omicron still having a growth rate advantage over Delta in all countries with sufficient sequence data available up to 3 March 2022, translating to a pooled mean transmission advantage (i.e. relative difference in effective reproduction numbers) of 75% (95% Confidence Interval: 64%-93%) across epidemiological contexts under the assumption of an unchanged generation time (i.e. duration between the time a person gets infected to the time that person infects another person). However, evidence for a reduced generation time of Omicron suggests the transmission advantage may be lower; for a 20% shorter generation time, the estimated pooled mean transmission advantage of Omicron over Delta is 64% (95% CI: 59%-80%). The same analysis demonstrates a growth rate advantage of the Omicron Pango lineage BA.2 over the Pango lineage BA.1, with a pooled mean transmission advantage of 56% (95% CI: 42%-72%) under the assumption of an unchanged generation time. These estimates are stabilising as the number of BA.1/BA.2/BA.3 sequences per country are increasing and data become available from more countries.</p> <p>In the United Kingdom², BA.2 has been found to have a higher growth rate compared to BA.1 (82.7 %; range: 54%-100%) and higher secondary attack rates for household (14.3%; 95%CI: 13.6%-14.9% vs. 11.4%; 95%CI: 11.2%-11.5%) and non-household (6.1%; 95%CI:5.0%-7.2% vs. 4.6%; 95%CI: 4.5%-4.8%) contacts.</p>
	Impact on disease severity	<p>Omicron has consistently been found to have lower severity when compared to Delta across different settings. There was no difference in the risk of hospitalisation (HR=0.87; 95% CI: 0.75-1.00) between patients infected with BA.1 and BA.2 in the United Kingdom³⁷.² Similarly, the odds of hospitalisation among SARS-CoV-2-infected patients did not differ between those with BA.1 and BA.2 (aOR=0.96; 95%CI: 0.85-1.09) in South Africa.³</p>
Immune response	Impact on reinfection	<p>Higher rates of reinfection have been reported for the Omicron variant than among individuals previously infected with other SARS-CoV-2 variants. Recent data from Qatar suggest that previous infection with one of the Omicron Pango lineages may confer protection against infection with other Omicron Pango lineages: 94.9% (95% CI: 88.4-97.8%) protection against BA.2 following infection with BA.1 and 85.6% (95% CI: 77.4-90.9%) protection against BA.1 following infection with BA.2 over a period of two months of follow-up.⁴ The duration of this protection is not currently known.</p>
	Impact on vaccination	<p>For further information, see the section <i>Interpretation of the results of the VE for the Omicron variant</i>. Results of vaccine effectiveness (VE) studies should be interpreted with caution because estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines).</p>

	Impact on antibody responses	An analysis of neutralization data from 23 laboratories found a 20-fold reduction in neutralization associated with the Omicron variant. ⁵ These findings are consistent with results of recent studies that reported lower neutralising antibody titers to BA.1 and BA.2 compared to wild-type SARS-CoV-2, and similar responses for BA.1 and BA.2. ⁸ Another recent study found similar non-neutralising antibody responses to BA.1 and BA.2 in vaccinated individuals. ⁷ Overall, these results indicate similar humoral responses for BA.1 and BA.2.
Diagnostic tools	Impact on PCR assays	There is no recent evidence on the impact of Omicron on PCR assays. The BA.2 lineage is the only descendant variant of Omicron that lacks the 69-70 deletion responsible for S-gene target failure. Evaluation of PCR tests for SARS-CoV-2 that include multiple gene targets revealed limited impact of the Omicron variant on the diagnostic test accuracy of these assays. ⁸
	Impact on Rapid Diagnostic tests	Preliminary data showed contradictory results on the diagnostic performance of Ag-RDTs on Omicron compared to Delta, the wild-type virus or other VOCs. ^{12,13} While some studies have shown reduced sensitivity of Ag-RDTs ^{9,10} a recent study from the United States of America reported comparable sensitivity of three Ag-RDT tests for Omicron and Delta. ¹¹
Impact on treatment	Impact on antivirals	Preliminary data have shown no difference in the effectiveness of antiviral agents against the Omicron variant. ^{12–14}
	Impact on biologicals	Initially, studies on the effectiveness of monoclonal antibodies for treating patients with Omicron reported conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduction in effectiveness of other monoclonal antibodies. ^{15–19} However, additional preclinical evidence shows reduced neutralizing activity of sotrovimab against the BA.2 lineage and lack of efficacy of casirivimab-imdevimab against the BA.1 lineage. ²⁰
	Other treatment options	There is no evidence to suggest a reduction in the effectiveness of Interleukin-6 receptor blockers and corticosteroids in the management of patients with severe and critical disease.

Figure 4: Prevalence of variants of concern (VOCs) Delta and Omicron in the last 30 days, data as of 8 March 2022

See also [Annex 1](#) for reported VOC detections by country/territory/area

Figure 5. Vaccine effectiveness (VE) of primary series and booster vaccination against the Delta variant of concern

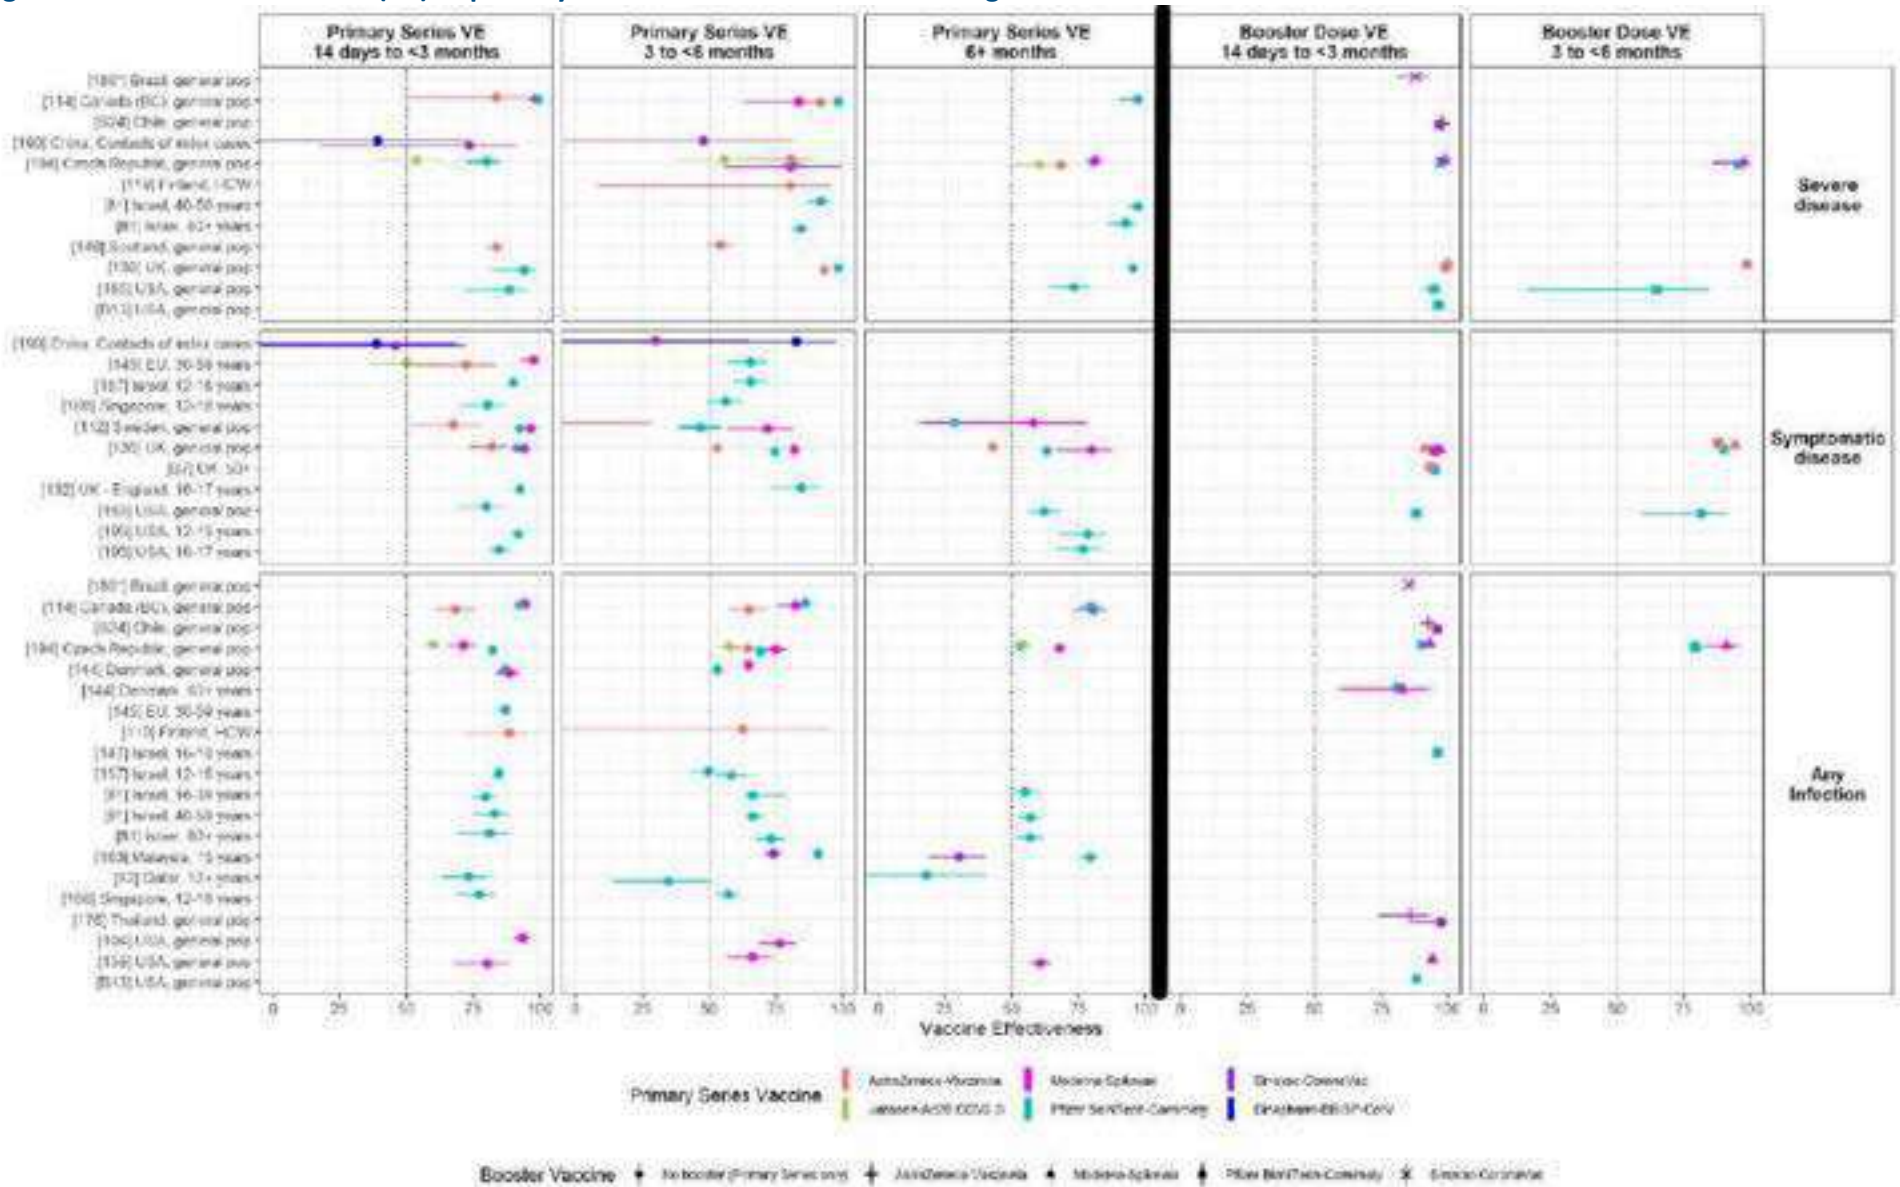

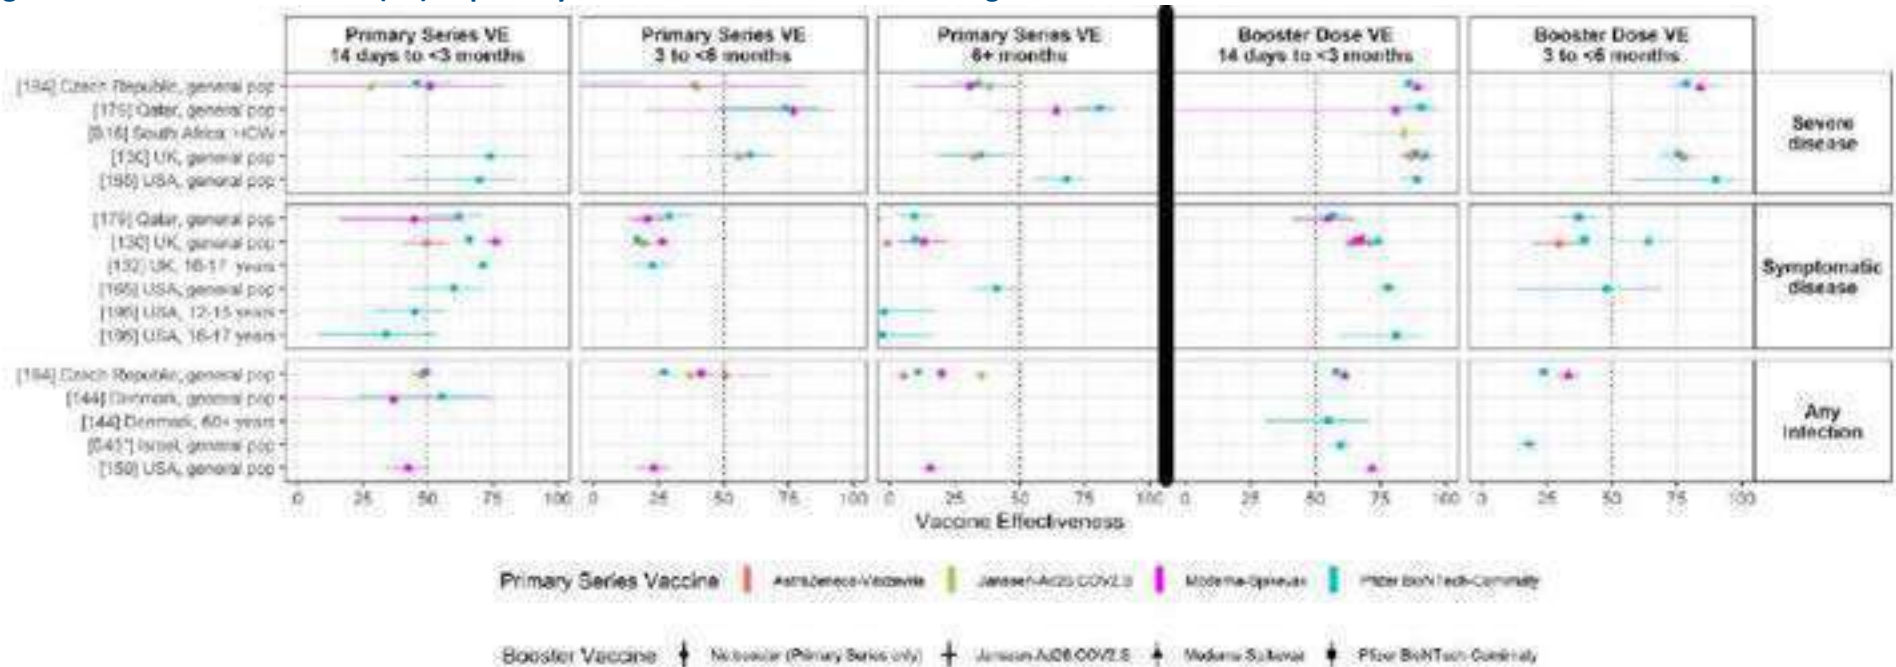

Figure 6. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant

*Indicates booster dose vaccine effectiveness evaluated using persons completing primary series as reference group, rather than unvaccinated persons. Abbreviations: pop=population; HCW=healthcare workers; EU=European Union. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the [summary table](https://view-hub.org) of VE effectiveness studies on view-hub.org (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for AstraZeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes hospitalization and pneumonia. Symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots are provided in Annex 3. Note, three negative point estimates for the primary series are not shown in the Omicron plot: Moderna-Spikevax VE against symptomatic disease at 6+ months (reference 179) as well as Moderna-Spikevax and Pfizer BioNTech-Comirnaty VE against infection at 3-6 months (reference 144); one negative point estimate for primary series is not shown in the Delta plot: AstraZeneca-Vaxzevria VE against Delta symptomatic disease (reference 112) with 95% CIs crossing 0 is not fully visible in the plot.

Figures 5 and 6 summarize the impact of the Delta and Omicron variants, respectively, on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Since the last update, six new studies (of which three not peer-reviewed) have been added to the figures.^{21–26} One study provided new Omicron VE data on AstraZeneca-Vaxzevria vaccine, one on Janssen-Ad26.COV2.S vaccine, one on Moderna-Spikevax vaccine, and four on Pfizer BioNTech-Comirnaty vaccine. Of note, recently published studies from China and Thailand contributed data on VE of two inactivated vaccines, Beijing CNBG - BBIBP-CorV and Sinovac-CoronaVac, against the Delta variant. Additional information on vaccine performance against VOCs can also be found in Annex 4.

Interpretation of the results of VE studies for the Delta variant

Most of the evidence to date suggests that the effectiveness of mRNA vaccines (Pfizer BioNTech-Comirnaty and Moderna-Spikevax) remains high against *severe disease* associated with Delta variant infection at six or more months after the primary series, with five of six studies reporting VE estimates of >80% and one study reporting a VE of 74% at six months or more. One study reported VE estimates against *severe disease* of 61% and 68% for Janssen-Ad26.COV2.S and AstraZeneca-Vaxzevria vaccines, respectively. Four studies report high VE (≥80%) of the AstraZeneca-Vaxzevria vaccine three to six months following the primary series, while one study reports a lower VE (54%) after six months as compared to the first three months (84%). An additional study showed VE of AstraZeneca-Vaxzevria vaccine against *severe disease* decreased from 80% at three to less than six months after completion of the primary series, to 68% at six or more months after the second dose. One study providing evidence of protection against *severe disease* due to Delta variant for Janssen-Ad26.COV2, showed that the VE stayed relatively constant at 54-61% up to six months after the primary series of vaccination. One new study showed that the VE of Sinovac-CoronaVac against the development of pneumonia (classified as severe COVID-19 in Figure 5) among close contacts of Delta index cases decreased from 74% in the first three months following completion of the primary series to 47% from three to six months.

VE estimates against *symptomatic disease* and *infection* range from 71-96% following the primary series of one of the two mRNA vaccines from 14 days up to three months after vaccination, and from 68-88% and 50-60% following the primary series of the AstraZeneca-Vaxzevria and Janssen-Ad26.COV2.S vaccines, respectively, during the same time period. There is consistent evidence of decreasing VE against *symptomatic disease* and *infection* over time following the primary series for all of the vaccines for which data are available. Despite this, most of the evidence still suggests VE estimates of >50% (59-80%) at six months or more following either mRNA vaccine, with two estimates falling below 50%. Four of the five studies evaluating the AstraZeneca-Vaxzevria vaccine also showed a VE >50% (54-65%) at three to six months, though in one of these studies, the VE decreased to 43% at six or more months following the primary series. The VE of Janssen-Ad26.COV2.S vaccine ranged from 50-60% up to six months following vaccination (two studies). One study from Malaysia of Sinovac-CoronaVac vaccine reported a VE against *infection* of 74% at three to six months following the primary series, which decreased to 30% beyond six months. A second study of Sinovac-CoronaVac vaccine from China found that the VE against *symptomatic disease* among close contacts of index cases decreased from 46% at 14 days to less than three months to 30% from three to six months. This same study estimated the VE of Beijing CNBG - BBIBP-CorV vaccine against *symptomatic disease* among close contacts index cases to be 39% shortly after completion of the primary series, increasing to 82% from three to six months, though confidence intervals are wide and should be interpreted with caution.

Receipt of a booster dose of mRNA, vector-based or inactivated vaccines for which there are data available, resulted in VE estimates of ≥79% for *all outcomes* within the first three months. At three to six months following the booster dose, the VE of a Pfizer BioNTech-Comirnaty booster following Pfizer BioNTech-Comirnaty or AstraZeneca-Vaxzevria primary series, as well as the VE of three doses of Moderna-Spikevax vaccine, remained >95% against *severe disease*

in two studies conducted in the United Kingdom and the Czech Republic, but decreased from 95% to 65% with Pfizer BioNTech-Comirnaty primary series and booster in a single study conducted in the United States of America. In the same studies mentioned above from the United Kingdom and the United States of America, the VE against *symptomatic disease* at three months or more following a booster dose with an mRNA vaccine was >75% after a primary series of either the AstraZeneca-Vaxzevria or Pfizer BioNTech-Comirnaty vaccine.

Interpretation of the results of VE studies for the Omicron variant

Four studies of VE for the Omicron variant show a lower protection of the primary series COVID-19 vaccines for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed for other VOCs. Nevertheless, VE estimates against the Omicron variant remain highest against *severe disease*, and lower for *symptomatic disease and infection* outcomes. Booster doses of vaccine appear to substantially improve VE for all outcomes for all products for which data are available. However, due to short follow-up time in studies available to date, additional data are needed to characterize the duration of VE following a booster dose.

Studies from Qatar, the United Kingdom, and the United States of America report VE estimates for the Pfizer BioNTech-Comirnaty vaccine against *severe disease* due to the Omicron variant of >70% up to six months following the primary series, which remained stable after six months in the studies conducted in Qatar and the United States of America, but decreased to <50% in the study conducted in the United Kingdom. In the study from Qatar, VE of the Moderna-SpikeVax mRNA vaccine remained >70% up to and beyond six months after vaccination. In contrast, one recent study (not peer-reviewed) from the Czech Republic found lower VE (<50%) at all time points of follow-up for both mRNA vaccines, as well as the Janssen-Ad26.COV.2 vaccine. Fluctuation in VE estimates over time since vaccination in this study may be due to underlying biases in the data (e.g. low ascertainment rate), and results should be interpreted with caution. In a study from the United Kingdom, VE estimates for the AstraZeneca-Vaxzevria vaccine against *severe disease* reduced from 56% to 33% from three months or more, with relatively wide confidence intervals (see Figure 6 for details).

Early VE estimates (measured from 14 days up to three months after vaccination) of the primary series against *symptomatic disease* are generally lower than those for *severe disease*, though they remain at or above 50% for the AstraZeneca-Vaxzevria, Moderna-Spikevax, and Pfizer BioNTech-Comirnaty vaccines. Lower VE estimates for the same time period were observed in two studies, one which reported VE of 45% for the Moderna-Spikevax vaccine and another which reported VE estimates of 34% and 45% for the Pfizer BioNTech-Comirnaty vaccine for adolescents 16-17 years and 12-15 years, respectively.

VE against *infection* at 14 days up to three months after the primary series ranged from 37-55%. All available estimates against both *symptomatic disease* and *infection* measured three or more months after completion of the primary series indicate VE estimates of less than 52% for the three vaccines (Pfizer BioNTech-Comirnaty, Moderna-Spikevax and AstraZeneca-Vaxzevria).

In all the six new studies, a booster dose increased VE estimates against *severe disease* to above 75% for all vaccines for which data are available, with this effect maintained up to six months after the booster dose. A booster dose increased VE estimates against *symptomatic disease* in the first three months following vaccination substantially, by at least 37 percentage points across all vaccines, with VE estimates ranging from 55%-81%. However, VE estimates decreased to 29-64% beyond three months. VE against *infection* due to the Omicron variant in the first three months following a booster dose ranged from 55-71% and decreased to 18-33% at three to less than six months post-booster.

WHO regional overviews

Epidemiological week 28 February – 6 March 2022**

African Region

The African Region has continued to report a decrease in the number of cases since the beginning of January 2022, with just under 34 000 new cases reported this week, a 40% decrease as compared to the previous week. However, six countries in the Region (12%) reported an increase of over 20% in new weekly cases, with the largest observed in Central African Republic (95 vs 38 new cases; +150%). The highest numbers of new cases were reported from South Africa (11 181 new cases; 18.9 new cases per 100 000 population; -25%), Réunion (10 036 new cases; 1121.0 new cases per 100 000; -26%), and Mauritius (4133 new cases; 325.0 new cases per 100 000; -75%).

With over 400 new deaths reported this week, the Region observed a 39% decrease in new weekly deaths as compared to the previous week (during which a backlog of deaths was reported by South Africa following an ongoing audit exercise). The highest numbers of new deaths were reported from South Africa (352 new deaths; <1 new death per 100 000 population; -39%), Réunion (26 new deaths; 2.9 new deaths per 100 000; -30%), and Algeria (25 new deaths; <1 new deaths per 100 000; -39%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.1 million new cases, a 24% decrease as compared to the previous week, continuing the declining trend that has been observed since mid-January 2022. However, three countries have reported increases in new cases of 20% or greater, with the largest increases observed in Martinique (5569 vs 1381 new cases; +303%) and Mexico (46 765 vs 27 427 new cases; +71%). The highest numbers of new cases were reported from Brazil (395 152 new cases; 185.9 new cases per 100 000; -24%), the United States of America (343 096 new cases; 103.7 new cases per 100 000; -29%), and Chile (152 705 new cases; 798.8 new cases per 100 000; -22%).

The Region reported just under 20 000 new deaths this week, a 9% decrease as compared to the previous week. The highest numbers of new deaths were reported from the United States of America (10 579 new deaths; 3.2 new deaths per 100 000; -9%), Brazil (3865 new deaths; 1.8 new deaths per 100 000; -11%), and Mexico (1513 new deaths; 1.2 new deaths per 100 000; +49%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases declined for a third consecutive week since the peak reached in early February 2022. Over 165 000 new cases were reported this week, representing a 46% decrease as compared to the previous week. However, Somalia reported a 64% increase in new cases (87 vs 53 new cases). The highest numbers of new cases were reported from the Islamic Republic of Iran (53 363 new cases; 63.5 new cases per 100 000; -49%), Jordan (21 050 new cases; 206.3 new cases per 100 000; -63%), and Bahrain (15 781 new cases; 927.4 new cases per 100 000; -25%).

The number of new weekly deaths remained stable (+2%) when compared to the previous week's figure, with over 3300 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (1357 new deaths; 1.6 new deaths per 100 000; -15%), Sudan (956 new deaths; 2.2 new deaths per 100 000; +1012%) which shows an abnormal increase due to a backlog reporting of deaths, and Tunisia (220 new deaths; 1.9 new deaths per 100 000; -33%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region continued to report a decline in new weekly cases this week, with over 4.7 million new cases, an 18% decrease as compared to the previous week. The Region has reported a decrease in the number of new cases since a peak in late-January 2022. This week, the Region accounted for 45% of new cases reported globally. The highest numbers of new cases were reported from Germany (1 108 231 new cases; 1332.5 new cases per 100 000; similar to the previous week's figures), the Russian Federation (650 540 new cases; 445.8 new cases per 100 000; -29%), and Turkey (350 828 new cases; 416.0 new cases per 100 000; -35%).

This week, over 19 000 new deaths were reported in the Region, a 15% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (5354 new deaths; 3.7 new deaths per 100 000; similar to the previous week's figures), Germany (1424 new deaths; 1.7 new deaths per 100 000; similar to the previous week's figures), and Italy (1366 new deaths; 2.3 new deaths per 100 000; -13%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region has continued to report a decrease in the number of new cases since mid-January 2022. Over 441 000 new cases were reported in the Region this week, a 31% decrease as compared to the previous week. Although a declining trend in the number of cases was reported regionally, Bhutan reported a 23% increase as compared to the previous week (2604 vs 2116 cases). The highest numbers of new cases were reported from Indonesia (209 331 new cases; 76.5 new cases per 100 000; -39%), Thailand (157 079 new cases; 225.0 new cases per 100 000; similar to the previous week's figures), and India (46 836 new cases; 3.4 new cases per 100 000; -50%).

The number of new deaths was similar to that of the previous week, with just over 3900 new deaths reported. The highest numbers of new deaths were reported from Indonesia (2099 new deaths; <1 new death per 100 000; +23%), India (1312 new deaths; <1 new death per 100 000; -28%), and Thailand (344 new deaths; <1 new death per 100 000; +29%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported a steep increase (46%) in new weekly cases as compared to the previous week, with over 3.8 million new cases, continuing its upward trend since early January. Ten of 29 (34%) countries reported an increase of 20% or greater in the past week, including several Pacific Island countries (Cook Islands, American Samoa, Tonga, Fiji and Kiribati and New Zealand), China, and Viet Nam. The highest numbers of new cases were reported from the Republic of Korea (1 461 431 new cases; 2850.5 new cases per 100 000; +42%), Viet Nam (1 013 343 new cases; 1041.0 new cases per 100 000; +112%), and Japan (452 763 new cases; 358.0 new cases per 100 000; -4%).

The Region has reported an increase in the number of deaths for a month, with over 5900 new deaths this week, a 29% increase as compared to the previous week. The highest numbers of new deaths were reported from Japan (1519 new deaths; 1.2 new deaths per 100 000; -7%), China (1197 new deaths; <1 new death per 100 000; +296%), and the Republic of Korea (1013 new deaths; 2.0 new deaths per 100 000; +88%).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 8 March, highlights include the following:

- Scale-up of COVID-19 vaccination in priority countries in the African Region with a target to reach 100 million by end of April 2022
- Rapid scale-up of WHO Regional Office for Europe support to address urgent health needs of populations affected by the crisis in Ukraine and refugees in the surrounding countries
- Ramping up COVID-19 vaccination among hard-to-reach communities in Kenya
- Reaching 76% vaccination coverage through a vaccination drive in Mauritius
- Strengthening resilience in vulnerable communities impacted by COVID-19 in India
- Developing key support to address increase in prevalence of anxiety and depression worldwide during the COVID-19 pandemic
- Establishing a global biomanufacturing training hub in the Republic of Korea
- Developing learning resources for leadership in health emergencies accessible via OpenWHO
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

**Newly reported in this update. “●” indicates that information for this variant was received by WHO from official sources. “○” indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information becomes available. **Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.*

See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 3. Methods for Figures 5 and 6

- Figures include ten studies from the Czech Republic, Denmark, Israel, Qatar, South Africa, the United Kingdom, and the United States of America evaluating the VE against the Omicron variant, and 25 studies of the VE against the Delta variant from various countries from the European Region, Region of the Americas, and South-East Asian Region as well as Qatar and Thailand.
- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when either Delta or Omicron was the predominant circulating variant. Estimates were included if they were of laboratory-confirmed cases of the Omicron or Delta variant. In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.
- For the primary series VE, estimates are only included in the plot for studies that report VE for more than one time period.

Annex 4. Summary of primary series vaccine performance against Variants of Concern (VE data as of 3 March 2022; Neutralization data as of 28 February 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺								Vaccines without WHO EUL ⁺	
	AstraZeneca- Vaxzevria/ SII - Covishield	Beijing CNBG- BBIBP-CorV	Bharat-Covaxin	Janssen- Ad26.COV 2.S	Moderna- mRNA-1273	Novavax- Nuvaxovid/ SII - Covavax	Pfizer BioNTech- Comirnaty	Sinovac- CoronaVac	Anhui ZL- Recombinant	Gamma- Sputnik V

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in the study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Annex 4 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than four months after the final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (seven days and over after the final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., >90%).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in Annex 4 represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected more than seven days and less than six months after complete vaccination and that use an ancestral strain as the reference are included in Annex 4.

COVID-19 Weekly Epidemiological Update

Edition 81, published 1 March 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 27 February 2022

Globally, during the week of 21 through 27 February 2022, the number of new COVID-19 cases and deaths has continued to decline by 16% and 10% respectively, as compared to the previous week (Figure 1). Across the six WHO regions, over 10 million new cases and over 60 000 new deaths were reported (Table 1). As of 27 February 2022, over 433 million confirmed cases and over 5.9 million deaths have been reported globally.

At the regional level, while the Western Pacific Region reported an increase (+32%) in the number of new weekly cases, all other regions reported decreases: the Eastern Mediterranean Region (-34%), the Region of the Americas (-30%), the African Region (-25%), the European Region (-24%), and the South-East Asia Region (-16%). The number of new weekly deaths increased in the Western Pacific (+22%) and the Eastern Mediterranean (+4%) Regions, while decreases were reported by the African Region (-59%), South-East Asia Region (-18%), Europe Region (-13%), and the Region of the Americas (-8%).

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 27 February 2022**

**See [Annex 2: Data, table, and figure notes](#)

The highest numbers of new cases were reported from Germany (1 119 632 new cases; -8%), the Republic of Korea (1 032 008 new cases; +69%), the Russian Federation (920 697 new cases; -26%), Turkey (541 259 new cases; -10%), and Brazil (519 785 new cases; -33%).

The highest number of new deaths were reported from the United States of America (13 663 new deaths; 0%), the Russian Federation (5427 new deaths; +3%), Brazil (4361 new deaths; -26%), Mexico (2027 new deaths; +39%), and Turkey (1838 new deaths; -4%)

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 27 February 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	5 592 900 (52%)	-24%	177 622 681 (41%)	22 289 (37%)	-13%	1 867 028 (31%)
Western Pacific	2 661 755 (25%)	32%	23 542 040 (5%)	4 580 (8%)	22%	181 193 (3%)
Americas	1 533 368 (14%)	-30%	146 848 490 (34%)	25 127 (42%)	-8%	2 626 369 (44%)
South-East Asia	639 245 (6%)	-16%	55 680 401 (13%)	4 117 (7%)	-18%	761 642 (13%)
Eastern Mediterranean	309 018 (3%)	-34%	21 124 902 (5%)	3 256 (5%)	4%	333 190 (6%)
Africa	40 296 (0%)	-25%	8 319 957 (2%)	786 (1%)	-59%	169 702 (3%)
Global	10 776 582 (100%)	-16%	433 139 235 (100%)	60 155 (100%)	-10%	5 939 137 (100%)

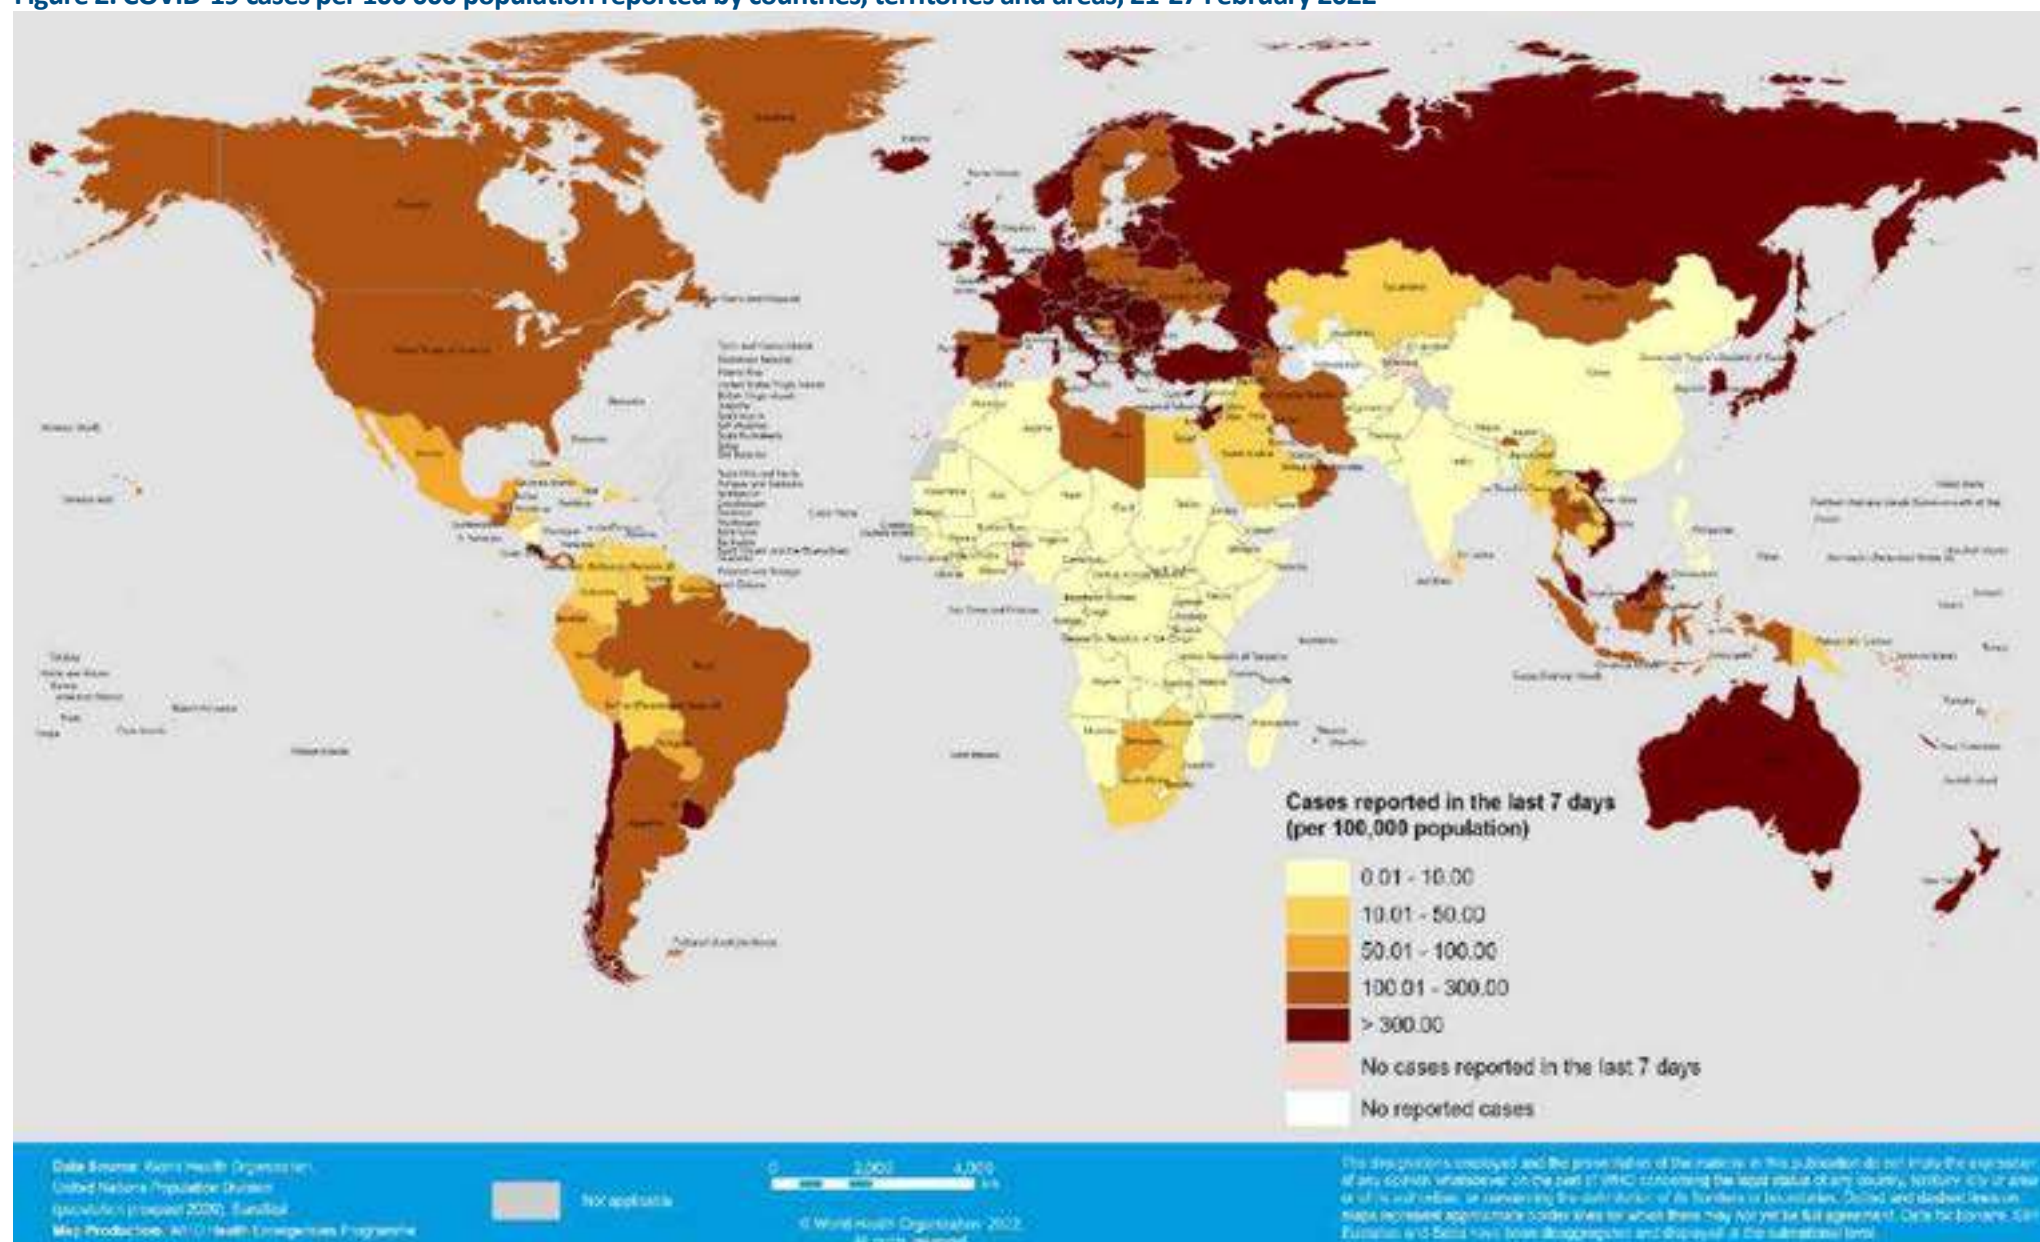

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

**See [Annex 2: Data, table, and figure notes](#)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

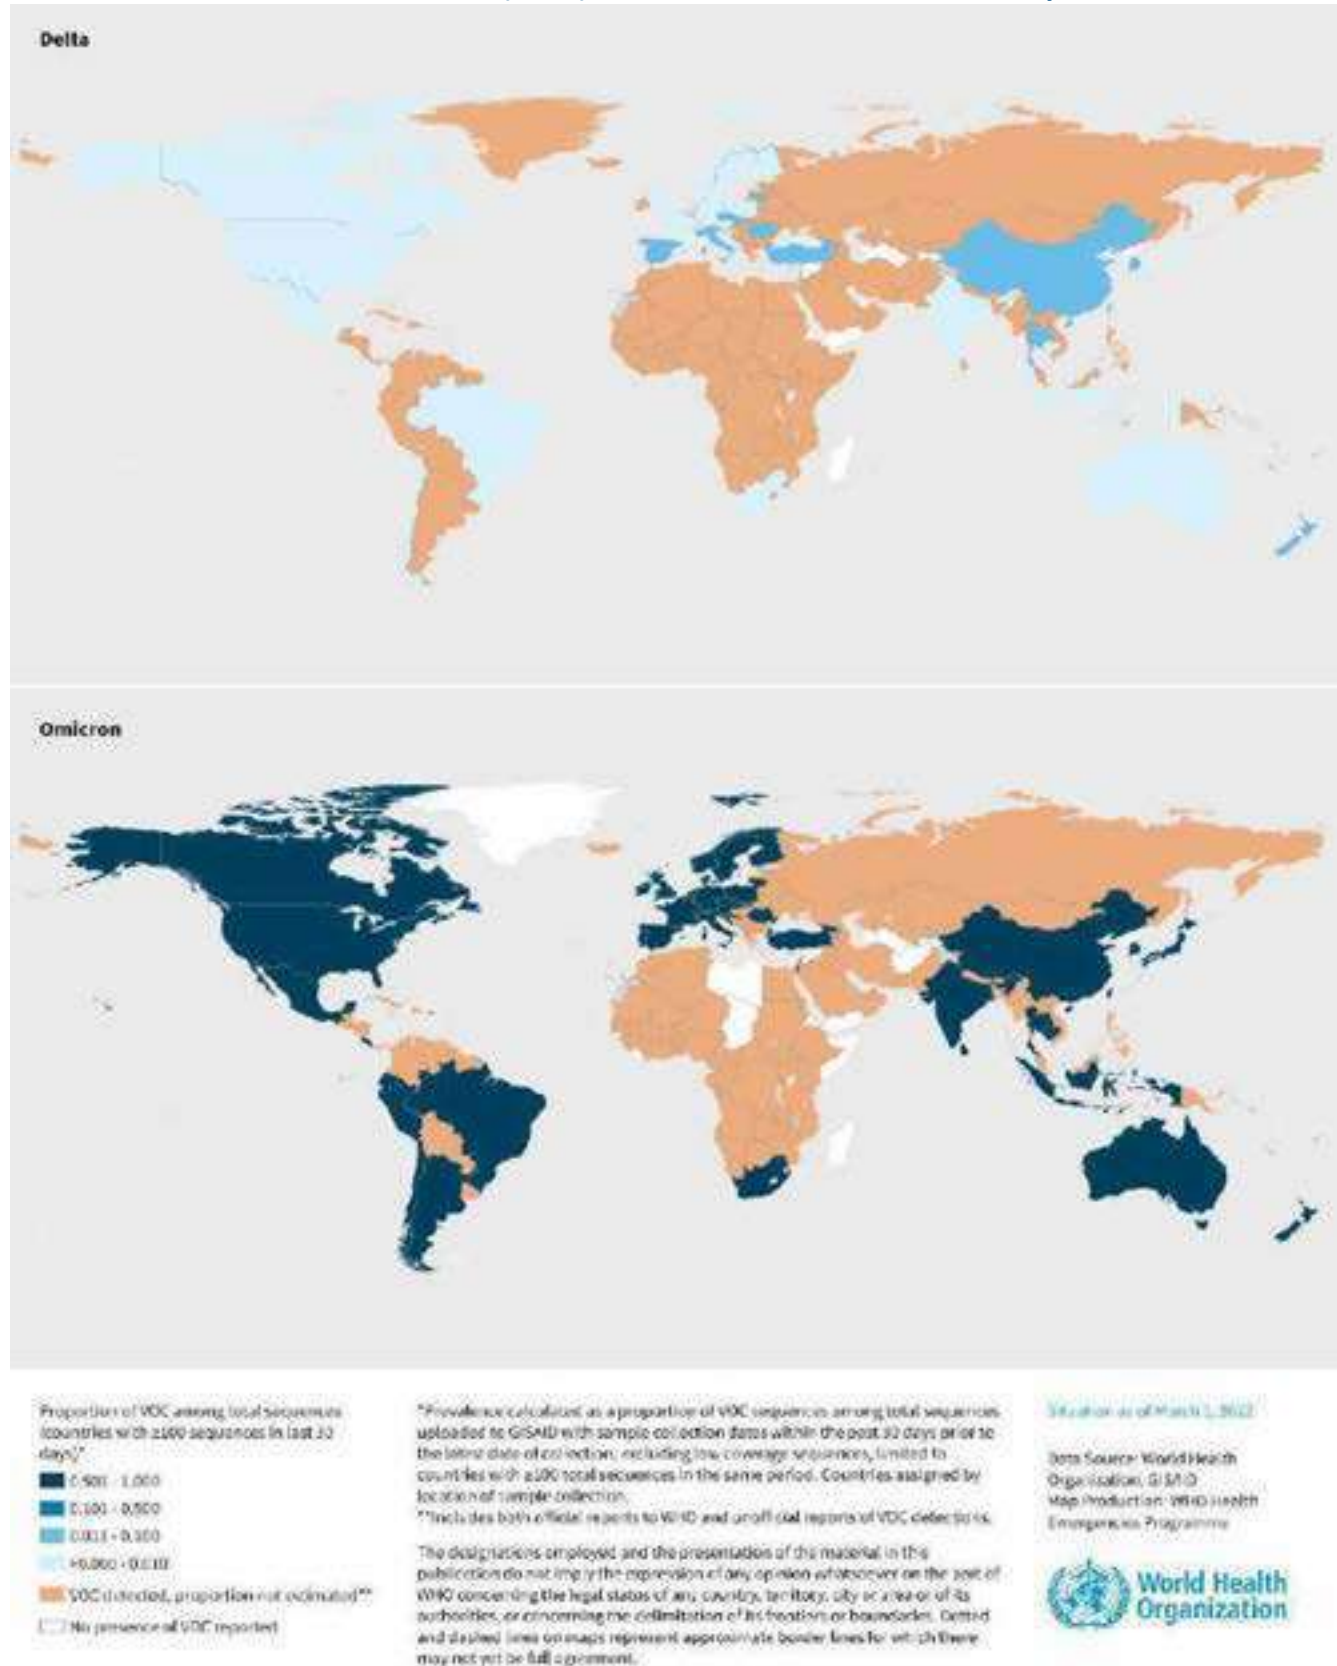

The current global epidemiology of SARS-CoV-2 is characterized by the global dominance of the Omicron variant. Delta remains the only other named variant with significant reported circulation. Among the 488 463 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 486 182 (99.5%) were Omicron, 1 601 (0.3%) were Delta, and six (<0.1%) were Alpha. In the last 30 days, no Beta, Gamma, Lambda, Mu or any other non-VOC/VOI sequences were reported to GISAID. To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

WHO regional overviews

Epidemiological week 21-27 February 2022**

African Region

Since the beginning of January 2022, the African Region has continued to report a decreasing trend in the number of new weekly cases, with over 40 000 new cases reported, a 25% decrease as compared to the previous week. However, eight countries in the Region (16%) reported an increase of over 20% in cases, with the highest proportional increases observed in Lesotho (178 vs 62 new cases; +187%), Congo (73 vs 34 new cases; +115%), and Ghana (904 vs 469 new cases; +93%). The highest numbers of new cases were reported from South Africa (14 900 new cases; 25.1 new cases per 100 000 population; +12%), Réunion (13 632 new cases; 1522.6 new cases per 100 000; -37%), and Zimbabwe (2579 new cases; 17.4 new cases per 100 000; +34%).

The number of new weekly deaths in the Region decreased by 59% as compared to the previous week, with over 700 new deaths reported. The highest numbers of new deaths were reported from South Africa (574 new deaths; 1.0 new deaths per 100 000 population; -65%), Algeria (41 new deaths; <1 new death per 100 000; -43%), and Réunion (37 new deaths; 4.1 new death per 100 000; -3%).

Updates from the [African Region](#)

Region of the Americas

With over 1.5 million new cases reported this week, the Region of the Americas continues to report a decreasing trend (30% decrease as compared to the previous week). However, two countries in the Region have reported increases in new cases of 20% or greater: Honduras (4340 vs 2108 new cases; +106%) and Mexico (76 587 vs 38 921 new cases; +97%). The highest numbers of new cases were reported from Brazil (519 785 new cases; 244.5 new cases per 100 000; -33%), the United States of America (457 058 new cases; 138.1 new cases per 100 000; -36%), and Chile (196 384 new cases; 1027.3 new cases per 100 000; -17%).

The Region reported over 25 000 new deaths this week, an 8% decrease as compared to the previous week. The highest numbers of new deaths were reported from the United States of America (13 663 new deaths; 4.1 new deaths per 100 000; similar to the previous week's figures), Brazil (4361 new deaths; 2.1 new deaths per 100 000; -26%), and Mexico (2027 new deaths; 1.6 new deaths per 100 000; +38%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases have continued to decline following a peak reached in early February 2022. Over 309 000 new cases were reported this week, a 34% decrease as compared to the previous week. The highest numbers of new cases were reported from the Islamic Republic of Iran (105 458 new cases; 125.6 new cases per 100 000; -27%), Jordan (56 356 new cases; 552.3 new cases per 100 000; -49%), and Lebanon (22 279 new cases; 326.4 new cases per 100 000; -28%).

The number of new weekly deaths increased by 4% in the Region when compared to the previous week's figures, with over 3200 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (1592 new deaths; 1.9 new deaths per 100 000; +30%), Tunisia (327 new deaths; 2.8 new deaths per 100 000; +5%), and Egypt (298 new deaths; <1 new death per 100 000; -26%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region has continued to report a decline in new weekly cases following a peak observed at the end of January 2022, with just under 5.6 million new cases reported this week, a 24% decrease as compared to the previous week. The highest numbers of new cases were reported from Germany (1 119 632 new cases; 1346.3 new cases per 100 000; -8%), the Russian Federation (920 697 new cases; 630.9 new cases per 100 000; -26%), and Turkey (541 259 new cases; 641.8 new cases per 100 000; -10%).

The number of new deaths has continued to decrease in the Region, with over 22 000 new fatalities reported this week, a 13% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (5427 new deaths; 3.7 new deaths per 100 000; +3%), Turkey (1838 new deaths; 2.2 new deaths per 100 000; -4%), and Italy (1568 new deaths; 2.6 new deaths per 100 000; -23%).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 639 000 new cases this week, a 16% decline as compared to the previous week, continuing the decreasing trend observed since mid-January 2022. However, Thailand has reported an increase of 32% in new weekly cases (157 301 vs 118 988 new cases) as compared to the previous week. The highest numbers of new cases were reported from Indonesia (341 889 new cases; 125.0 new cases per 100 000; -12%), Thailand (225.4 new cases per 100 000; +32%), and India (93 644 new cases; 6.8 new cases per 100 000; -51%).

Regionally, the number of new deaths declined this week with just over 4100 new deaths reported, an 18% decrease as compared to the previous week. The highest numbers of new deaths were reported from India (1821 new deaths; <1 new death per 100 000; -44%), Indonesia (1708 new deaths; <1 new death per 100 000; +44% increase), and Thailand (267 new deaths; <1 new death per 100 000; +42%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Since the end of December 2021, the Western Pacific Region has continued to report an increase in new weekly cases, with over 2.6 million new cases reported this week, a 32% increase as compared to the previous week. Six countries (22%) in the region reported an increase of 20% or greater in the past week, with the largest increases observed in New Zealand (55 145 vs 10 361 new cases; +432%), China (100 347 vs 26 329; +281%), and Brunei Darussalam (22 972 vs 10 934 new cases; +110%). The highest numbers of new cases were reported from the Republic of Korea (1 032 008 new cases; 2012.9 new cases per 100 000; +69%), Viet Nam (478 884 new cases; 492.0 new cases per 100 000; +87%), and Japan (473 461 new cases; 374.3 new cases per 100 000; -18%).

The number of new weekly deaths continue to increase, with over 4500 new deaths reported, a 22% increase as compared to the previous week. The highest numbers of new deaths were reported from Japan (1634 new deaths; 1.3 new deaths per 100 000; +14%), the Philippines (744 new deaths; <1 new death per 100 000; +10%), and Viet Nam (627 new deaths; <1 new death per 100 000; +12%).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition, highlights include the following:

- Scaling-up IPC capacity in Cox's Bazar in response to COVID-19 pandemic furthers streamlining of best practices in general health facilities
- Conducting health worker training on Acute Respiratory Distress Syndrome Clinical Management in Nepal
- Supporting mass gathering risk-based approaches to hosting Africa Cup of Nations (AFCON) in Cameroon
- Integrating COVID-19 and influenza sentinel surveillance in Mongolia
- Supporting Infection Prevention and Control as part of Yemen's COVID-19 response with technical mission
- Training of national mentors and laboratory experts on verification and validation of examination procedures in Kyrgyzstan
- Hosting vaccine pop-ups in the Bahamas with PAHO support
- Supporting students in Cambodia with psychological first aid framework and operationalization during the COVID-19 pandemic
- Host new Myanmar learning channel for COVID-19 vaccination training in local languages
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

**Newly reported in this update. “●” indicates that information for this variant was received by WHO from official sources. “○” indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information becomes available. **Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.*

See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 80, published 22 February 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 20 February 2022

Globally, during the week of 14 through 20 February 2022, the number of new COVID-19 cases decreased by 21% as compared to the previous week. In addition, the number of new deaths showed a decreasing trend (-8%) when compared to the previous week (Figure 1). Across the six WHO regions, over 12 million new cases and over 67 000 new deaths were reported (Table 1). As of 20 February 2022, over 422 million confirmed cases and over 5.8 million deaths have been reported globally.

At the regional level, the Western Pacific Region reported a 29% increase in the number of new weekly cases, while all other regions reported decreases: the Eastern Mediterranean Region (-34%), the Region of the Americas (-29%), the European Region (-26%), the African Region (-22%) and the South-East Asia Region (-17%). The number of new weekly deaths increased in the Western Pacific (+21%) and African (+20%) Regions and decreased in the South-East Asia (-37%), the Regions of Americas (-9%), the European Region (-5%) and the Eastern Mediterranean Region (-4%).

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 20 February 2022**

**See [Annex 2: Data, table, and figure notes](#)

The highest numbers of new cases were reported from the Russian Federation (1 236 910 new cases; -7%), Germany (1 218 465 new cases; -8%), Brazil (773 353 new cases; -23%), the United States of America (746 129 new cases; -39%), and the Republic of Korea (612 195 new cases; +80%).

The highest number of new deaths were reported from the United States of America (14 723 new deaths; -6%), Brazil (5877 new deaths; -11%), the Russian Federation (5252 new deaths; +8%), India (3238 new deaths; -51%), and Mexico (2221 new deaths; +8%).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 20 February 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the global dominance of the Omicron variant. Delta remains the only other named variant with significant reported circulation. Among the 495 016 sequences uploaded to [GISAID](#) with specimens collected in the last 30 daysⁱ 490 519 (99.1%) were Omicron, 3 841 (0.8%) were Delta, one (<0.1%) was Alpha and one non VOI/VOC sequence. In the last 30 days, no Beta, Gamma, Lambda or Mu sequences were reported to GISAID. To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

The Omicron variant

Differences in the characteristics of VOCs

Available evidence on the phenotypic impacts of VOCs is reported in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last update on 8 February 2022](#), there have been several new publications on the phenotypic characteristics of VOCs, including Omicron. Some of these studies have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Update on the Omicron VOC

This section provides a summary of the potential impact of the Omicron variant. Detailed information on this variant and related recommended priority actions for Member States can be found in the updated [Technical Brief and Priority Actions for Member States](#) as well as under the [Country and Technical Guidance – Coronavirus Disease \(COVID-19\)](#). Based on the currently available evidence (Table 2), the overall global risk related to the Omicron variant remains very high.

Since the first reporting of the Omicron variant in November 2021, almost 1.5 million sequences have been deposited in GISAID. By the first week of January 2022, Omicron accounted for 90% of submitted sequences; by week five, Omicron had largely replaced all other variants and now accounts for over 99% of submitted sequences. Amongst the major Omicron lineages, BA.1 predominates overall, followed by BA.1.1 and BA.2, with BA.3 being the

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 19 January to 17 February 2022 (last reported sample at the time of data extraction), excluding low coverage sequences. Proportions are estimated for countries submitting more than 100 total sequences. In the past 30 days, 30 countries submitted a total of 100 sequences and above on GISAID.

least frequently detected. Weekly trends (figure 4, panel A) show that the relative proportion of BA.2 has increased over time, becoming the second most frequently detected lineage after BA.1.1 by week 6, and the dominant lineage in 18 countries. This trend is most pronounced in the South-East Asia region, followed by the Eastern Mediterranean, African, Western Pacific and European Regions. In contrast, very little BA.2 has been detected in the Americas, and no growth has been observed for the BA.3 lineage. Increased sequence variation has been observed within the BA.1 and BA.2 lineages over time, in line with increasing transmission. The weekly number of Omicron sequences has been steadily decreasing since the beginning of 2022 (figure 4, panel B). This trend should be interpreted with some caution, as data for the most recent weeks may be incomplete due to the delay between specimen collection and submission of sequences to GISAID (median delay from week 1 of 2022: 13 days). In addition, some countries may have changed their testing and sequencing policies during the presented period.

Figure 4. Global distribution and relative proportion of Omicron lineages for sequences submitted to GISAID presented by week of specimen collection

Global distribution of Omicron lineages from sequences and metadata submitted to GISAID.

Panel A: Relative proportions of Omicron lineages over the last 4 weeks by specimen collection week.

Panel B: Incidence of Omicron lineages by week of specimen collection.

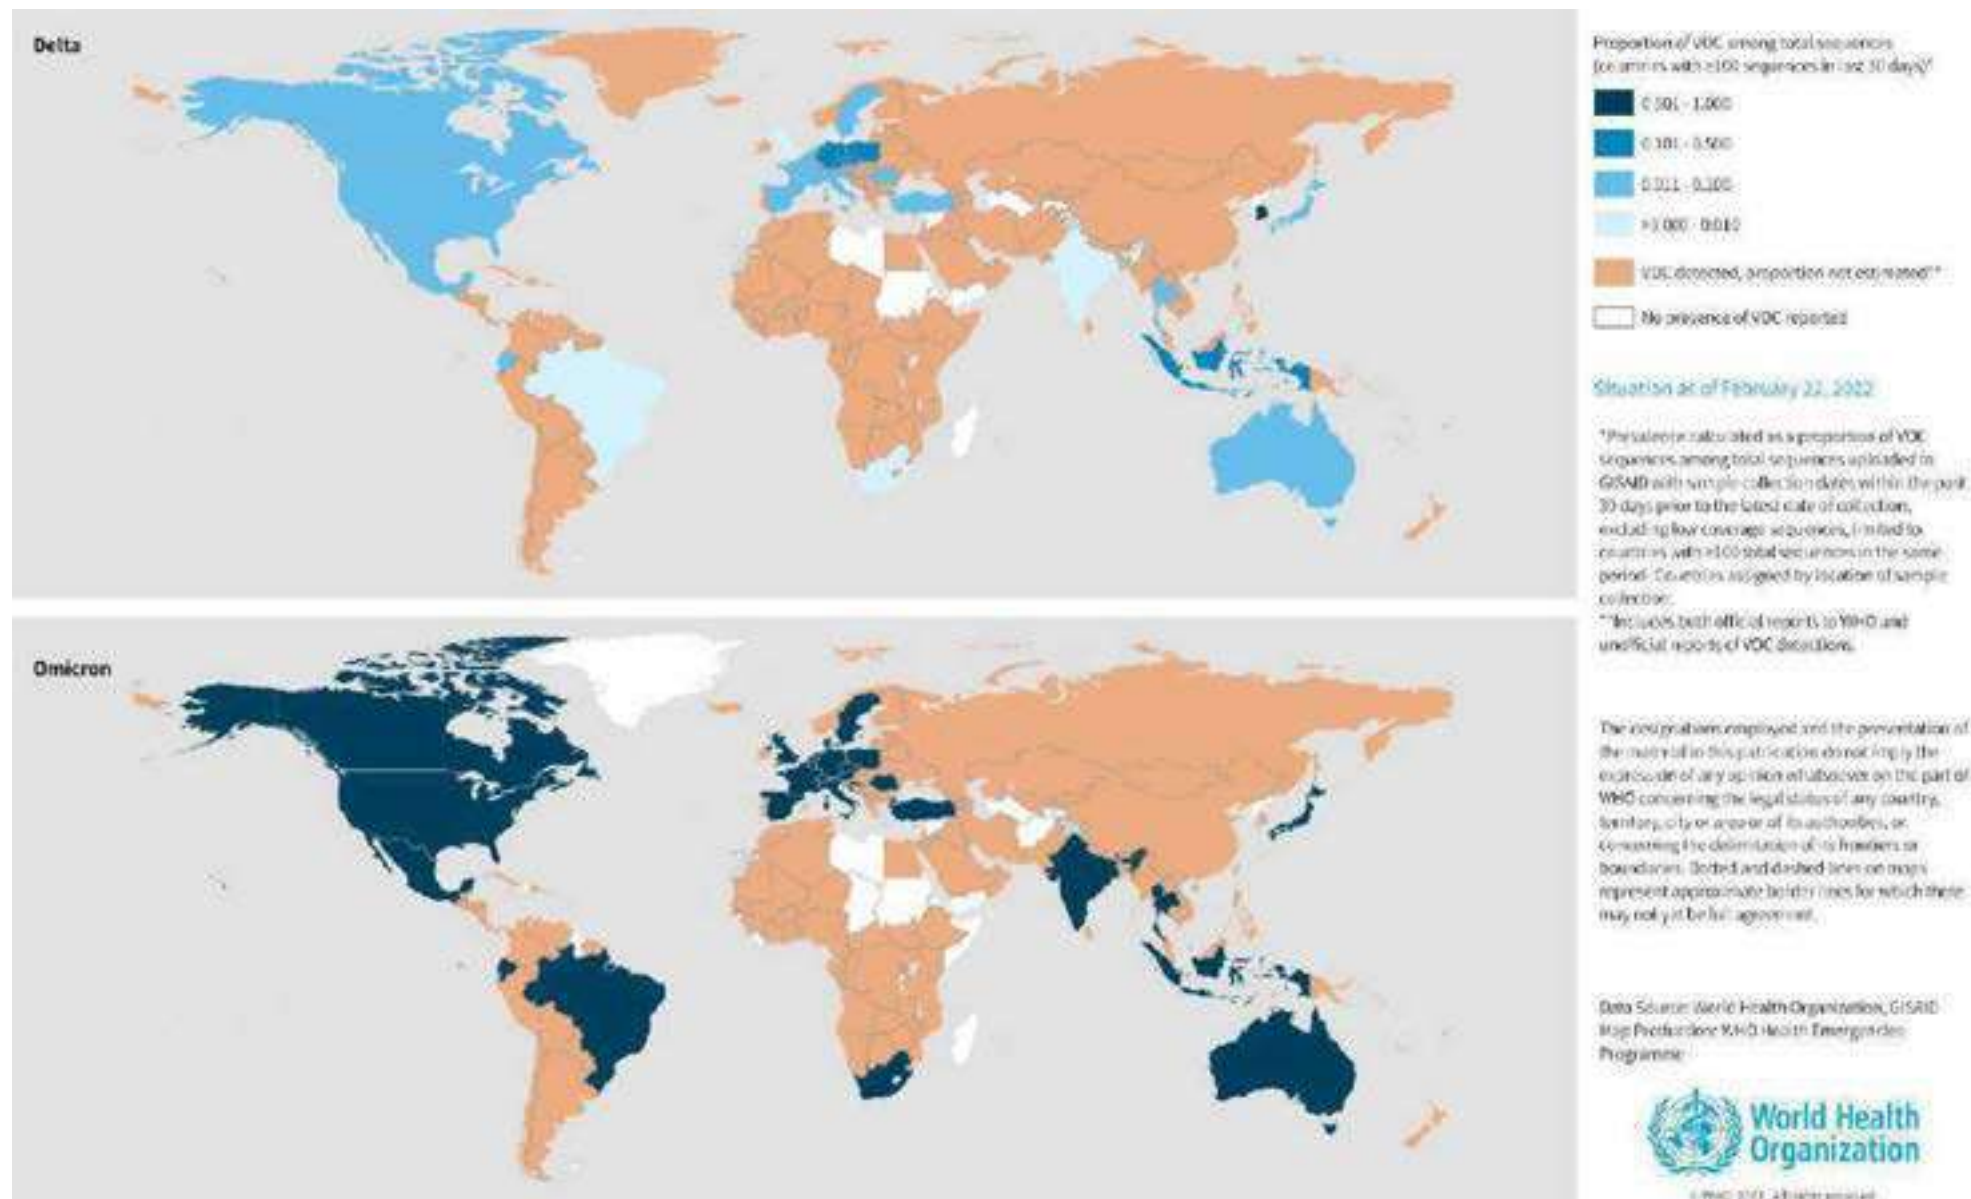

Data was extracted from GISAID on 21 February 2022 at 14:00 CET; figures are correct at the time of printing.

Table 2: Summary of current evidence on the Omicron variant of concern

Domain	Indicator	Main results
Epidemiology	Impact on disease incidence	<ul style="list-style-type: none"> - Omicron continues to spread globally and has been identified in most countries in all six WHO regions. - Globally, during the week of 14 through 20 February 2022, the number of new COVID-19 cases decreased by 21% as compared to the previous week. The number of new deaths also showed a decreasing trend (8%). At the regional level, the Western Pacific Region reported a 29% increase in the number of new weekly cases while all other regions reported decreases. - It is important to note that these trends may be due, in part, to an overall decrease in testing as some countries may have changed their testing and sequencing policies during the presented period.
	Impact on transmission	<ul style="list-style-type: none"> - An analysis based on the methods used by Campbell et al¹, and that focused on countries with sufficient sequence data uploaded to GISAID as of 18 February, found a growth rate advantage of Omicron over Delta in all countries. - This translated to a pooled mean transmission advantage (i.e., relative difference in effective reproduction numbers) of 77% (95% CI: 66% – 95%) across epidemiological contexts, under the assumption of an unchanged generation time (i.e. the duration between the moment a person gets infected to the moment they infect another person). The generation time of Omicron has been found to be shorter as compared to Delta, which suggests the transmission advantage may be lower than estimated above; for a 20% shorter generation time, the estimated pooled mean transmission advantage of Omicron over Delta is 66% (95% CI: 60% – 82%). - The same analysis demonstrates a growth rate advantage of the Omicron Pango lineage BA.2 over the Pango lineage BA.1, with a pooled mean transmission advantage of 63% (95% CI: 47% – 77%), under the assumption of an unchanged generation time. - Higher secondary attack rates were reported for Omicron compared to Delta: 13.6% (95% CI: 13.1%-14.1%) vs 10.1% (95% CI: 10.0%-10.2%) in the United Kingdom,² and 31% vs. 21% in Denmark.³ - Researchers in China, Hong Kong SAR⁴ found that Omicron had a higher tropism for the bronchi tissue compared to lungs. In the United Kingdom,⁵ Omicron was found to infect the upper respiratory tract more rapidly than Delta, yielding about 100-fold higher titres. - Two studies conducted in South Africa^{6,7} reported evasion from vaccine-induced and infection-induced immunity by Omicron. This could also be a contributing factor to the higher growth rates of Omicron compared to Delta.
	Impact on disease severity	Following analyses of patterns in recent medical consultations and hospitalizations, Omicron was consistently found to be associated with less severe disease compared to Delta across studies conducted in the United Kingdom, ⁸ the United States of America, ^{9,10} Canada ¹¹ and South Africa. ¹²
Immune response	Impact on reinfection	Preliminary data on Omicron in individuals previously infected with SARS-CoV-2 since the start of the pandemic showed an increase in the number of reinfections in Denmark ¹³ and Israel. ¹⁴ A higher risk (RR = 3.3; 95%CI: 2.8 – 3.8) of reinfection with Omicron compared to other SARS-CoV-2 variants was reported across the United Kingdom, with an even higher risk (RR = 5.4; 95%CI: 4.9 – 6.0) when reported only from England. ¹⁵
	Impact on vaccination	Results of vaccine effectiveness (VE) studies are difficult to interpret, and estimates vary with the type of vaccine administered and the number of doses and scheduling (sequential administration of different vaccines). Studies conducted in the United Kingdom and the United States of America reported 60% – 75% vaccine effectiveness against symptomatic infection with Omicron. ¹⁶ See more details in the section below .
	Impact on antibody responses and cellular immunity	An analysis of neutralization data from 23 laboratories found a 20-fold reduction in neutralization associated with the Omicron variant in unvaccinated, previously infected individuals or individuals who had received two vaccine doses, while sera from vaccinated individuals with previous infection or individuals who had received three vaccine doses showed a seven-fold reduction. ¹⁷ This reduced

Domain	Indicator	Main results
		humoral response could be associated with an increased risk of reinfection. Conversely, studies on cellular immunity showed well preserved responses (70% – 80% of CD4+ and CD8+ responses) that could be associated with a decreased risk of severe disease. ^{18–22}
Diagnostic tools	Impact on PCR assays	Apart from the BA.2 lineage, all Omicron descendent variants have the 69-70 deletion responsible for S-gene target failure. Evaluation of PCR tests for SARS-CoV-2 that include multiple gene targets revealed limited impact of the Omicron variant on the diagnostic test accuracy of these assays. ^{23,24}
	Impact on Rapid Diagnostic tests	Preliminary data showed contradictory results, with some indicating that Ag-RDTs have similar sensitivity to Omicron as to the wild-type virus or other VOCs, while other studies found a difference. This variability in test performance was also found in more recent studies. ^{25,26}
Impact on treatment	Impact on antivirals	Preliminary data from several research projects showed no difference in the effectiveness of antiviral agents against Omicron. ^{27–29}
	Impact on biologicals	Studies on the effectiveness of monoclonal antibodies for treating patients with Omicron reported conserved neutralizing activity for three broadly neutralizing monoclonal antibodies (sotrovimab, S2X259 and S2H97) and a reduction in effectiveness of other monoclonal antibodies (Planas 2021, VanBlargan 2021, Cameroni 2021, Wilhelm 2021, Roche 2021). ^{30–34}
	Other treatment options	It is anticipated that other therapeutics for the clinical management of severe and critical COVID-19 patients (e.g. Interleukin-6 receptor blockers and corticosteroids, will maintain their effectiveness.

Figure 5: Prevalence of variants of concern (VOCs) Delta and Omicron in the last 30 days, data as of 22 February 2022

See also [Annex 2](#) for reported VOC detections by country/territory/area

Figure 6. Vaccine effectiveness (VE) of primary series and booster vaccination against the Delta variant of concern

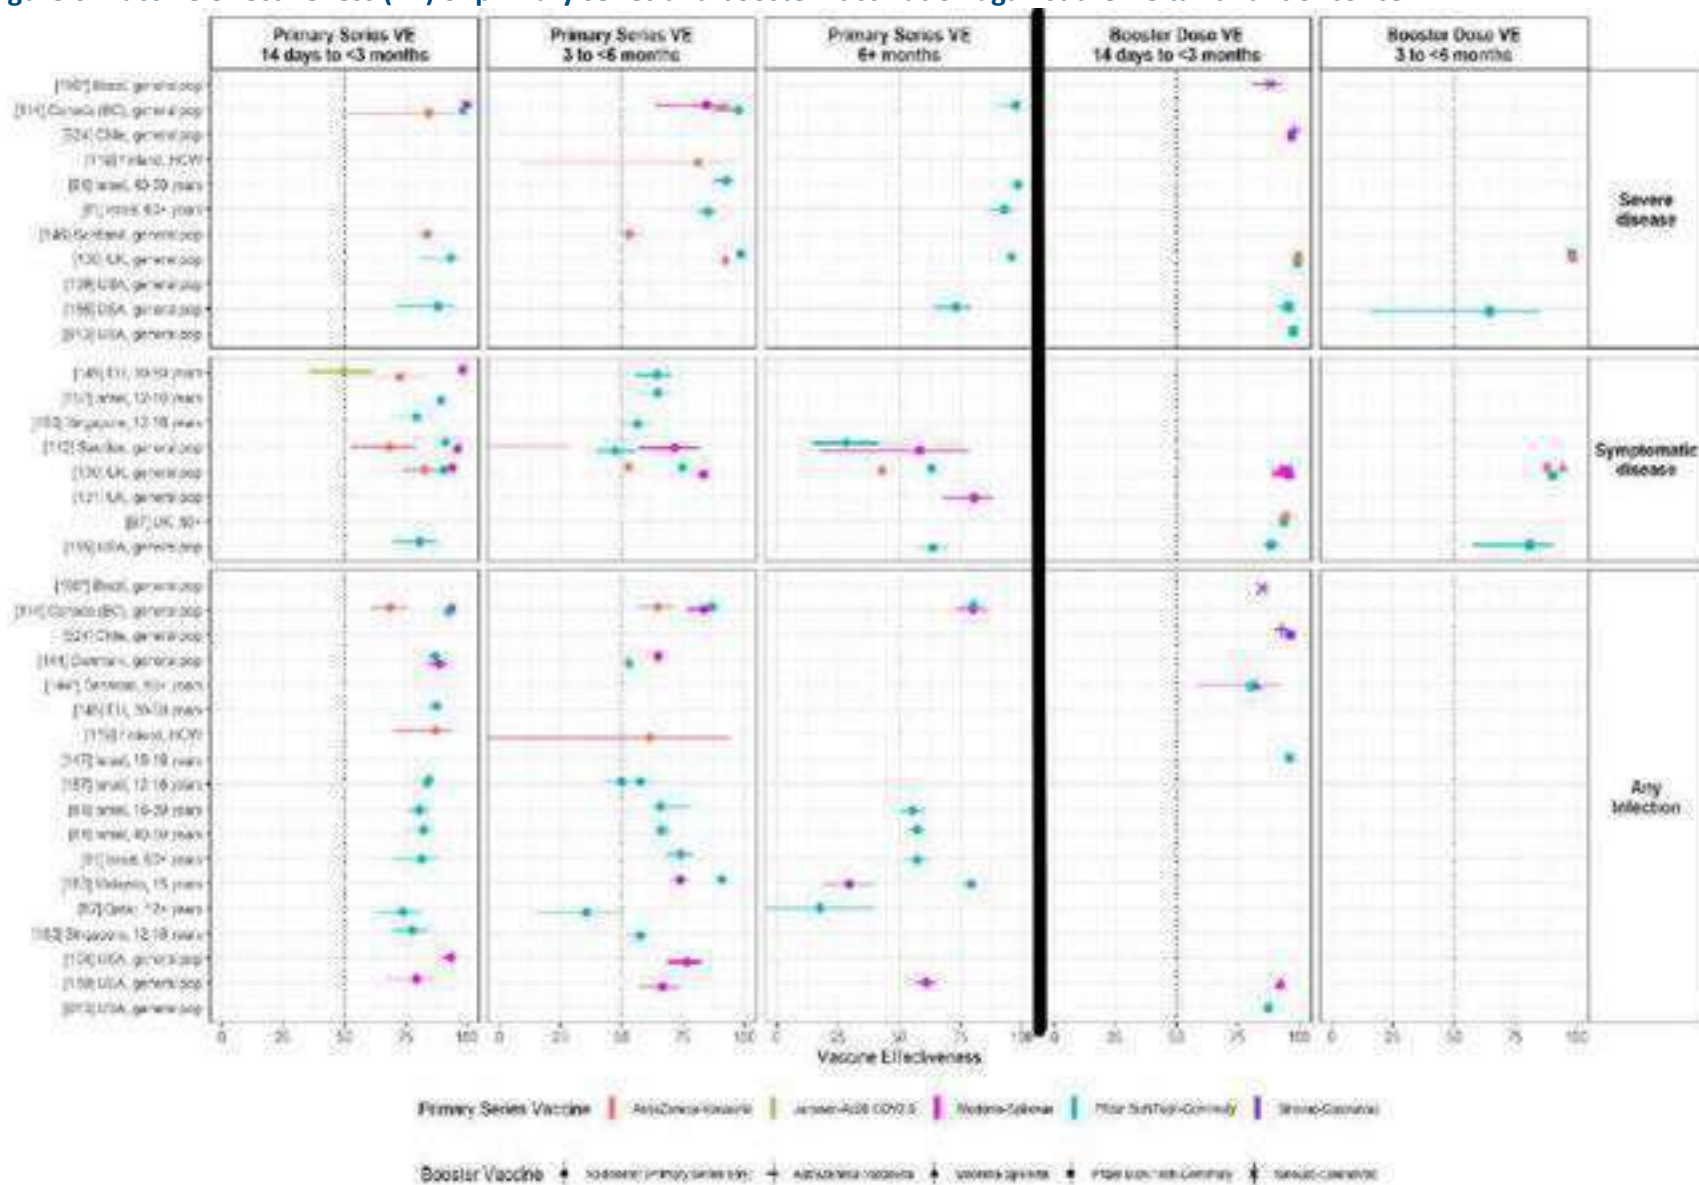

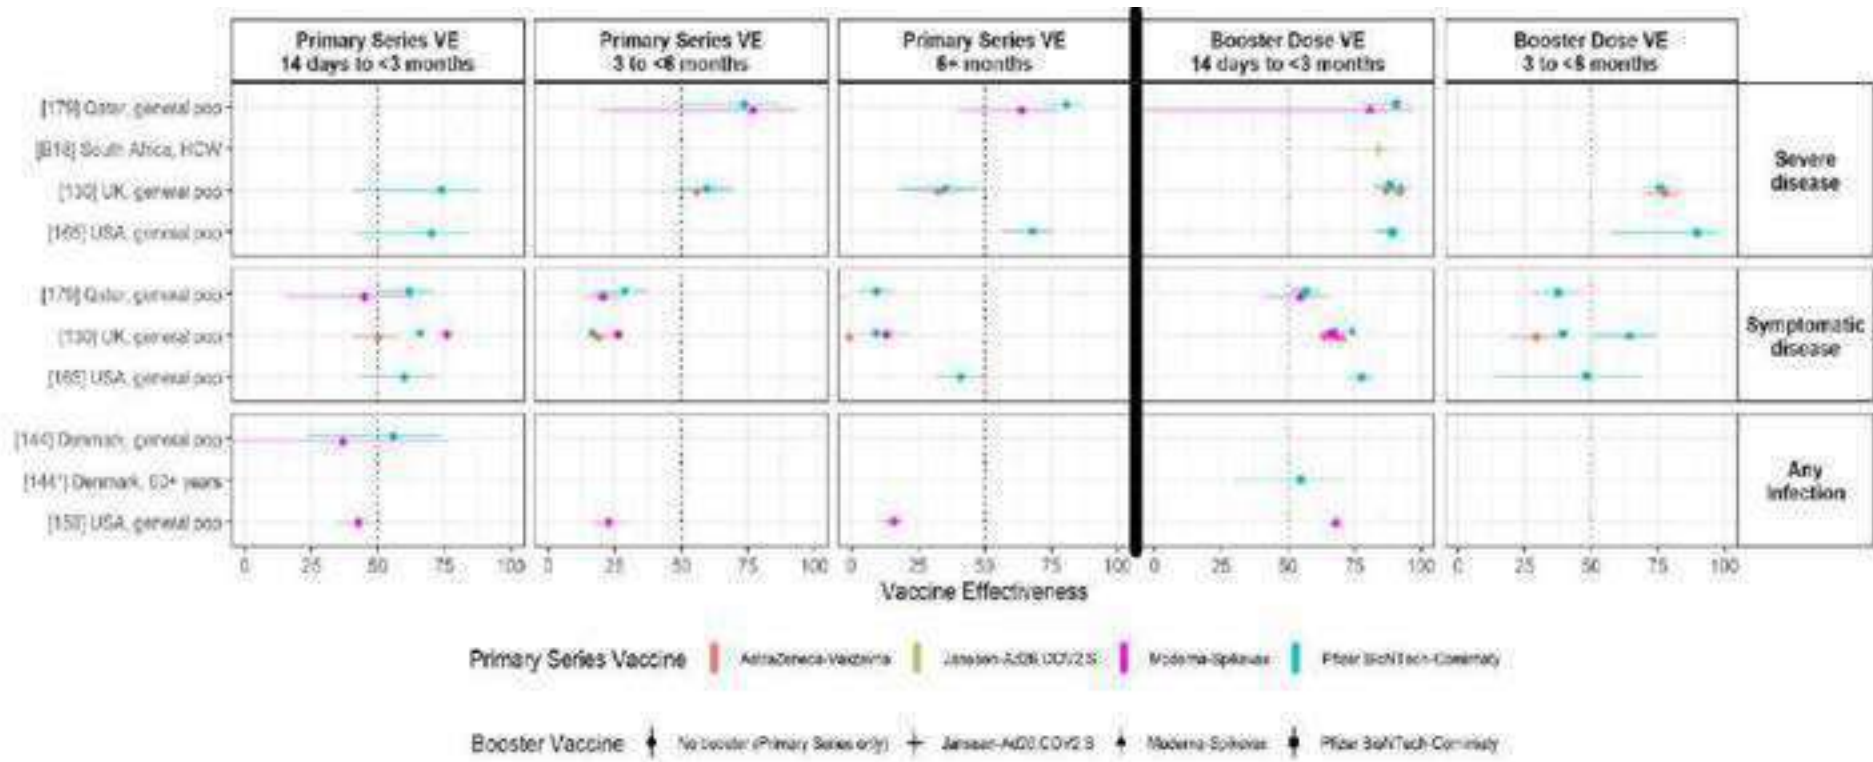

Figure 7. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

*Indicates booster dose vaccine effectiveness evaluated using persons completing primary series as reference group, rather than unvaccinated persons. Abbreviations: pop=population; HCW=healthcare workers; EU=European Union. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the [summary table](#) of VE effectiveness studies on [view-hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for Astra-Zeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2. Severe disease includes hospitalization; symptomatic disease includes disease of any severity level; any infection can include symptomatic and asymptomatic infection. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, three negative point estimates for the primary series are not shown in the Omicron plot: Moderna-Spikevax VE against symptomatic disease at 6+ months (reference 179) as well as Moderna-Spikevax and Pfizer BioNTech-Comirnaty VE against infection at 3-6 months (reference 144); one negative point estimate for primary series is not shown in the Delta plot: AstraZeneca-Vaxzevria VE against Delta symptomatic disease (reference 112) with 95% Cis crossing 0 is not fully visible in the plot.

Figures 6 and 7 summarize the impact of Delta and Omicron variants, respectively, on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. Since the [last update](#), one new study (pre-print) from Qatar³⁵ has evaluated primary series and booster dose VE of Pfizer BioNTech-Comirnaty and Moderna-Spikevax vaccines against symptomatic and severe disease due to Omicron; and one new peer-reviewed study from Brazil³⁶ has assessed VE of three doses of Sinovac-CoronaVac against infection and severe disease in the context of Delta. The methods for including estimates in the plot are described below. Additional information on vaccine performance against VOCs can also be found in Annex 4.

Interpretation of the results of VE for the Delta variant

Most of the evidence to date indicates that effectiveness of the mRNA vaccines (Pfizer BioNTech-Comirnaty and Moderna-Spikevax) remains high against *severe disease* associated with Delta variant infection at six or more months after the primary series, with three of four studies reporting VE estimates of >90% and one study reporting a VE of 74% at six months or more. Three studies report high VE (>80%) of the AstraZeneca-Vaxzevria vaccine three to six months following the primary series, while one study reports a lower VE (54%), compared to the first three months (84%).

VE estimates against *symptomatic disease* and *infection* range from 73 to 96% following the primary series of one of the two mRNA vaccine from 14 days up to three months after vaccination and 68-88% following the primary series of the AstraZeneca-Vaxzevria vaccine during the same time period. There is, however, consistent evidence of decreasing VE against *symptomatic disease* and *infection* over time following the primary series for all of the vaccines for which data are available. Despite this, most of the evidence still shows VE estimates of >50% (59-80%) at six months or more following mRNA vaccine, with four estimates falling below 50%. Three of the four studies evaluating the AstraZeneca-Vaxzevria vaccine also showed a VE >50% (54-65%) at three to six months, though in one of these studies the VE decreased to 43% at six or more months following the primary series. A single study of Sinovac-CoronaVac (an inactivated vaccine) conducted in Malaysia reported a VE against *infection* of 74% three to six months following the primary series, which decreased to 30% beyond six months.

Receipt of a booster dose of mRNA, vector-based and inactivated vaccines for which there are data available resulted in a VE of $\geq 79\%$ for *all outcomes* within the first three months. At three to six months following the booster dose, the VE of a Pfizer BioNTech-Comirnaty booster following Pfizer BioNTech-Comirnaty or AstraZeneca-Vaxzevria primary series remained >95% against *severe disease* in a single study conducted in the United Kingdom, but decreased from 95% to 65% with Pfizer BioNTech-Comirnaty primary series and booster in a single study conducted in the United States of America. In the same two studies, the VE against *symptomatic disease* at three months or more following a booster dose with an mRNA vaccine was >75% after a primary series of either the AstraZeneca-Vaxzevria or the Pfizer BioNTech-Comirnaty vaccines.

Interpretation of the results of VE for the Omicron variant

Six studies of VE for the Omicron variant show lower protection of the primary series COVID-19 vaccines for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed previously for other VOCs. Importantly, VE estimates against the Omicron variant remains highest for *severe disease*, while they are lower for *symptomatic disease* and *infection*. Booster vaccination substantially improves VE for all outcomes for all products for which there are data. More data are needed to characterize the duration of the VE following a booster dose.

VE estimates for the Pfizer BioNTech-Comirnaty vaccine against *severe disease* due to the Omicron variant within the first three months following the primary series (without a booster dose) range from 70 to 74% and decrease over time since vaccination, with VE estimates of 60-74% between three and six months, and 35-80% at six months or more. In three to six months versus six months or longer, VE estimates for the AstraZeneca-Vaxzevria vaccine against *severe disease* reduced from 56% to 33%, with relatively wide confidence intervals (see Figure 7 for details).

Early VE estimates (measured from 14 days up to three months after vaccination) of the primary series against *symptomatic disease* are generally lower than those for *severe disease*, though they remain at or above 50% for AstraZeneca-Vaxzevria, Moderna-Spikevax, and Pfizer BioNTech-Comirnaty vaccines, except for one study that reported VE of 45% (95% CI: 16-64%) for Moderna-Spikevax. VE against *infection* at 14 days up to three months after the primary series was lower, ranging from 37 to 55%. All available estimates against both *symptomatic disease* and *infection* measured three or more months after completion of the primary series indicate VE estimates of less than 50% for the three vaccines.

A booster dose increases VE estimates against *severe disease* to above 75% for all vaccines for which data are available, with this effect maintained up to six months after the booster dose. A booster dose increased VE estimates against *symptomatic disease* in the first three months following vaccination substantially, by at least 37 percentage points across all studied vaccines, with VE ranging from 55% to 78%. However, VE decreased to 29-64% at three to six months. Limited evidence is available for VE against *infection* due to the Omicron variant following a booster dose, with only one study showing a VE of 68% within the first three months of a booster dose of Moderna-Spikevax.

WHO regional overviews Epidemiological week 14-20 February 2022**

African Region

The African Region has reported a continued decrease in the number of cases since the beginning of January 2022, with over 53 000 new cases reported, a 22% decrease as compared to the previous week. However, four countries in the Region (8%) reported an increase of over 20% in cases: Ghana (469 vs 210 new cases; +123%), Equatorial Guinea (17 vs 8 new cases; +112%), Zimbabwe (1925 vs 964 new cases; +99%) and Burkina Faso (40 vs 26 new cases; +53%). The highest numbers of new cases were reported from Réunion (21 707 new cases; 2424.5 new cases per 100 000 population; -29%), South Africa (16 929 new cases; 28.5 new cases per 100 000; -6%), and Algeria (2710 new cases; 6.2 new cases per 100 000; -25%).

With just over 1900 new deaths reported this week, the Region shows a 20% increase when compared to the previous week. This increase is driven by a backlog of deaths reported by South Africa following an ongoing audit exercise. The highest numbers of new deaths were reported from South Africa (1632 new deaths; 2.8 new deaths per 100 000 population; +40%), Algeria (72 new deaths; <1 new death per 100 000; similar to previous week), and Réunion (38 new deaths; 4.2 new deaths per 100 000; +12%).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 2.2 million new cases, a 29% decrease as compared to the previous week, a trend that has continued since mid-January. However, three countries have reported increases in new cases of 20% or greater, with the highest proportional increases reported from Mexico (90 422 vs 53 344 new cases; +70%), Nicaragua (85 vs 65 new cases; +31%) and, Saint Lucia (536 vs 419; +28%). The highest numbers of new cases were reported from Brazil (773 353 new cases; 363.8 new cases per 100 000; -23%), the United States of America (746 129 new cases; 225.4 new cases per 100 000; -39%), and Chile (236 312 new cases; 1236.2 new cases per 100 000; -5%).

The Region reported just under 29 000 new deaths this week, a 9% increase as compared to the previous week. The highest numbers of new deaths were reported from the United States of America (14 723 new deaths; 4.4 new deaths per 100 000; -6%), Brazil (5877 new deaths; 2.8 new deaths per 100 000; -12%), and Mexico (2221 new deaths; 1.7 new deaths per 100 000; +8%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, new weekly cases continue to decline for the second consecutive week since the peak reached in early February 2022. Over 466 000 new cases were reported this week, representing a 34% decrease as compared to the previous week. The highest numbers of new cases were reported from the Islamic Republic of Iran (145 032 new cases; 172.7 new cases per 100 000; -39%), Jordan (110 012 new cases; 1078.2 new cases per 100 000; -19%), and Lebanon (30 984 new cases; 453.9 new cases per 100 000; -33%).

The number of new weekly deaths remains stable when compared to the previous week's figures, with over 3100 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (1228 new deaths; 1.5 new deaths per 100 000; +49%), Egypt (402 new deaths; <1 new death per 100 000; -3%), and Tunisia (310 new deaths; 2.6 new deaths per 100 000; -32%).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported a further decline this week with over 7.2 million new cases, a 26% decrease as compared to the previous week. This is the third consecutive week of a decline in the number of new cases since the Region observed a peak at the end of January. Only one country – Iceland – reported a greater than 20% increase this week (17 293 vs 13 333 new cases; +30%). The highest numbers of new cases were reported from the Russian Federation (1 236 910 new cases; 847.6 new cases per 100 000; -7%), Germany (1 218 465 new cases; 1465.1 new cases per 100 000; -8%), and Turkey (599 596 new cases; 710.9 new cases per 100 000; -12%).

This week, over 24 000 new deaths were reported in the Region, a 5% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Russian Federation (5252 new deaths; 3.6 new deaths per 100 000; +9%), Italy (2024 new deaths; 3.4 new deaths per 100 000; -11%), and Turkey (1922 new deaths; 2.3 new deaths per 100 000; +11%).

Updates from the [European Region](#)

South-East Asia Region

A decline in new cases has been observed in the South-East Asia Region since mid-January. Over 762 000 new cases were reported in the Region this week, a 17% decrease as compared to the previous week. Despite the declining trend at the regional level, four countries reported an increase of over a 20% e: Myanmar (18 896 vs 8870 new cases; +113%), Bhutan (2649 vs 1337 new cases; +98%), Indonesia (389 727 vs 291 298 new cases; +34%) and Thailand (118 988 vs 96 326 new cases; +24%). The highest numbers of new cases were reported from Indonesia (142.5 new cases per 100 000), India (191 052 new cases; 13.8 new cases per 100 000; -57%), and Thailand (170.5 new cases per 100 000).

Regionally, the number of new deaths also declined this week with just over 5000 new deaths reported, a 37% decrease as compared to the previous week. The highest numbers of new deaths were reported from India (3238 new deaths; <1 new death per 100 000; -52%), Indonesia (1189 new deaths; <1 new death per 100 000; +91%), and Thailand (188 new deaths; <1 new death per 100 000; +30%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported a sharp increase (29%) in new weekly cases as compared to the previous week, with over two million new cases. More than a third (11/28; 39%) of the countries in the Region reported an increase of 20% or greater in the past week. The most substantial increases were observed in New Zealand (10 361 vs 2792 new cases; +271%), China (26 329 vs 7571 new cases; +248%) and Brunei Darussalam (10 934 vs 4175 new cases; +162%). The highest numbers of new cases were reported from the Republic of Korea (612 195 new cases; 1194.1 new cases per 100 000; +80%), Japan (579 928 new cases; 458.5 new cases per 100 000; -7%), and Viet Nam (255 812 new cases; 262.8 new cases per 100 000; +63%).

Over 3700 new deaths were reported in the Region this week, a 21% increase as compared to the previous week. The highest numbers of new deaths were reported from Japan (1434 new deaths; 1.1 new deaths per 100 000; +52%), the Philippines (677 new deaths; <1 new death per 100 000; -5%), and Viet Nam (561 new deaths; <1 new death per 100 000; -7%).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 22 February, highlights include the following:

- Supporting the acceleration of COVID-19 vaccination rollout in Georgia through technical support
- Scaling up genomic sequencing in Nigeria to support policymakers
- WHO and partners working together to support Pacific Island Countries as COVID-19 gains a foothold in the Region
- WHO supports the scaling-up suicide prevention during COVID-19 in Bhutan
- With support of WHO's core contributors, health services and on-site vaccine opportunities were implemented in Iraq
- GOARN expert deployed by WHO to support the Commonwealth of Northern Mariana Islands' COVID-19 response
- Overview of OpenWHO superusers and the most popular COVID-19 online courses
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

*indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information becomes available. **Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.*

See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 3. Methods for the update on BA.2 Pango lineage of the Omicron variant of concern

We conducted a search for published and unpublished studies on the BA.2 Pango lineage of the Omicron variant. The search for published studies was conducted in Medline while the search for unpublished literature was conducted in MedRxiv, which is a repository for preprints. We searched for studies and reports with an abstract in English, that were accessible up to 14 February 2022. Search terms used were “BA.2” and “Omicron Pango lineages”.

We also searched the GISAID website and websites of the following public health agencies: Health Security Agency (UKHSA) of the United Kingdom, Centers for Disease Control and Prevention of the United States of America (USCDC), Statens Serum Institute (SSI) of Denmark, the National Institute for Communicable Diseases (NICD) of South Africa and the European Centre for Disease Prevention and Control (ECDC).

The summary of the evidence was done based on the risk assessment framework implemented by the UKHSA. Following the assessment, each indicator was assigned one of four colours: red, amber, yellow and green. Red implies a difference

in the indicator between BA.2 and BA.1. Amber implies there is a difference in the indicator between BA.2 and BA.1 in certain population subgroups. Yellow implies there is limited evidence suggesting a difference in the indicator between BA.2 and BA.1. Green implies there is no difference in the indicator between BA.2 and BA.1. Grey implies there is insufficient data on the indicator. The confidence grading was classified as: “Low” when there was little or poor-quality evidence, uncertainty or conflicting views amongst experts or no experience with previous similar incidents; “Moderate” when there was adequate quality evidence – including consistent results published only in grey literature, reliable source(s), assumptions made on analogy and agreement between experts or opinion of at least 2 trusted experts; and “High” when there was good quality evidence, multiple reliable sources, verified, expert opinion concurs, and experience of previous similar incidents.

Annex 4. Methods for Figures 6 and 7

• Figures include six studies from Denmark, Qatar, South Africa, the United Kingdom, and the United States of America evaluating the VE against the Omicron variant, and 20 studies of the VE against the Delta variant from various countries from the European Region and Region of the Americas, as well as Qatar, Malaysia and Singapore.

• VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when either Delta or Omicron was the predominant circulating variant. Estimates were included if they were of laboratory-confirmed cases of the Omicron or Delta variant. In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.

• For the primary series VE, estimates are only included in the plot for studies that report VE for more than one time period.

Annex 5. Summary of primary series vaccine performance against Variants of Concern (data as of 18 February 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺								Vaccines without WHO EUL ⁺	
	AstraZeneca-Vaxzevria/SII - Covishield	Beijing CNBG-BBIBP-CorV	Bharat-Covaxin	Janssen-Ad26.COV 2.S	Moderna-mRNA-1273	Novavax-Nuvaxovid/SII - Covavax	Pfizer BioNTech-Comirnaty	Sinovac-CoronaVac	Anhui ZL-Recombinant	Gamaleya-Sputnik V
Alpha, Beta, Gamma										
Summary of VE*	(see update from 11 January 2022 for details of vaccine performance against Alpha, Beta, and Gamma variants of concern									
Delta ³⁷										
Summary of VE*	Protection retained against severe disease; possible reduced protection against symptomatic disease and infection									
- Severe disease	↔ ₃	-	-	↓ ₁	↔ ₄	-	↔ ₇	-	-	-
- Symptomatic disease	↔to↓ ₆	-	↓ ₁	-	↔ ₂	-	↔to↓ ₅	-	-	-
- Infection	↔to↓ ₅	-	-	↓↓↓ ₁	↔ ₆	-	↔to↓ ₆	-	-	-
Neutralization	↓ ₁₄	↔to↓ ₂	↔to↓ ₄	↔to↓↓ ₁₀	↓ ₁₄	-	↔to↓ ₄₀	↓to↓↓ ₉	↔to↓ ₂	↓to↓↓↓ ₃
Omicron										
Summary of VE*	Reduced protection against infection and symptomatic disease; possible reduced protection against for severe disease but limited evidence									
- Severe disease	-	-	-	-	↓/↓↓ ₁	-	↓↓/↓↓↓ ₃	-	-	-
- Symptomatic disease	↓↓↓ ₁	-	-	-	↓↓/↓↓↓ ₂	-	↓↓↓ ₂	-	-	-
- Infection	↓↓↓ ₁	-	-	-	↓↓↓ ₃	-	↓↓↓ ₃	-	-	-
Neutralization	↓↓↓ ₆	↔to↓↓↓ ₃	↓↓ ₁	↔to↓↓ ₄	↓↓↓ ₁₆	-	↓↓↓ ₃₄	↓to↓↓↓ ₄	-	↓↓ ₁

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](https://view-hub.org). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table. + Severe disease is defined differently across studies and may include outcomes such as hospitalization, critical disease, and other forms of ‘severe’ disease.

Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean a loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Annex 5 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than four months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (\geq seven days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase three randomized controlled trial (RCT) results from non-VOC settings. For severe disease and infection, due to instability or lack of phase three RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase three estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected $>$ seven days and $<$ six months after complete vaccination and that use an ancestral strain as the reference are included in Annex 5.

COVID-19 Weekly Epidemiological Update

Edition 79, published 15 February 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [Special Focus: Update on the Pango Lineage BA.2 of the Omicron variant of concern](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 13 February 2022

Globally, during the week of 7 to 13 February 2022, the number of new COVID-19 cases decreased by 19% as compared to the number reported during the previous week, while the number of new deaths remained similar to that of the previous week (Figure 1). Across the six WHO regions, just over 16 million new cases and just under 75 000 new deaths were reported (Table 1). As of 13 February 2022, over 409 million confirmed cases and over 5.8 million deaths have been reported globally.

At the regional level, the Western Pacific Region reported an increase of 19% in the number of new weekly cases while all other regions reported decreases: the South-East Asia Region (37% decrease), the Region of the Americas (32% decrease), the African Region (30% decrease), the European Region (16% decrease) and the Eastern Mediterranean Region (12% decrease). The number of new weekly deaths increased in the Eastern Mediterranean Region (38%), the Western Pacific Region (27%), the African Region (14%) and the Region of the Americas (5%), while it remained similar to that of the previous week in the European Region and decreased in the South-East Asia Region (9%).

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 13 February 2022**

**See [Annex 2: Data, table, and figure notes](#)

The highest numbers of new cases were reported from the Russian Federation (1 323 391 new cases; a 23% increase), Germany (1 322 071 new cases; similar to the previous week's figures), the United States of America (1 237 530 new cases; a 43% decrease), Brazil (1 009 678 new cases; a 19% decrease), and France (979 228 new cases; a 43% decrease). The highest number of new deaths were reported from the United States of America (17 225 new deaths; similar to the previous week's figures), India (6686 new deaths; a 15% decrease), Brazil (6658 new deaths; a 44% increase), the Russian Federation (4834 new deaths; similar to the previous week's figures) and Mexico (2530 new deaths; a 7% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 13 February 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	9 595 045 (60%)	-16%	164 431 350 (40%)	24 817 (33%)	1%	1 815 834 (31%)
Americas	3 236 405 (20%)	-32%	142 966 356 (35%)	33 722 (45%)	5%	2 570 792 (44%)
Western Pacific	1 569 099 (10%)	19%	18 859 407 (5%)	3 087 (4%)	27%	172 864 (3%)
South-East Asia	915 448 (6%)	-37%	54 278 257 (13%)	7 983 (11%)	-9%	752 524 (13%)
Eastern Mediterranean	712 632 (4%)	-12%	20 349 089 (5%)	3 286 (4%)	38%	326 795 (6%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential Variants of Concern (VOCs), Variants of Interest (VOIs) or Variants under Monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

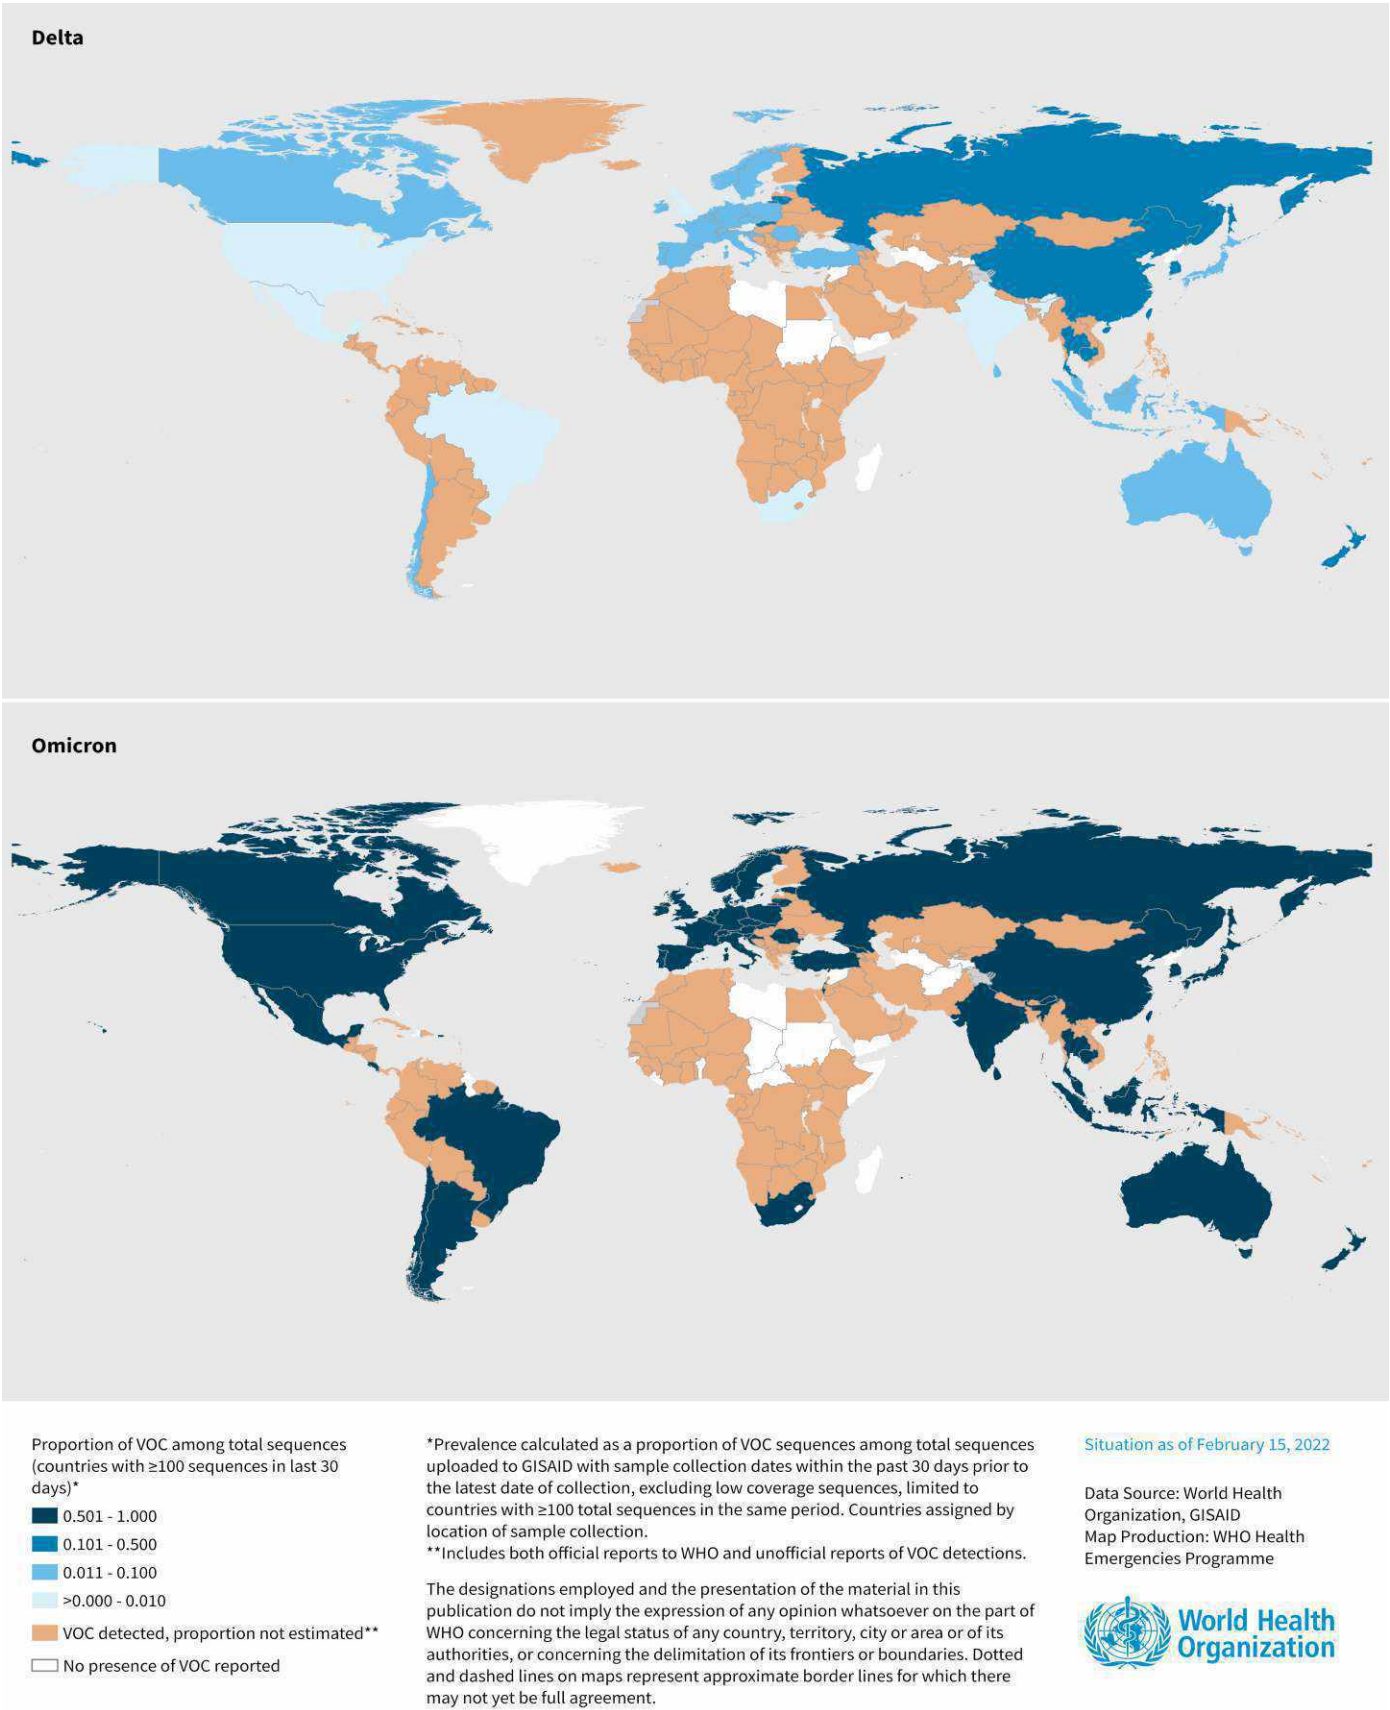

The current global epidemiology of SARS-CoV-2 is characterized by the global dominance of the Omicron variant. All other variants, including VOCs (Alpha, Beta, Gamma and Delta) and VOIs (Lambda and Mu) continue to decline in all six WHO regions. Among the 432 470 sequences uploaded to [GISAID](#) with specimens collected in the last 30 days¹, 425 227 (98.3%) were Omicron, 7 191 (1.7%) were Delta and one (<0.1%) was Lambda. During this same period, there were no Alpha, Beta, Gamma or Mu sequences reported. To note, global VOCs and VOIs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Special Focus: Update on BA.2 Pango lineage of the Omicron variant of concern

Since the designation of B.1.1.529 as a VOC on 26 November 2021, several lineages have been identified. These include Pango lineages BA.1, BA.1.1, BA.2 and BA.3, which are all being monitored by WHO under the umbrella of 'Omicron'.

Recent data on BA.2 is summarised based on a targeted literature search and an assessment based on the framework applied by the UK Health Security Agency (UKHSA).¹ The Annex 3 provides further information on how the evidence was gathered and appraised.

Epidemiology

The prevalence of BA.2 among sequenced Omicron cases globally submitted to GISAID has been steadily increasing,² reaching 21.09% in week 5 of 2022.³ As of 14 February, 10 countries reported a predominance of BA.2 (>50%): Bangladesh, Brunei Darussalam, China, Denmark, Guam, India, Montenegro, Nepal, Pakistan, Philippines. However, there are differences between regions observed, with the South-East Asia Region reporting the highest prevalence of BA.2 among Omicron sequences (44.7%) and the Region of the Americas reporting the lowest prevalence (1%). This analysis is based on all sequences submitted to GISAID with samples collected from 13 January to 11 February 2022. These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as laboratory turn-around times for sequencing and delays in reporting. Additionally, it is important to consider the relative proportions of the BA.2 sequences in the context of the case incidence when interpreting the spread and relative growth of different lineages.

Examples of countries which have seen an increase in the prevalence of BA.2 include: South Africa where the prevalence rose from 27% on 4 February 2022⁴ to 86% by 11 February 2022⁵; the United Kingdom⁶ where the prevalence increased six-fold from 17 to 31 January 2022 (from 2.2% to 12%); Denmark where the prevalence doubled from week 52 of 2021 to week 2 of 2022 (from 20% to 45%) and became the dominant variant (66% of sequenced by week 3 of 2022⁷) and the United States of America where the prevalence tripled from 1.2% during the week ending 29 January 2022 to 3.6% during the week ending 5 February 2022.⁸ The prevalence of BA.2 appears to be increasing both in countries experiencing a decline in Omicron cases and in countries that are in the growing phase of the wave.

Transmission

Early evidence from limited studies suggests BA.2 is more transmissible as compared to BA.1. Estimates of growth rates in Denmark indicate that BA.2 is 30% more transmissible than BA.1.⁷ An analysis of GISAID data⁹ shows a growth rate advantage of BA.2 over BA.1 in all 43 countries with sufficient sequence data and co-circulation of the two lineages, translating to a pooled mean transmission advantage (i.e. relative difference in effective reproduction numbers) of 84% (95% CI: 68% – 101%) across epidemiological contexts under the assumption of an unchanged generation time.

Currently available evidence on the secondary attack rate (SAR) among contacts of BA.2 compared to BA.1 was obtained from household transmission studies in Denmark and the United Kingdom. Danish researchers¹⁰ found higher SAR for BA.2 compared to BA.1 at one (8% vs 6%), seven (39% vs 29%) and 14 (42% vs 36%) days of follow-up. Similar results were reported in the United Kingdom⁶ with a higher SAR for BA.2 (13.4%; 95% CI: 10.7%-16.8%) compared to BA.1 (10.3%; 95% CI: 10.1%-10.4%). These estimates are likely to change over time as more data become available.

It is currently unclear what factors drive the growth advantage of BA.2 over BA.1. Preliminary data¹¹ show similar antibody responses to BA.1 and BA.2. This supports findings from a household transmission study¹⁰ conducted in Denmark, in which unvaccinated primary cases infected with BA.2 were more likely to transmit to household contacts when compared to BA.1. The increase in proportion of BA.2 relative to BA.1 in contexts with decreasing case numbers also supports increased transmissibility of BA.2 in comparison to BA.1, rather than immune evasion.

Diagnostic testing

In contrast to Omicron Pango lineages BA.1 and BA.1.1, the BA.2 Pango lineage does not have the 69-70 deletion in the Spike protein which is responsible for S-gene target failure (SGTF) on certain PCR assays. The presence of SGTF was previously considered to screen for Omicron, enabling a proxy to distinguish between BA.1 and other VOCs, such as Delta, in the absence of sequencing. In settings where Omicron is the dominant circulating variant, employing this screening approach could enable some distinction between BA.1 (SGTF) and BA.2 in which the result would be S-gene target positive (SGTP).⁶ This approach is only possible in settings where the prevalence of Omicron is very high and it should be noted that sequencing is the only way to definitively confirm a particular variant.

Following analysis of publicly available sequences, several antigen, antibody and PCR tests were found to perform equally well in detecting SARS-CoV-2 infections caused by BA.1 and BA.2.¹² Another study found differences in sensitivity of various PCR assays in detecting BA.1 and BA.2 Pango lineages (from 0% to 100%).¹³ Further studies are underway to fully understand the impact of Omicron Pango lineages on diagnostic assays.

There are other mutations/deletions in Omicron that may overlap with primer or probe targets of commercially available PCR kits, leading to target failure. One example includes a report in which N-gene target failure (NGTF) has been reported for one assay in individuals with sequence-confirmed infection with Omicron variant (including BA.1 and BA.2) due to the lineage-defining ERS31-33 deletion, but not in those infected with the Delta variant.¹⁴ This implies that multigene PCR assays which target this region of the N gene may be considered as a way to screen for Omicron (NGTF) to distinguish it from other VOCs, including Delta (NGTP) in settings where there is incomplete replacement of Delta by Omicron.

Disease severity

At present, there is limited evidence on the severity of BA.2 relative to BA.1 or other Omicron Pango lineages. As the proportion of BA.2 has steadily increased in recent weeks in the United Kingdom, there has been a consistent decrease in the number of hospitalizations and deaths.¹⁵ In the United States of America,⁸ there have been decreases in hospitalizations and increases in the number of deaths across successive weeks. In this context, a 5.9% reduction in the number of new deaths was reported during the week ending 8 February 2022 as compared to the previous week ending 1 February 2022. However, this does not allow inferences to be made as to the relative severity of BA.2 as in both these countries, BA.1 or BA.1.1 was the dominant Pango lineage during this period.

An analysis conducted in Denmark showed no difference in risk of hospitalisation between those infected with BA.2 and those infected with BA.1, although as BA.2 has become the dominant variant, there has been a recent rise in the number of hospitalisations and deaths in the country.¹⁶ In Nepal, as published on 1 February 2022, ten of eleven samples sequenced at Kathmandu University, Nepal were of the BA.2 lineage.¹⁷ However, the number of patients in hospital in the Kathmandu Valley has been decreasing since a peak on 23 January 2022 with the numbers in intensive care and on mechanical ventilation also showing some initial signs of a decrease. In South Africa, BA.2 now accounts for 86% of all sequences; however, hospital admissions continue to decline.¹⁸

Overall, there is no difference in severity when looking at countries where BA.2 is dominant and those where BA.1 is dominant.

Impact on immunity:

- **Neutralization**

A preprint study including eight individuals with a history of SARS-CoV-2 infection and 24 individuals who had received primary series vaccination and a booster with Pfizer BioNTech-Comirnaty showed similar neutralizing antibody titres to BA.1 and BA.2.¹¹

- **Vaccination**

Preliminary results from a test-negative case control study in the United Kingdom found no difference in vaccine effectiveness against symptomatic disease between BA.1 and BA.2 25 weeks after two doses of the primary series (9% [95%CI: 7-10] vs 13% [95%CI: -26-40]) or two weeks after an additional booster vaccine dose (63% [95%CI: 63-64] vs 70% [95%CI: 58-79]).¹⁹

Preliminary results from a household transmission study conducted in Denmark showed that primary cases infected with BA.2 who had received two doses of vaccine (OR = 0.60; 95%CI: 0.42-0.85) and primary cases infected with BA.2 who had received a booster dose (OR = 0.62; 95%CI: 0.42-0.91) were less likely to infect household contacts compared to primary cases infected with BA.1. There was no difference in susceptibility for vaccinated and unvaccinated household contacts of primary cases who were infected with either BA.1 or BA.2. This suggests that vaccination is at least equally effective in preventing acquisition of BA.2 and could be more effective in preventing transmission of BA.2 compared to BA.1.

Treatment

There is currently insufficient evidence on differences in efficacy of treatment options for BA.2 compared to other Omicron Pango lineages.

Summary

Summary assessment of evidence on BA.2 compared to BA.1

Indicator	Assessment	Confidence level	Rationale for assessment
Transmissibility	Red	Moderate	Evidence from Denmark and the UK indicating higher growth rates of BA.2 when compared to BA.1. ⁷
Disease severity	Green	Low	No evidence of increase in severity of BA.2 relative to BA.1
Immune escape	Green	Moderate	Similar vaccine effectiveness on BA.2 and BA.1. Comparable neutralizing antibody titres against BA.1 and BA.2 in both previously infected and booster vaccinated individuals
Impact on detection capacity	Green	Low	No difference in diagnostic accuracy of some PCR, antigen and antibody tests that were assessed.
Impact on therapeutics			Insufficient data on differences in effectiveness of current treatments between BA.2 and other Pango lineages

*Refer to the UKHSA [framework](#) on risk assessment for SARS-CoV-2 variants and Annex 3.

African Region

The African Region reported a continued decrease in the number of cases since the beginning of January with over 69 000 new cases reported, a 30% decrease as compared to the previous week. However, four countries reported an increase of over 20% in cases; Congo (130 vs 25 new cases; a 420% increase), Liberia (82 vs 22 new cases; a 273% increase), Lesotho (114 vs 82; a 39% increase) and Central African Republic (131 vs 104; a 26% increase). The highest numbers of new cases were reported from Réunion (30 782 new cases; 3438.1 new cases per 100 000 population; a 32% decrease), South Africa (17 952 new cases; 30.3 new cases per 100 000; a 13% decrease), and Algeria (3628 new cases; 8.3 new cases per 100 000; a 56% decrease).

The African Region reported just under 1600 new deaths, a 14% increase as compared to the previous week. The highest numbers of new deaths were reported from South Africa (1168 new deaths; 2.0 new deaths per 100 000 population; a 28% increase), Algeria (75 new deaths; <1 new death per 100 000; a 12% decrease), and Ethiopia (65 new deaths; <1 new death per 100 000; a 124% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 3.2 million new cases, a 32% decrease as compared to the previous week, a trend that has continued since mid-January. However, ten countries reported increases in new cases of 20% or greater, with the highest proportional increases reported from the Falkland Islands (seven vs two new cases; an 250% increase), Antigua and Barbuda (559 vs 174 new cases; a 244% increase) and Haiti (358 vs 105 new cases; a 241% increase). The highest numbers of new cases were reported from the United States of America (1 237 530 new cases; 373.9 new cases per 100 000; a 43% decrease), Brazil (1 009 678 new cases; 475.8 new cases per 100 000; a 19% decrease) and Chile (247 900 new cases; 1296.8 new cases per 100 000; a 9% increase).

The Region reported over 33 000 new deaths this week, a 5% increase as compared to the previous week. The highest numbers of new deaths were reported from the United States of America (17 225 new deaths; 5.2 new deaths per 100 000; similar to the previous week's figures), Brazil (6658 new deaths; 3.1 new deaths per 100 000; a 44% increase) and Mexico (2530 new deaths; 2.0 new deaths per 100 000; a 7% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 712 000 new cases this week, a 12% decrease as compared to the previous week. This is the first reported decline in incidence following weekly increases from early December 2021. An increase of over 20% in new cases was reported by two countries: Yemen (415 vs 251 new cases; a 65% increase) and the Syrian Arab Republic (800 vs 542 new cases; 48%). The highest numbers of new cases were reported from the Islamic Republic of Iran (236 616 new cases; 281.7 new cases per 100 000; a 7% increase), Jordan (136 567 new cases; 1338.5 new cases per 100 000; a 17% increase), and Lebanon (46 417 new cases; 680.1 new cases per 100 000; a 20% decrease).

Over 3200 new deaths were reported in the Region this week, a 38% increase as compared to the previous week. The highest numbers of new deaths were reported from the Islamic Republic of Iran (825 new deaths; 1.0 new death per 100 000; a 126% increase), Tunisia (453 new deaths; 3.8 new deaths per 100 000; an 18% increase), and Egypt (415 new deaths; <1 new death per 100 000; a 33% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported just under 9.6 million new cases, a 16% decrease as compared to the previous week, the second consecutive week of a decline in the number of new cases since the peak observed at the end of January. However, four countries reported increases of 20% or greater over the past week; Belarus (53 969 vs 30 475 new cases; a 77% increase), the Netherlands (877 154 vs 561 539 new cases; a 56% increase), Iceland (13 802 vs 9797 new cases; a 41% increase) and the Russian Federation. The highest numbers of new cases were reported from the Russian Federation (1 323 391 new cases; 906.8 new cases per 100 000; a 23% increase), Germany (1 322 071 new cases; 1589.7 new cases per 100 000; similar to the previous week's figures), and France (979 228 new cases; 1505.6 new cases per 100 000; a 43% decrease).

The European Region reported over 24 000 new deaths, similar to the previous week's figures. The highest numbers of new deaths were reported from the Russian Federation (4834 new deaths; 3.3 new deaths per 100 000; similar to the previous week's figures), Italy (2282 new deaths; 3.8 new deaths per 100 000; a 13% decrease), and France (2270 new deaths; 3.5 new deaths per 100 000; a 23% increase).

Updates from the [European Region](#)

South-East Asia Region

The number of new weekly cases has continued to decline in the South-East Asia Region since mid-January, with over 915 000 new cases reported, a 37% decrease as compared to the previous week. This week, four countries reported increases of 20% or greater: Myanmar (8870 vs 2647 new cases; a 235% increase), Timor-Leste (1228 vs 466 new cases; a 164% increase), Indonesia (291 298 vs 173 295 new cases; a 68% increase), and Thailand (96 326 vs 64 467 new cases; a 49% increase). The highest numbers of new cases were reported from India (443 283 new cases; 32.1 new cases per 100 000; a 60% decrease), Indonesia (291 298 new cases; 106.5 new cases per 100 000; a 68% increase), and Thailand (96 326 new cases; 138.0 new cases per 100 000; a 49% increase).

Over 7900 new deaths were reported in the Region this week, a 9% decrease as compared to the previous week. The highest numbers of new deaths were reported from India (6686 new deaths; <1 new death per 100 000; a 15% decrease), Indonesia (622 new deaths; <1 new death per 100 000; a 148% increase), and Bangladesh (230 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 1.5 million new cases, a 19% increase as compared to the previous week. Half of the countries (14/28) and territories of the Region reported increases in new cases of 20% or greater, with the highest proportional increases reported from Tonga (62 vs 10 new cases; a 520% increase), China (7571 vs 1787 new cases; a 324% increase), and Brunei Darussalam (4175 vs 1059 new cases; a 294% increase). The highest numbers of new cases were reported from Japan (624 240 new cases; 493.6 new cases per 100 000; similar to the previous week's figures), the Republic of Korea (340 950 new cases; 665.0 new cases per 100 000; an 88% increase), and Australia (162 079 new cases; 635.6 new cases per 100 000; a 25% decrease).

There was a 27% increase in the number of new deaths as compared to the previous week, with over 3000 new deaths reported in the Region. The highest numbers of new deaths were reported from Japan (945 new deaths; <1 new death per 100 000; a 79% increase), the Philippines (716 new deaths; <1 new death per 100 000; a 109% increase), and Viet Nam (601 new deaths; <1 new death per 100 000; a 16% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 15 February, highlights include the following:

- Strengthening South Sudan's emergency response with phase two of public health emergency operations center
- Romania: boosting the mobility of health-care workers to support communities during the pandemic and beyond
- WHO and the Syrian Arab Republic combine efforts to raise COVID-19 vaccine accessibility and uptake
- Maintaining influenza surveillance and SARS-CoV-2 monitoring in Indonesia
- Online courses in Ukrainian support national response to the COVID-19 pandemic and other emergencies
- Updates on WHO's financing to support countries on COVID-19 response implementation to suppress transmission, reduce exposure, and protect the vulnerable and save lives
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

tes that information for this variant was received by WHO from of
was received by WHO from
*unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.*
See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 3. Methods for the update on BA.2 Pango lineage of the Omicron variant of concern

We conducted a search for published and unpublished studies on the BA.2 Pango lineage of the Omicron variant. The search for published studies was conducted in Medline while the search for unpublished literature was conducted in MedRxiv, which is a repository for preprints. We searched for studies and reports with an abstract in English, that were accessible up to 14 February 2022. Search terms used were “BA.2” and “Omicron Pango lineages”.

We also searched the GISAID website and websites of the following public health agencies: Health Security Agency (UKHSA) of the United Kingdom, Centers for Disease Control and Prevention of the United States of America (USCDC), Statens Serum Institute (SSI) of Denmark, the National Institute for Communicable Diseases (NICD) of South Africa and the European Centre for Disease Prevention and Control (ECDC).

The summary of the evidence was done based on the risk assessment framework implemented by the UKHSA. Following the assessment, each indicator was assigned one of four colours: red, amber, yellow and green. Red implies a difference in the indicator between BA.2 and BA.1. Amber implies there is a difference in the indicator between BA.2 and BA.1 in

certain population subgroups. Yellow implies there is limited evidence suggesting a difference in the indicator between BA.2 and BA.1. Green implies there is no difference in the indicator between BA.2 and BA.1. Grey implies there is insufficient data on the indicator. The confidence grading was classified as: “Low” when there was little or poor-quality evidence, uncertainty or conflicting views amongst experts or no experience with previous similar incidents; “Moderate” when there was adequate quality evidence - including consistent results published only in grey literature, reliable source(s), assumptions made on analogy and agreement between experts or opinion of at least 2 trusted experts; and “High” when there was good quality evidence, multiple reliable sources, verified, expert opinion concurs, and experience of previous similar incidents.

COVID-19 Weekly Epidemiological Update

Edition 78, published 8 February 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 6 February 2022

Globally, during the week of 31 January to 6 February 2022, the number of new COVID-19 cases decreased by 17% as compared to the number reported during the previous week, while the number of new deaths increased by 7% (figure 1). Across the six WHO regions, over 19 million new cases and just under 68 000 new deaths were reported (table 1). As of 6 February 2022, over 392 million confirmed cases and over 5.7 million deaths have been reported globally.

At the regional level, the Eastern Mediterranean Region reported an increase of 36% in the number of new weekly cases while all other regions reported decreases: The Region of the Americas (36%), the South-East Asia Region (32%), the African Region (22%), the Western Pacific Region (8%) and the European Region (7%). The number of new weekly deaths continued to increase in the South-East Asia (67%) and Eastern Mediterranean Regions (45%), while the number remained similar to that of the previous week in the Region of the Americas and the European Region and decreased in the African (14%) and Western Pacific Regions (5%).

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 6 February 2022**

**See [Annex 2: Data, table, and figure notes](#)

At the country level, the highest numbers of new cases were reported from the United States of America (1 874 006 new cases; a 50% decrease), France (1 738 189 new cases; a 26% decrease), Germany (1 285 375 new cases; a 22% increase), Brazil (1 241 025 new cases; similar to the previous week's figures) and India (1 095 616 new cases; a 41% decrease). The highest number of new deaths were reported from the United States of America (14 090 new deaths; a 15% decrease), India (7888 new deaths; a 69% increase), the Russian Federation (4686 new deaths; similar to the previous week's figures), Brazil (4610 new deaths; an 39% increase) and Mexico (2910 new deaths; a 48% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 6 February 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	11 106 661 (58%)	-7%	154 414 207 (39%)	23 446 (35%)	2%	1 789 169 (31%)
Americas	4 487 367 (23%)	-36%	139 283 017 (36%)	29 560 (44%)	0%	2 531 968 (44%)
South-East Asia	1 452 690 (8%)	-32%	53 362 809 (14%)	8 761 (13%)	67%	744 541 (13%)
Western Pacific	1 323 186 (7%)	-8%	17 291 386 (4%)	2 427 (4%)	-5%	169 777 (3%)
Eastern Mediterranean	808 497 (4%)	36%	19 636 359 (5%)	2 357 (3%)	45%	323 481 (6%)
Africa	98 071 (1%)	-22%	8 157 159 (2%)	1 402 (2%)	-14%	165 404 (3%)
Global	19 276 472 (100%)	-17%	392 145 701 (100%)	67 953 (100%)	7%	5 724 353 (100%)

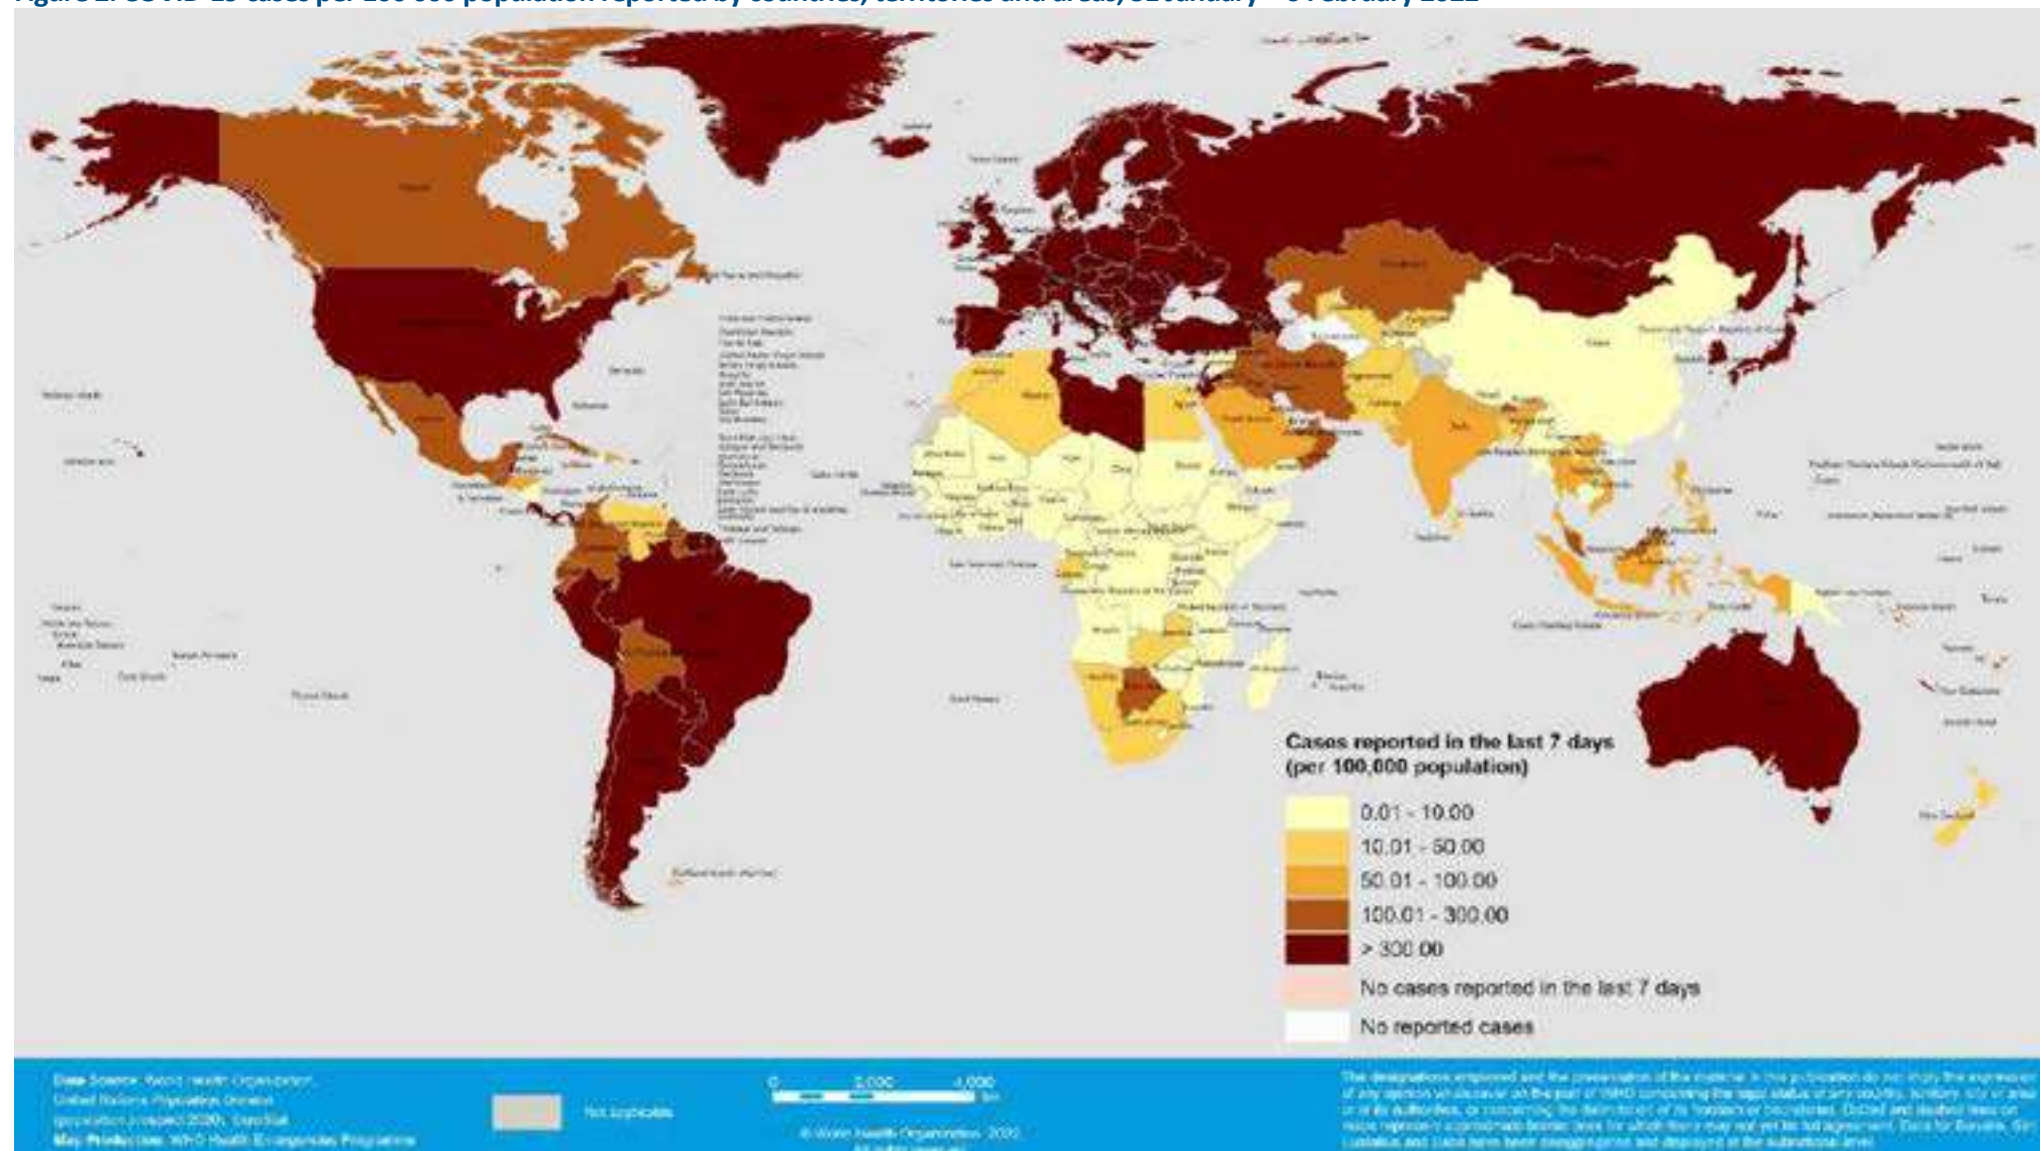

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the continued rapid global spread of the Omicron variant. All other variants, including VOCs (Alpha, Beta, Gamma and Delta) and VOIs (Lambda and Mu) continue to decline in all six WHO regions. Among the 426 363 sequences uploaded to [GISAID](#) with specimens collected in the last 30 daysⁱ, 412 265 (96.7%) were Omicron, 13 972 (3.3%) were Delta, two (<0.1%) were Gamma, and two (<0.1%) were Alpha. There were no sequences reported for any other variant, including for VOIs Mu and Lambda. To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

The spread and prevalence of the Omicron variant

Since the designation of B.1.1.529 as a VOC on 26 November 2021, several lineages have been identified. These include Pango lineages BA.1, BA.1.1, BA.2 and BA.3, which are all being monitored by WHO under the umbrella of 'Omicron'. BA.2 shares many mutations with BA.1, but also has a number of differences, including in the Spike protein – critically, it does not carry the Spike 69-70 deletion associated with S-gene target failure, used as a proxy for detecting BA.1, BA.1.1, B.1.1.529 and BA.3. BA.1.1 carries an additional R346K mutation, which is suspected to provide additional immune escape potential.

Most of the current evidence describing the phenotypic characteristics of the Omicron variant is based on the BA.1 Pango lineage. However, a relative increase in the BA.2 lineage has been observed in multiple countries and investigations into the characteristics of BA.2, including its transmissibility, immune escape properties and virulence, need to be prioritized independently (and comparatively) to BA.1 ([WHO Tracking SARS-CoV-2 variants website](#)). Additionally, it is important to consider the relative proportions of the BA.1 and BA.2 sequences in the context of the case incidence when interpreting the spread and relative growth of different lineages.

The prevalence of the Omicron variant has increased globally and is now detected in almost all countries. However, many of the countries which reported an early rise in the number of cases due to the Omicron variant have now reported a decline in the total number of new cases since the beginning of January 2022. Figure 4, plot A shows a decrease in the proportion of BA.1 sequences compared to the other lineages since epidemiological week 2 (10-16 January 2022) with a proportional increase in BA.1.1 and BA.2 sequences. Figure 4, plot B shows an increase in the

ⁱ Includes sequences submitted to with sample collected dates from 7 January to 5 February 2022 (last reported sample at the time of data extraction, excluding low coverage sequences)

number of sequences of the Omicron lineages submitted to GISAID in December 2021 and a decrease since the beginning of January 2022. This global trend has been observed in several countries, including some with high sequencing capacity; the pattern may be different in others. These trends should be interpreted with due consideration of the limitations of surveillance systems, including differences in sequencing capacity and sampling strategies between countries, as well as laboratory turn-around times for sequencing and delays in reporting.

Figure 4. Global distribution and relative proportion of Omicron lineages for sequences submitted to GISAID presented by epidemiological week of specimen collection

Global distribution of Omicron lineages from sequences and metadata submitted to GISAID.

Panel A. Relative proportions of Omicron lineages over the last 4 weeks by specimen collection week.

Panel B. Incidence of Omicron lineages by week of specimen collection.

Data was extracted from GISAID on 8 February 2022 at 14:00 CET; figures are correct at the time of printing.

WHO continues to monitor circulating and emerging variants and to identify and address relevant knowledge gaps through the development of coordinated, multi-layered surveillance, preparedness, and response strategies for addressing COVID-19.

Differences in the phenotypic characteristics of VOCs

Available evidence on the phenotypic impacts of the VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the 25 January 2022 update there are several new publications on the phenotypic characteristics of VOCs, including recent literature on the Omicron variant. Some of the studies reported have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Detailed information on Omicron variant and related recommended priority actions for Member States can be found in the updated Technical Brief and Priority Actions for Member States which can be found under the [Country and Technical Guidance – Coronavirus Disease \(COVID-19\)](#). Based on the currently available evidence, the overall risk related to the Omicron variant remains very high.

Table 2: Summary of phenotypic impacts* of variants of concern

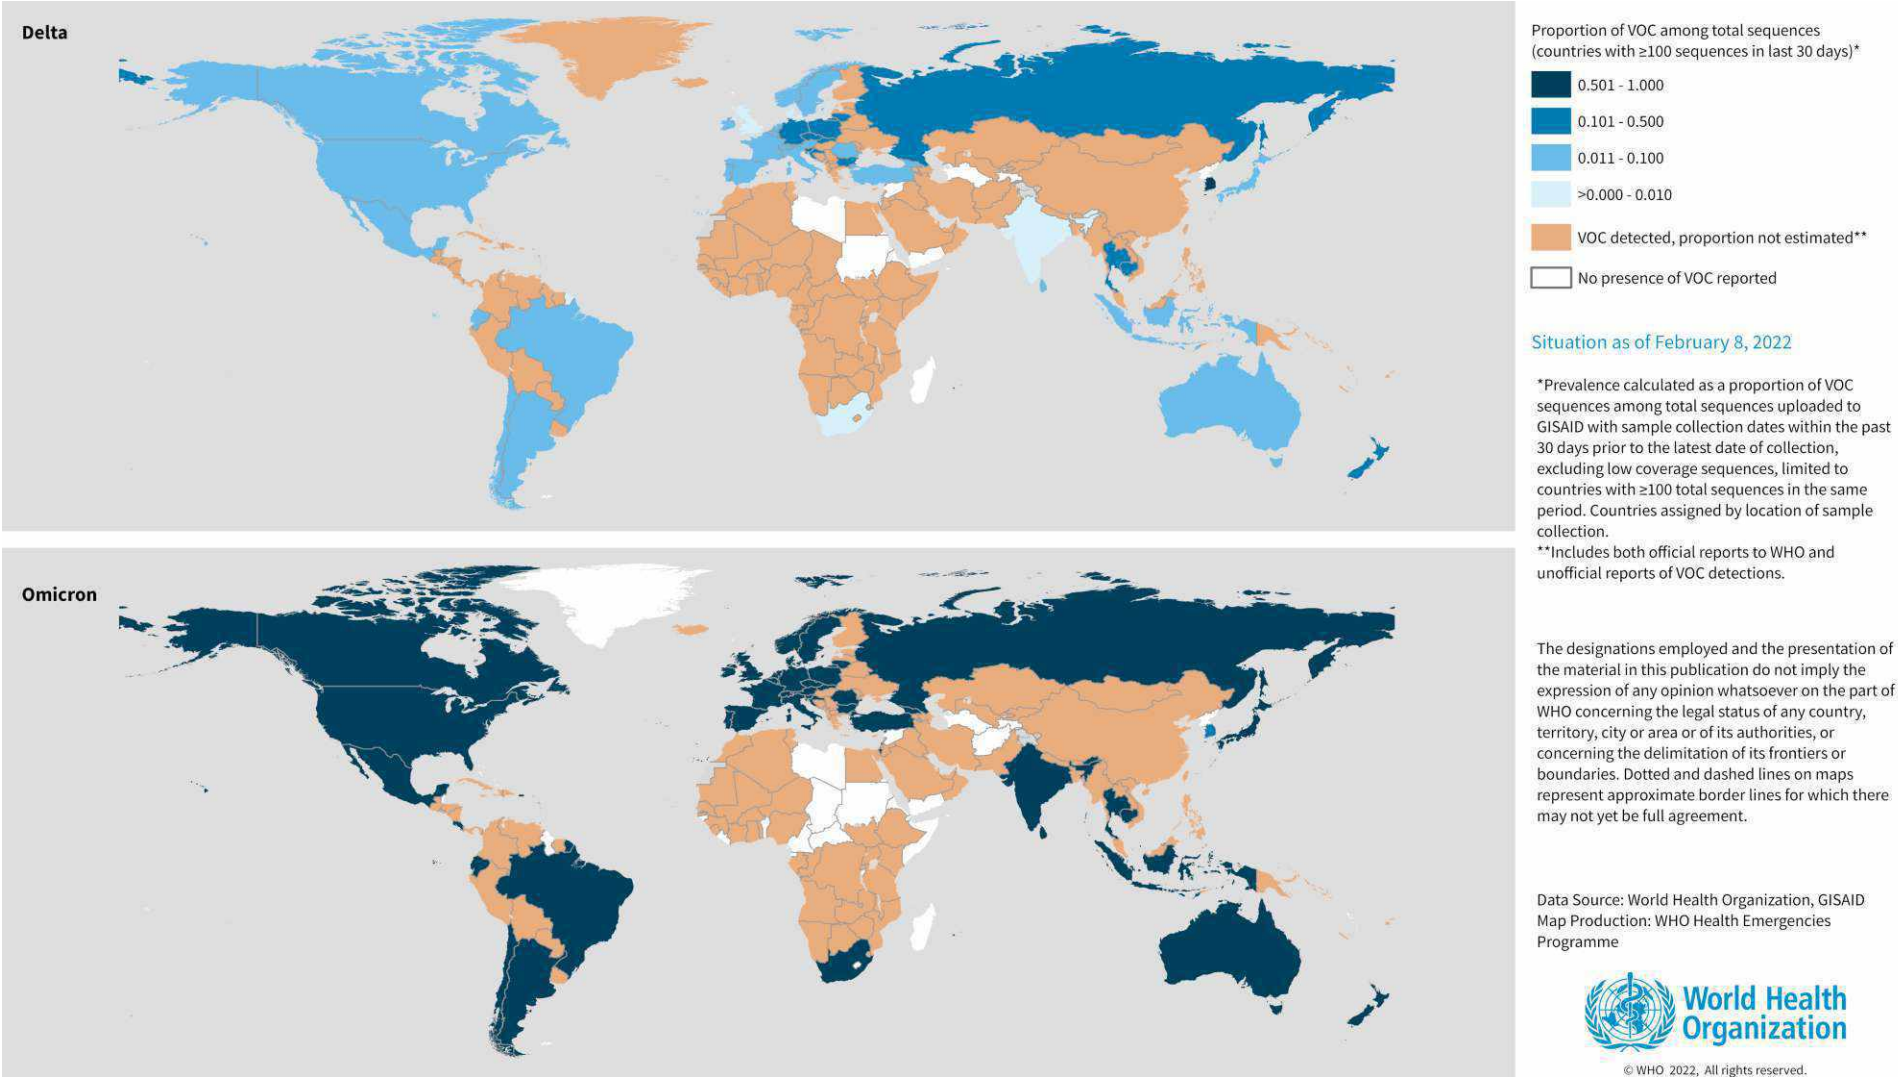

WHO label	Alpha	Beta	Gamma	Delta	Omicron
Transmissibility	Increased transmissibility ¹	Increased transmissibility ^{2,3}	Increased transmissibility ^{3,4}	Increased transmissibility ^{3,5,6}	Increased transmissibility. ^{7–10}
Disease severity	Possible increased risk of hospitalization ^{11,12} , possible increased risk of severe disease and death ^{13,14}	Possible increased risk of hospitalization ¹² , possible increased in-hospital mortality ¹⁵	Possible increased risk of hospitalization ¹² , possible increased risk of severe disease ¹⁶	Possible increased risk of hospitalization ^{17,18}	Reduced risk of hospitalization and severe disease ^{19–22}
Risk of reinfection	Neutralizing activity retained ²³ , risk of reinfection remains similar ²⁴	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²⁵	Moderate reduction in neutralizing activity reported ²⁶	Reduction in neutralizing activity reported ^{27–29}	Increased risk of reinfection ^{30,31}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ³²	No impact on RT-PCR or Ag RDTs observed ²⁹	None reported to date	No impact on RT-PCR or Ag RDTs observed ³³	PCR continues to detect Omicron. Impact on Ag-RDTs is under investigation: Results are mixed as to whether or not there may be decreased sensitivity to detect Omicron. 7,22,34–36

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

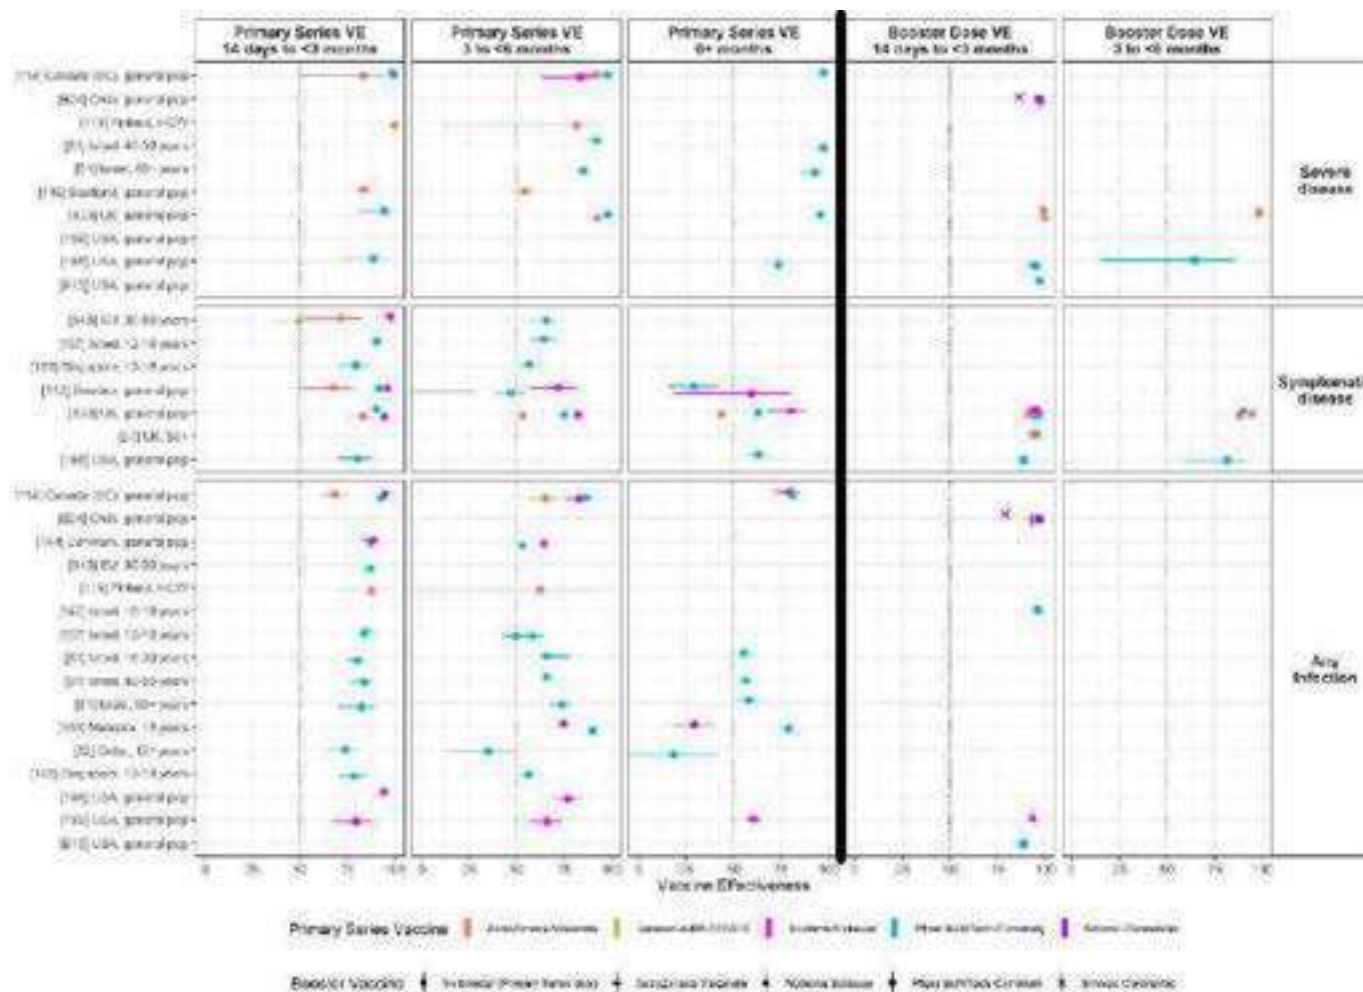

Figure 5. Prevalence of variants of concern (VOCs) Delta and Omicron in the last 30 days, data as of 8 February 2022

See also [Annex 2](#) for reported VOC detections by country/territory/area

Figure 6. Vaccine effectiveness (VE) of primary series and booster vaccination against the Omicron variant of concern

Abbreviations: pop=population; HCW=healthcare workers; EU=European Union. Dots represent point estimates of vaccine effectiveness; horizontal lines represent the 95% confidence intervals. Labels along left side of plot indicate reference numbers [], country, and study population. Reference numbers identify the study and link to the [summary table](#) of VE effectiveness studies on [view.hub.org](#) (Table 1 in summary table); references starting with a 'B' are studies found in the booster VE table only (Table 2 in summary table). Primary series refers to the completion of two doses of vaccines for Astra-Zeneca-Vaxzevria; Moderna-Spikevax, Pfizer BioNTech-Comirnaty and Sinovac-CoronaVac and one dose of Janssen-Ad26.COV2.S. Severe disease includes hospitalization; symptomatic disease includes both mild and severe disease; any infection includes both asymptomatic infections and any symptomatic disease. Additional details on the methods for inclusion of the estimates in the plots provided in Annex 3. Note, one negative point estimate for AstraZeneca-Vaxzevria VE against Delta symptomatic disease (reference 112) with 95% CIs crossing 0 is not fully visible in the plot.

Figures 6 and 7 summarize the impact of Omicron and Delta variants, respectively, on product-specific vaccine effectiveness (VE) over time for both primary series vaccines and booster vaccines. The methods for including estimates in the plot are described below. Additional information on vaccine performance against VOCs can also be found in Annex 4.

Interpretation of the results of the VE for the Omicron variant

Limited data are available for the VE for the Omicron variant. However, available estimates show reduced protection of the primary series COVID-19 vaccines against the Omicron variant for all outcomes (*severe disease*, *symptomatic disease*, and *infection*) than has been observed previously for other variants of concern. Importantly, VE estimates against the Omicron variant remains highest for *severe disease*, while they are lower for *symptomatic disease and infection*. Booster vaccination substantially improves VE for all outcomes for all products with available data. More data are needed on the duration of the VE following a booster dose.

VE estimates for the Pfizer BioNTech-Comirnaty vaccine against *severe disease* due to the Omicron variant within the first three months following the primary series (without a booster dose) range from 70-74% and decrease over time since vaccination, with VE estimates of 60% between three and six months, and 35-68% at six months or more. Between three and six months and six months and over, VE estimates for the AstraZeneca-Vaxzevria vaccine against *severe disease* reduced from 56% to 33%, with relatively wide confidence intervals (see Figure 5 for details).

Early VE estimates (measured from 14 days up to three months after vaccination) of the primary series against *symptomatic disease* are generally lower than those for *severe disease*, though it remains at or above 50% for AstraZeneca-Vaxzevria, Moderna-Spikevax, and Pfizer BioNTech-Comirnaty vaccines. In contrast, most estimates of VE against *infection* at 14 days up to three months after the primary series are below 50%. All available estimates against both *symptomatic disease* and *infection* measured three or more months after completion of the primary series indicate VE estimates of less than 50% for the three vaccines (Pfizer BioNTech-Comirnaty, Moderna-Spikevax and AstraZeneca-Vaxzevria).

A booster dose increases VE estimates against *severe disease* to above 75% for all vaccines for which data are available, with this effect maintained up to six months after the booster dose. A booster dose increased VE estimates against *symptomatic disease* in the first three months following vaccination to 63%-78% for all vaccines, however, these decreased to 29-64% at 3-6 months. Limited evidence is available for VE against *infection* due to the Omicron variant following a booster dose, with only one study showing a VE of 68% within the first 3 months of a booster dose of Moderna-Spikevax.

Interpretation of the results of the VE for the Delta variant

Most of the evidence to date supports effectiveness of the mRNA vaccines (Pfizer BioNTech-Comirnaty and Moderna-Spikevax) remains high against *severe disease* associated with Delta variant infection at six or more months after the primary series, with three of four studies reporting VE estimates of >90% and one study reporting a VE of 74% at six months or more. Three studies report high VE (>80%) of the AstraZeneca-Vaxzevria vaccine three to six months following the primary series, while one study reports a lower VE (54%), compared to the first three months (84%).

VE estimates against *symptomatic disease* and *infection* range from 73-96% following the primary series of one of the two mRNA vaccine from 14 days up to three months after vaccination and 68-88% following the primary series of the AstraZeneca-Vaxzevria vaccine during the same time period. There is, however, consistent evidence of decreasing VE against *symptomatic disease* and *infection* over time following the primary series for all of the vaccines for which data are available. Despite this, most of the evidence still report VE estimates of >50% (59-80%) at six months or more following either mRNA vaccine, with two estimates falling below 50%. Three of the four studies of evaluating the AstraZeneca-Vaxzevria vaccine also showed a VE >50% (54-65%) at three to six months, though in one of these studies the VE decreased

to 43%. A single study of Sinovac-CoronaVac (an inactivated vaccine) conducted in Malaysia reported a VE against *infection* of 74% three to six months following the primary series, which decreased to 30% beyond six months.

Receipt of a booster dose of mRNA, vector-based and inactivated vaccines, for which there is data available, resulted in a VE of >79% for *all outcomes* within the first three months. At three to six months following the booster dose, the VE of an mRNA booster vaccine against *severe disease* remained >95% in a single study conducted in the United Kingdom, but decreased to 65% from 95% in a single study conducted in the United States of America in the same time period. The VE against *symptomatic disease* at three months or more following a booster dose with an mRNA vaccine was >75% after a primary series of either the AstraZeneca-Vaxzevria or the Pfizer BioNTech-Comirnaty vaccines.

WHO regional overviews

Epidemiological week 31 January – 6 February 2022**

African Region

The African Region reported over 98 000 new cases, a 22% decrease as compared to the previous week. This follows the declining trend observed since early January 2022. Despite this, two countries still reported increases in new cases of over 20%; Comoros (101 vs 34 new cases, a 197% increase) and Guinea (250 vs 155 new cases; a 61% increase). The highest numbers of new cases were reported from Réunion (45 474 new cases; 5079.1 new cases per 100 000 population; similar to the previous week's figures), South Africa (20 580 new cases; 34.7 new cases per 100 000; a 7% decrease) and Algeria (8288 new cases; 18.9 new cases per 100 000; a 44% decrease).

This week, over 1400 new deaths were reported in the Region, corresponding to a 14% decrease as compared to the previous week. The highest numbers of new deaths were reported from South Africa (912 new deaths; 1.5 new deaths per 100 000 population; an 8% increase), Algeria (85 new deaths; <1 new death per 100 000; a 15% increase) and Uganda (34 new deaths; <1 new death per 100 000; a 31% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 4.4 million new cases, a 36% decrease as compared to the previous week, a trend that has continued since mid-January. However, eight countries reported increases in new cases of 20% or greater, with the highest proportional increases reported from the Dominica (968 vs 515 new cases; an 88% increase) and Honduras (5674 vs 3438 new cases; a 65% increase). The highest numbers of new cases were reported from the United States of America (1 874 006 new cases; 566.2 new cases per 100 000; a 50% decrease), Brazil (1 241 025 new cases; 583.8 new cases per 100 000; similar to the previous week's figures) and Argentina (283 743 new cases; 627.8 new cases per 100 000; a 51% decrease).

This week the number of new deaths remained similar to that of last week with over 29 000 new deaths reported in the Region. The highest numbers of new deaths were reported from the United States of America (14 090 new deaths; 4.3 new deaths per 100 000; a 15% decrease), Brazil (4610 new deaths; 2.2 new deaths per 100 000; a 39% increase) and Mexico (2910 new deaths; 2.3 new deaths per 100 000; a 48% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The number of new weekly cases has continued to increase in the Eastern Mediterranean Region this week, with over 808 000 new cases reported, a 36% increase as compared to the previous week. Increasing numbers of new cases have been reported in the Region since the end of December 2021. This week, nine countries reported increases of 20% or greater, with the highest relative increases reported from the Islamic Republic of Iran, Afghanistan (4046 vs 2118 new cases; a 91% increase) and Jordan. The highest numbers of new cases were reported from the Islamic Republic of Iran (221 654 new cases; 263.9 new cases per 100 000; a 188% increase), Jordan (116 993 new cases; 1146.6 new cases per 100 000; an 85% increase) and the occupied Palestinian territory (58 046 new cases; 1137.8 new cases per 100 000; a 75% increase).

Over 2300 new deaths were reported in the Region this week, corresponding to a 45% increase as compared to the previous week. The highest numbers of new deaths were reported from Tunisia (383 new deaths; 3.2 new deaths per 100 000; a 39% increase), the Islamic Republic of Iran (365 new deaths; <1 new death per 100 000; a 105% increase) and Egypt (311 new deaths; <1 new death per 100 000; a 32% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

Following an increase in the incidence of weekly cases since mid-December 2021, the European Region reported over 11.1 million new cases this week, a 7% decrease as compared to the previous week. However, eleven countries reported an increase in new cases of 20% or greater in the past week. Those reporting the highest relative increase were Belarus (30 475 vs 13 698 new cases; a 122% increase), Azerbaijan (39 839 vs 19 307 new cases; a 106% increase) and the Russian Federation. The highest numbers of new cases were reported from France (1 738 189 new cases; 2672.5 new cases per 100 000; a 26% decrease), Germany (1 285 375 new cases; 1545.5 new cases per 100 000; a 22% increase), and the Russian Federation (1 073 111 new cases; 735.3 new cases per 100 000; a 71% increase).

Over 23 000 new deaths were reported, in the Region, similar to the previous week's number. The highest numbers of new deaths were reported from the Russian Federation (4686 new deaths; 3.2 new deaths per 100 000; similar to the previous week), Italy (2628 new deaths; 4.4 new deaths per 100 000; similar to the previous week), and France (1867 new deaths; 2.9 new deaths per 100 000; similar to the previous week's figures).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported a marked decline of 32% in new cases in the past week, with over 1.4 million new cases reported. However, half of the countries in the Region (5/10) still reported increases in new cases of 20% or greater, with the countries reporting the highest proportional increase including: Timor-Leste (466 vs 69 new cases; a 575% increase), Indonesia and Myanmar (2647 vs 1183 new cases; a 124% increase). The highest numbers of new cases were reported from India (1 095 616 new cases; 79.4 new cases per 100 000; a 41% decrease), Indonesia (173 295 new cases; 63.4 new cases per 100 000; a 205% increase), and Bangladesh (76 200 new cases; 46.3 new cases per 100 000; a 24% decrease).

Conversely, the Region reported a 67% increase in the number of newly reported deaths as compared to the previous week, with over 8700 new deaths reported. This is largely due to reporting of back-dated deaths in India. The highest numbers of new deaths were reported from India (7888 new deaths; <1 new death per 100 000; a 68% increase), Indonesia (251 new deaths; <1 new death per 100 000; a 202% increase), and Bangladesh (226 new deaths; <1 new death per 100 000; a 61% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Following an increase in the number new cases last week, the Western Pacific Region reported over 1.3 million new cases, an 8% decrease as compared to the previous week. However, nearly half (13/28; 46%) of the countries in the Region reported increases in new cases of 20% or greater with the highest increases reported from Kiribati (1206 vs 142 new cases; a 749% increase), Brunei Darussalam (1059 vs 261 new cases; a 306% increase) and the Solomon Islands (1892 vs 609 new cases; a 211% increase). The highest numbers of new cases were reported from Japan (623 128 new cases; 492.7 new cases per 100 000; a 34% increase), Australia (215 234 new cases; 844.1 new cases per 100 000; a 57% decrease), and the Republic of Korea (181 053 new cases; 353.1 new cases per 100 000; a 91% increase).

The number of new deaths also declined in the Region with over 2400 new deaths reported, a 5% decrease as compared to the previous week. The highest numbers of new deaths were reported from Viet Nam (714 new deaths; <1 new death per 100 000; a 25% decrease), Australia (528 new deaths; 2.1 new deaths per 100 000; a 7% decrease), and Japan (528 new deaths; <1 new death per 100 000; a 121% increase).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 8 February, highlights include the following:

- Donating SD Biosensor Test Kits to support Belize's COVID-19 response
- Enhancing risk communication and community engagement activities in Thailand
- Italy joins other European Union Member States to increase pledge of COVID-19 vaccines to Syria
- Integration and expansion: Leveraging influenza systems for the COVID-19 response
- Launching the SocialNet online course on OpenWHO
- Updates on WHO's financing to support countries on COVID-19 response implementation to suppress transmission, reduce exposure, and protect the vulnerable and save lives
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

*

unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Annex 3. Methods for Figures 6 and 7

- Figures include five studies from Denmark, South Africa, the United Kingdom, and the United States of America evaluating the VE against the Omicron variant, and 19 studies of the VE against the Delta variant from various countries from the European Region and Region of the Americas, as well as Qatar, Malaysia and Singapore.
- VE studies included in the plot were identified from an ongoing systematic review of COVID-19 vaccine effectiveness studies. All studies were cohort or test-negative studies. Methods for the systematic review and inclusion/exclusion criteria are available on view-hub.org. The studies were conducted during a period when either Delta or Omicron was the predominant circulating variant. Estimates were included if they were of laboratory-confirmed cases of the Omicron or Delta variant. In addition, for the primary series VE, only studies providing VE estimates for discrete time intervals since vaccination, which evaluate changes in VE over time, are included.
- For the primary series VE, estimates are only included in the plot for studies that report VE for more than one time period.

- When the time interval post vaccination spanned two intervals in the plot, the estimate was placed in the time period (panel in the plot) based on the median time point of the interval.
- Estimates are not plotted if different vaccine products are combined to produce the VE estimate. Heterologous schedules are included if all individuals in the study received the vaccine products in the same order (for example, VE estimates of AstraZeneca-Vaxzevria primary series followed by Pfizer BioNTech-Comirnaty booster are included; VE estimates of AstraZeneca-Vaxzevria primary series followed by any mRNA booster are excluded).

Annex 4. Summary of primary series vaccine performance against Variants of Concern (data as of 4 February 2022)

	WHO Emergency Use Listing (EUL) Qualified Vaccines ⁺								Vaccines without WHO EUL ⁺	
	AstraZeneca-Vaxzevria/SII - Covishield	Beijing CNBG-BBIBP-CorV	Bharat-Covaxin	Janssen-Ad26.COV 2.S	Moderna-mRNA-1273	Novavax-Covavax	Pfizer BioNTech-Comirnaty	Sinovac-Corona Vac	Anhui ZL-Recombinant	Gamaleya-Sputnik V
Alpha, Beta, Gamma										
Summary of VE*	(see update from 11 January 2022 for details of vaccine performance against Alpha, Beta, and Gamma variants of concern)									
Delta										
Summary of VE*	Protection retained against severe disease; possible reduced protection against symptomatic disease and infection									
- Severe disease+	↔ ₃	-	-	↓ ₁	↔ ₄	-	↔ ₇	-	-	-
- Symptomatic disease	↔ _{to} ↓↓ ₆	-	↓ ₁	-	↔ ₂	-	↔ _{to} ↓ ₅	-	-	-
- Infection	↔ _{to} ↓ ₅	-	-	↓↓↓ ₁	↔ ₆	-	↔ _{to} ↓ ₆	-	-	-
Neutralization	↓ ₁₃	↓ ₂	↔ _{to} ↓ ₄	↔ _{to} ↓↓↓ ₁₀	↓ ₁₃	-	↔ _{to} ↓ ₃₉	↓ _{to} ↓↓↓ ₉	↔ _{to} ↓ ₂	↓ _{to} ↓↓↓ ₃
Omicron										
Summary of VE*	Reduced protection against infection and symptomatic disease; possible reduced protection against severe disease but limited evidence									
- Severe disease+	-	-	-	-	-	-	↓↓↓/ ↓↓↓ ₂	-	-	-
- Symptomatic disease	↓↓↓ ₁	-	-	-	↓↓↓ ₁	-	↓↓↓ ₁	-	-	-
- Infection	↓↓↓ ₁	-	-	-	↓↓↓ ₃	-	↓↓↓ ₃	-	-	-
Neutralization	↓↓↓ ₆	↔ _{to} ↓↓↓ ₃	↓ ₁	↓ ₂	↓↓↓ ₁₅	-	↓↓↓ ₃ 2	↓↓↓ _{to} ↓↓↓ ₄	-	↓ ₁

refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10 percentage point (pp) reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20 pp reduction in VE, or 2 to <5-fold reduction in neutralization; “↓_↓” 20 to <30 pp reduction in VE, or 5 to <10-fold reduction in neutralization; “↓_↓ ↓_↓” ≥30 pp reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table. + Severe disease is defined differently across studies and may include outcomes such as hospitalization, critical disease, and other forms of ‘severe’ disease.

Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean a loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the Table 3.

COVID-19 Weekly Epidemiological Update

Edition 77, published 01 February 2022

In this edition:

- [Global overview](#)
- [Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 30 January 2022

Globally, during the week of 24 to 30 January 2022, the number of new COVID-19 cases remained similar to the number reported during the previous week, while the number of new deaths increased by 9% (figure 1). Across the six WHO regions, over 22 million new cases and over 59 000 new deaths were reported (table 1). As of 30 January 2022, over 370 million confirmed cases and over 5.6 million deaths have been reported globally.

At the Regional level, increases in the number of new cases were reported by the Western Pacific (37%) the Eastern Mediterranean (24%) and the European (7%) Regions, while decreases were reported by the Region of the Americas (20%) and the South-East Asia Region (8%). The number of new cases reported in the African Region remained similar to that of the previous week. The number of new weekly deaths continued to increase in the South-East Asia Region (41%), the Eastern Mediterranean Region (32%) and the Region of the Americas (16%), while the African Region reported a decrease of 7%. The incidence of deaths remained similar to the previous week in the European and the Western Pacific regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 30 January 2022**

**See [Annex 2: Data, table, and figure notes](#)

At the country level, the highest numbers of new cases were reported from the United States of America (3 279 226 new cases; a 34% decrease), France (2 357 129 new cases; similar to the previous week's figures), India (1 855 258 new cases; a 12% decrease), Brazil (1 283 024 new cases; a 56% increase), and Germany (1 055 768 new cases; a 48% increase). The highest number of new deaths were reported from the United States of America (13 558 new deaths; a 5% decrease), India (4682 new deaths; a 40% increase), the Russian Federation (4616 new deaths; similar to the previous week), Brazil (3321 new deaths; an 88% increase) and Italy (2618 new deaths; a 7% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 30 January 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	11 425 243 (51%)	7%	142 000 542 (38%)	21 586 (36%)	-2%	1 763 374 (31%)
Americas	6 548 409 (29%)	-20%	134 200 558 (36%)	26 553 (45%)	16%	2 497 750 (44%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the continued rapid global spread of the Omicron variant. All other variants, including VOCs (Alpha, Beta, Gamma and Delta) and VOIs (Lambda and Mu) continue to decline in all six WHO regions. Among the 433 223 sequences uploaded to [GISAID](#) with specimens collected in the last 30 daysⁱ, 403 991 (93.3%) were Omicron, 29 004 (6.7%) were Delta, four (<0.1%) were Gamma, three (<0.1%) were Alpha, one (<0.1%) was Beta and two (<0.1%) comprised other circulating variants (VOIs Mu and Lambda). To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

The Omicron variant

Since the designation of B.1.1.529 as a VOC on 26 November 2021, several Omicron lineages have been identified. These include Pango lineages BA.1, BA.1.1, BA.2 and BA.3, which are all being monitored by WHO under the umbrella of 'Omicron'. The common origin of these lineages has not yet been elucidated and it is not clear to date how and where the Omicron parental variant or the descendent lineages originated and further evolved.

The Omicron variant-defining constellation of mutations fully overlaps with Pango lineage BA.1 (including lineage BA.1.1), and this accounts for 96.4% of sequences submitted to GISAID as of 31 January 2022. Most evidence we have to date about Omicron is therefore based on this Pango lineage. A relative increase in the BA.2 variant, which differs from BA.1 in some of the mutations, including in the spike protein, has been observed in multiple countries. BA.2-designated sequences have been submitted to GISAID from 57 countries to date, with the weekly proportion of BA.2 relative to other Omicron sequences rising to over 50% during the last six weeks in several countries. Investigations into the characteristics of BA.2, including transmissibility, immune escape properties and virulence, should be prioritized independently (and comparatively) to BA.1 ([WHO Tracking SARS-CoV-2 variants website](#)). It is important to consider the relative proportions of BA.1 and BA.2 sequences in the context of the case incidence when interpreting the data.

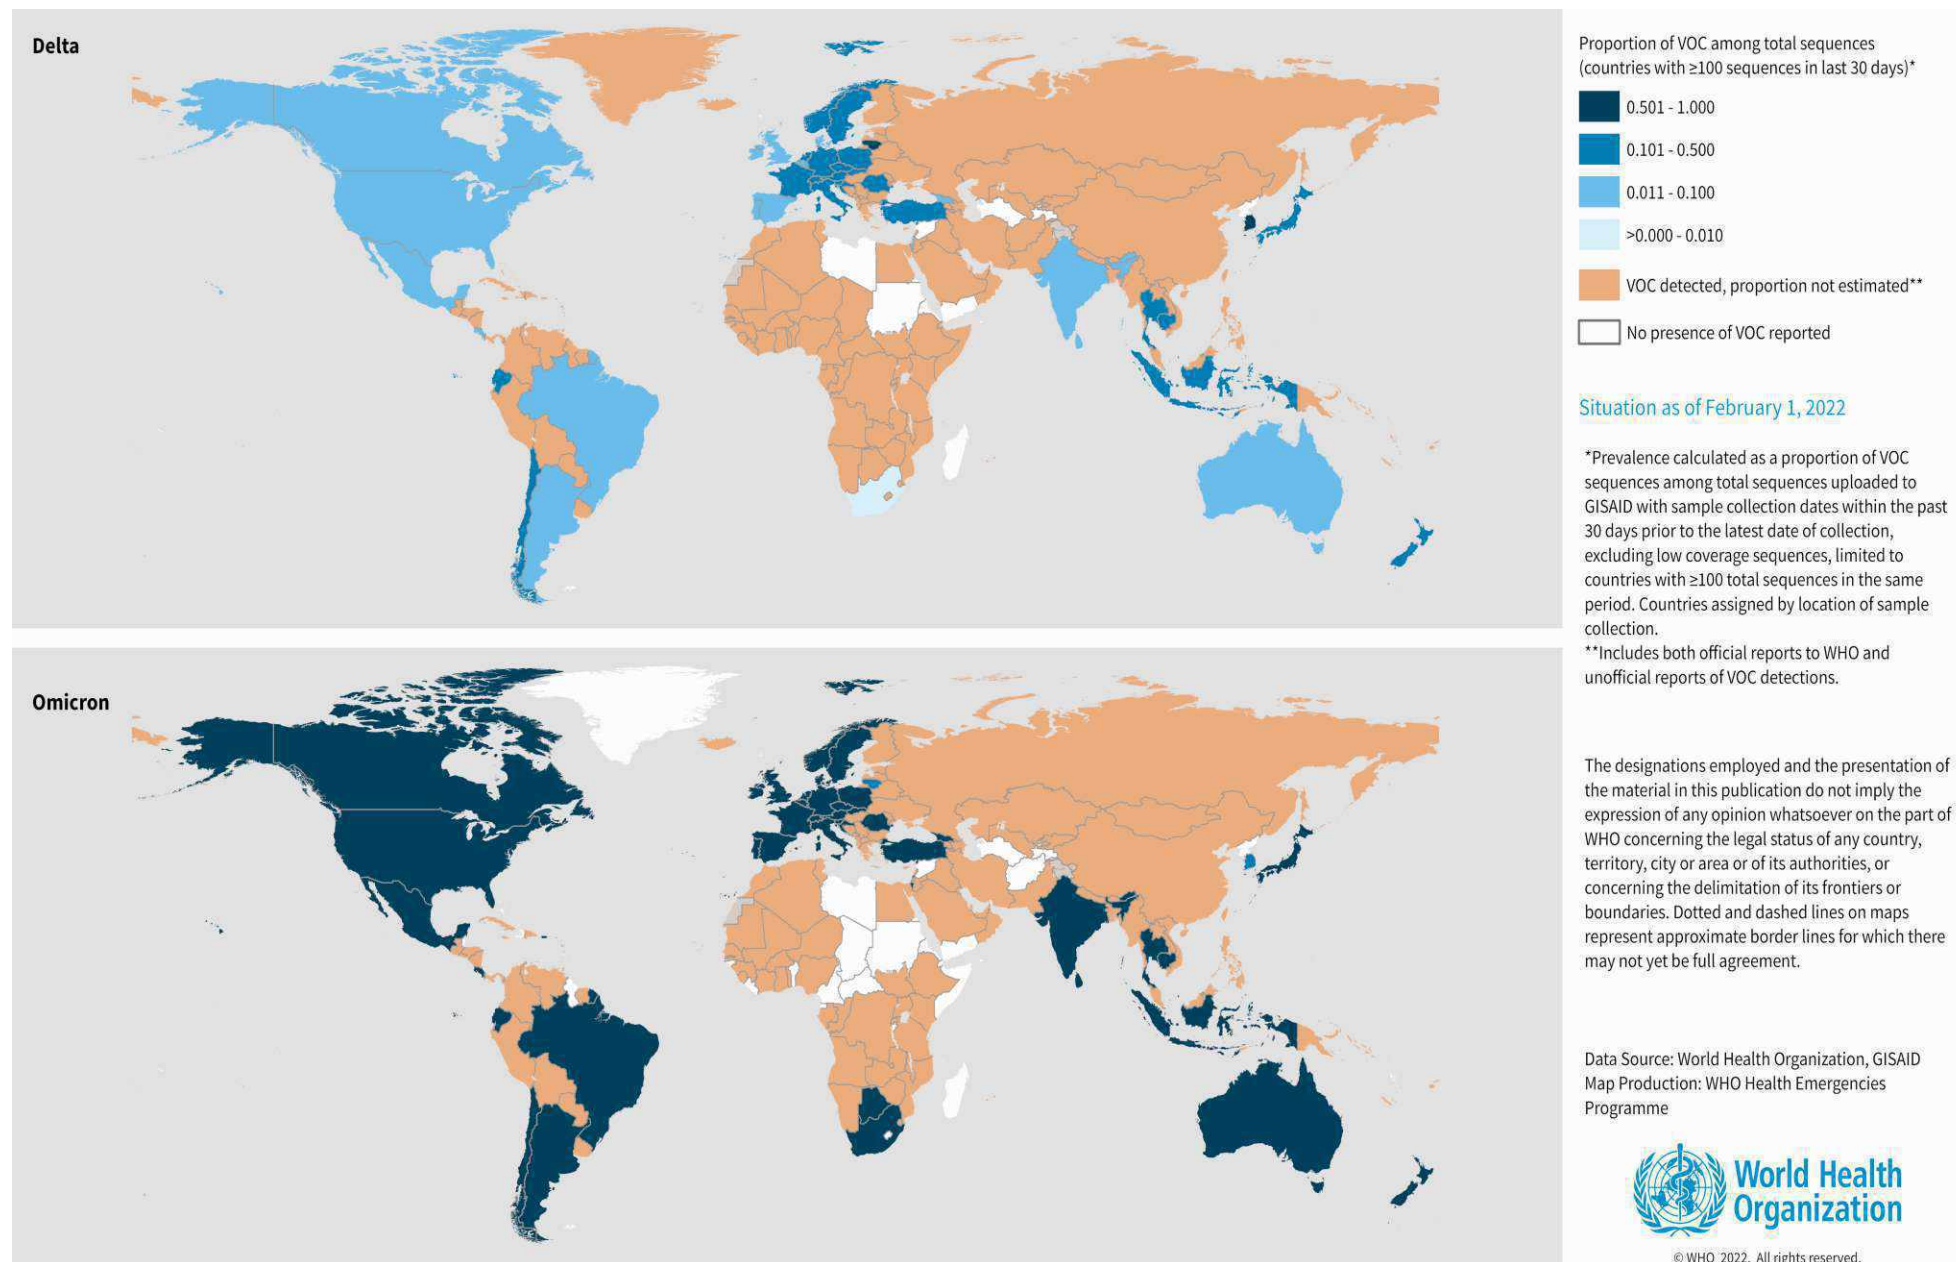

WHO continues to monitor circulating and emerging variants and to identify and address relevant knowledge gaps through the development of coordinated, multi-layered surveillance, preparedness, and response strategies for addressing COVID-19.

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 31 December 2021 to 29 January 2022 (last reported sample at the time of data extraction), excluding low coverage sequences)

See also [Annex 2](#) for reported VOC detections by country/territory/area

African Region

The African Region reported over 125 000 new cases, similar to the number reported during the previous week. This follows on from a decreasing trend in new cases that has been observed for over a month. However, six countries (12%) reported increases of 20% or greater, with the highest increases reported from the Central African Republic (410 vs 190 new cases, a 116% increase), Lesotho (277 vs 165 new cases, a 68% increase) and Algeria. The highest numbers of new cases continued to be reported from Réunion (46 914 new cases; 5240.0 new cases per 100 000 population; a 49% increase), South Africa (22 202 new cases; 37.4 new cases per 100 000; similar to the previous week's figures), and Algeria (14 774 new cases; 33.7 new cases per 100 000; a 63% increase).

The number of new weekly deaths continued to decline in the Region with over 1600 new deaths reported, a 7% decrease as compared to the previous week. The highest numbers of new deaths were reported from South Africa (842 new deaths; 1.4 new deaths per 100 000 population; a 7% increase), Ethiopia (91 new deaths; <1 new death per 100 000; a 13% decrease), and Algeria (74 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [African Region](#)

Region of the Americas

Since mid-January 2022, the Region of the Americas has continued to report a decrease in the number of new cases, with over 6.5 million cases reported this week, a 20% decrease as compared to the previous week. Only four countries reported increases of 20% or greater including: the Falkland Islands (3 vs 1 new case, a 200% increase), Chile (157 937 vs 82 574 new cases, a 91% increase), El Salvador (6250 vs 3435 new cases, an 82% increase) and Brazil. The highest numbers of new cases were reported from the United States of America (3 279 226 new cases; 990.7 new cases per 100 000; a 34% decrease), Brazil (1 283 024 new cases; 603.6 new cases per 100 000; a 56% increase), and Argentina (619 108 new cases; 1369.8 new cases per 100 000; a 19% decrease).

Over 26 000 new weekly deaths were reported in the Region, corresponding to a 16% increase as compared to the previous week. The highest numbers of new deaths continued to be reported from the United States of America (13 558 new deaths; 4.1 new deaths per 100 000; a 5% decrease), Brazil (3321 new deaths; 1.6 new deaths per 100 000; an 88% increase), and Mexico (2066 new deaths; 1.6 new deaths per 100 000; a 67% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

Since the end of December 2021, the Eastern Mediterranean Region reported a continued increase in new cases. During the last week, over 596 000 new cases were reported, a 24% increase as compared to the previous week. Over half of the countries (13/22, 59%) reported increases of 20% or greater, with the highest increases reported from the occupied Palestinian territory (33 080 vs 7293 new cases; 354% increase), the Islamic Republic of Iran and Libya (16 399 vs 6692 new cases; a 145% increase). The highest numbers of new cases were reported from the Islamic Republic of Iran (76 837 new cases; 91.5 new cases per 100 000; a 189% increase), Jordan (63 153 new cases; 619.0 new cases per 100 000; a 72% increase), and Tunisia (54 346 new cases; 459.8 new cases per 100 000; an 18% decrease).

Over 1600 new weekly deaths were reported in the Region, a 32% increase as compared to the previous week. The highest numbers of new deaths were reported from Tunisia (275 new deaths; 2.3 new deaths per 100 000; a 55% increase), Egypt (236 new deaths; <1 new death per 100 000; a 14% increase) and Morocco (215 new deaths; <1 new death per 100 000; a 43% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

Since mid-December 2021, the number of new cases has continued to rise, with the Region reporting over 11.4 million new cases this week, a 7% increase as compared to the previous week. Twenty-three countries (38%) reported an increase greater than 20%, with the highest increases reported from Armenia (14 722 vs 4094 new cases; a 260% increase), Azerbaijan (19 307 vs 7116 new cases; a 171% increase), and Tajikistan (143 vs 59 new cases; a 142% increase). The highest numbers of new cases were reported from France (2 357 129 new cases; 3624.2 new cases per 100 000; similar to the previous week's figures), Germany (1 055 768 new cases; 1269.5 new cases per 100 000; a 48% increase), and Italy (1 040 184 new cases; 1744.1 new cases per 100 000; a 16% decrease).

The number of weekly deaths in the Region remained similar to that of the previous week with over 21 000 reported. The highest numbers of new deaths were reported from the Russian Federation (4616 new deaths; 3.2 new deaths per 100 000; similar to the previous week's figures), Italy (2618 new deaths; 4.4 new deaths per 100 000; a 7% increase), and France (1881 new deaths; 2.9 new deaths per 100 000; a 19% increase).

Updates from the [European Region](#)

South-East Asia Region

Following an increase in the number of new cases over the past month, the number of new cases in the South-East Asia Region decreased, with over 2.1 million new cases reported this week, an 8% decrease as compared to the previous week. However, seven out of ten countries in the region reported an increase greater than 20% in the number of new weekly cases, with the largest increases reported from Timor-Leste (69 vs 5 new cases; a 1280% increase), Indonesia and Bangladesh. The highest numbers of new cases were reported from India (1 855 258 new cases; 134.4 new cases per 100 000; a 12% decrease), Bangladesh (100 196 new cases; 60.8 new cases per 100 000; a 49% increase), and Indonesia (56 807 new cases; 20.8 new cases per 100 000; a 286% increase).

The number of new deaths in the Region increased by 41% as compared to the previous week, with over 5200 new deaths reported. The highest numbers of new deaths were reported from India (4682 new deaths; <1 new death per 100 000; a 40% increase), Bangladesh (140 new deaths; <1 new death per 100 000; a 77% increase), and Thailand (125 new deaths; <1 new death per 100 000; a 17% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The number of new cases in Western Pacific Region increased by 37% as compared to the previous week, with over 1.4 million new cases reported. Half of the countries in the Region (n=14) reported increases of over 20% in new cases, with the highest proportional increases reported from Papua New Guinea (339 vs 81 new cases; a 319% increase), Kiribati (142 vs 39 new cases; a 264% increase) and Palau (1021 vs 319, a 220% increase). The highest numbers of new cases continued to be reported from Australia (499 935 new cases; 1960.5 new cases per 100 000; a 65% increase), Japan (463 354 new cases; 366.4 new cases per 100 000; a 73% increase), and the Philippines (141 339 new cases; 129.0 new cases per 100 000; a 36% decrease).

The number of new weekly deaths in the Region remained similar to that of the previous week, with over 2500 new deaths reported. The highest numbers of new deaths were reported from Viet Nam (951 new deaths; 1.0 new death per 100 000; an 15% decrease), Australia (565 new deaths; 2.2 new deaths per 100 000; a 31% increase) and the Philippines (465 new deaths; <1 new death per 100 000; a 15% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 1 February, highlights include the following:

- Receiving 230 Oxygen Cylinders in Suriname, donated by Germany and the Region of the Americas
- Holding the first mentors training in the World Health Emergencies Balkan Hub, marking one year of COVID-19 vaccination in India
- Setting up country support teams to scale up COVID-19 vaccination in the WHO African Region
- Supporting Iraq with over 20 tons of medical supplies to enhance national response to COVID-19 health challenges in the Kurdistan region
- Receiving COVID-19 vaccines in the Lao People's Democratic Republic, donated by the United States of America through the COVAX Facility
- Strengthening occupational health and safety in Japan during the pandemic
- Hosting the first Regional team member training at the Emergency Medical Teams (EMT) Training Centre for Africa
- Updates on WHO's financing to support countries on COVID-19 response implementation to suppress transmission, reduce exposure, and protect the vulnerable and save lives
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

**Newly reported*

*unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)*

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 76, published 25 January 2022

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 23 January 2022

Globally, the number of new COVID-19 cases increased by 5% in the past week (17-23 January 2022), while the number of new deaths remained similar to that reported during the previous week (Figure 1). Across the six WHO regions, over 21 million new cases were reported, representing the highest number of weekly cases recorded since the beginning of the pandemic. Nearly 50 000 new deaths were also reported. As of 23 January 2022, over 346 million confirmed cases and over 5.5 million deaths have been reported in total.

A slower increase in case incidence was observed at the global level, with only half of the regions reported an increase in the number of new weekly cases, as compared to five out of six regions in the previous week. The Eastern Mediterranean Region reported the largest increase in the number of new cases (39%), followed by the South-East Asia Region (36%) and the European Region (13%). The African Region reported the largest decrease in the number of new cases (31%), followed by the Region of the Americas (10%), while the number of new cases in the Western Pacific Region remained similar to that reported during the previous week. The number of new weekly deaths increased in the South-East Asia Region (44%), the Eastern Mediterranean Region (15%) and the Region of the Americas (7%), while the other Regions all reported declines in new weekly deaths.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 23 January 2022**

**See [Annex 2: Data, table, and figure notes](#)

At the country level, the highest numbers of new cases were reported from the United States of America (4 215 852 new cases; a 24% decrease), France (2 443 821 new cases; a 21% increase), India (2 115 100 new cases; a 33% increase), Italy (1 231 741 new cases; similar to the previous week), and Brazil (824 579 new cases; a 73% increase). The highest number of new deaths were reported from the United States of America (10 795 new deaths; a 17% decrease), the Russian Federation (4792 new deaths; a 7% decrease), India (3343 new deaths; a 47% increase), Italy (2440 new deaths; a 24% increase), and The United Kingdom (1888 new deaths; similar to the previous week's figures).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 23 January 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	10 040 147 (47%)	13%	129 874 912 (37%)	21 259 (43%)	-5%	1 740 565 (31%)
Americas	7 356 674 (34%)	-10%	126 761 620 (37%)	19 357 (39%)	7%	2 466 600 (44%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the dominance of the Omicron variant on a global scale, continued decline in the prevalence of the Delta variant, and very low-level circulation of Alpha, Beta and Gamma variants. The Omicron variant includes Pango lineages B.1.1.529, BA.1, BA.2 and BA.3. BA.1 accounts for 98.8% of sequences submitted to GISAID as of 25 January 2022, although a number of countries have reported recent increases in the proportion of BA.2 sequences. All these variants are being monitored by WHO under the umbrella of 'Omicron'. Following the identification of travel-related cases of the Omicron variant, many countries are now reporting community transmission. Countries that experienced a rapid rise in Omicron cases in November and December 2021 have been or are beginning to see declines in cases.

Among the 372 680 sequences uploaded to GISAID with specimens collected in the last 30 daysⁱ, 332 155 (89.1%) were Omicron, 39 804 (10.7%) were Delta, 28 (<0.1%) were Gamma, four (<0.1%) were Alpha and two (<0.1%) comprised other circulating variants (VOIs Mu and Lambda). To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Differences in the characteristics of VOCs

Available evidence on the phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last update on 11 January 2022](#), there are several new publications on the phenotypic characteristics of VOCs, including recent literature on Omicron. Some of the studies reported have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Update on the Omicron VOC

This section provides a summary of the potential impact of the Omicron variant. Detailed information on this variant and related recommended priority actions for Member States can be found in the [updated Technical Brief and Priority Actions](#) for Member States that was published by WHO on 21 January 2022. Based on the currently available evidence, the overall risk related to the Omicron variant remains very high. Compared to other variants, Omicron has shown an increased ability to spread within the community, leading to a rapid increase in the numbers of new cases in multiple countries where it has replaced other variants, including Delta. Despite this, there appears to be a lower risk of severe disease and death following Omicron infection as compared to other variants. However, due to

ⁱ This includes sequences submitted to [GISAID](#) with sample collected dates from 25 December 2021 to 23 January 2022 (last reported sample at the time of data extraction), excluding low coverage sequences.

the very high numbers of cases, many countries have seen a significant increase in the incidence of hospitalization, putting pressure on healthcare systems.

Transmissibility

The Omicron variant has a significant growth advantage, a higher secondary attack rate and a higher observed reproduction number as compared to the Delta variant, and as a result, it is rapidly replacing the latter globally. It is thought that this transmission advantage is largely due to Omicron's ability to evade immunity following infection and/or vaccination. However, compared to the Delta variant, Omicron is able to more rapidly infect the tissues of upper respiratory tract rather than the lungs, which may also help the spread of this variant. Studies conducted in the United Kingdom and Denmark showed that household contacts of cases with the Omicron variant were more likely to be infected as compared to those who were contacts of cases with the Delta variant: the household secondary attack rate in the study conducted in the United Kingdom was 13.6% for the Omicron as compared to 10.1% for the Delta variant; and for the study conducted in Denmark, 31% for the Omicron as compared to 21% for the Delta variant.¹ Additionally, studies conducted in India and South Africa have reported a higher proportion of asymptomatic infection at the time of testing among individuals infected with Omicron compared to infection with Delta. The higher occurrence of asymptomatic presentation may result in a lower rate of detection, and thus may further contribute to transmission.²

Disease severity

Epidemiological trends continue to show a decoupling between case incidence, hospital admissions and deaths in most countries, when compared to epidemic waves due to previous variants. This is likely due to a combination of the lower intrinsic severity of the Omicron variant (including increased likelihood of replication in the upper respiratory tract rather than the lungs), and preservation of protection against severe disease following vaccination.

Several studies have evaluated the risk of hospitalization and severe disease with Omicron as compared to Delta. An analysis from the United Kingdom Health Security Agency with the Medical Research Council (MRC) Biostatistics Unit, the University of Cambridge, showed a 47% reduction in the risk of presentation to emergency care or hospital admission with Omicron compared to Delta (Hazard Ratio [HR] 0.53, 95%CI 0.50-0.57) and 66% reduction in the risk of admission from emergency departments (HR 0.33, 95%CI 0.3-0.37).³ However, uncertainty remains about the severity and the impact on hospitalizations in populations with low vaccination coverage or prior exposure to SARS-CoV-2 infection.

Impact on immunity

The Omicron variant has an increased ability to evade immunity as compared to prior variants, causing re-infections in those who have had a previous infection and in those who have been vaccinated. Here we summarise the risk of re-infection as further details on vaccine effectiveness are given in the section on vaccines below. A study conducted in the United Kingdom found that, when compared to the Delta variant, the risk of reinfection with the Omicron variant was 5.4-fold higher.⁴ In those who were unvaccinated, this risk was slightly higher at 6.4-fold and in those who were vaccinated, slightly lower at 5.0-fold. A separate study conducted in the United Kingdom found that those who had a lower viral load (higher Ct value) during their previous infection were at a higher risk of reinfection.⁵

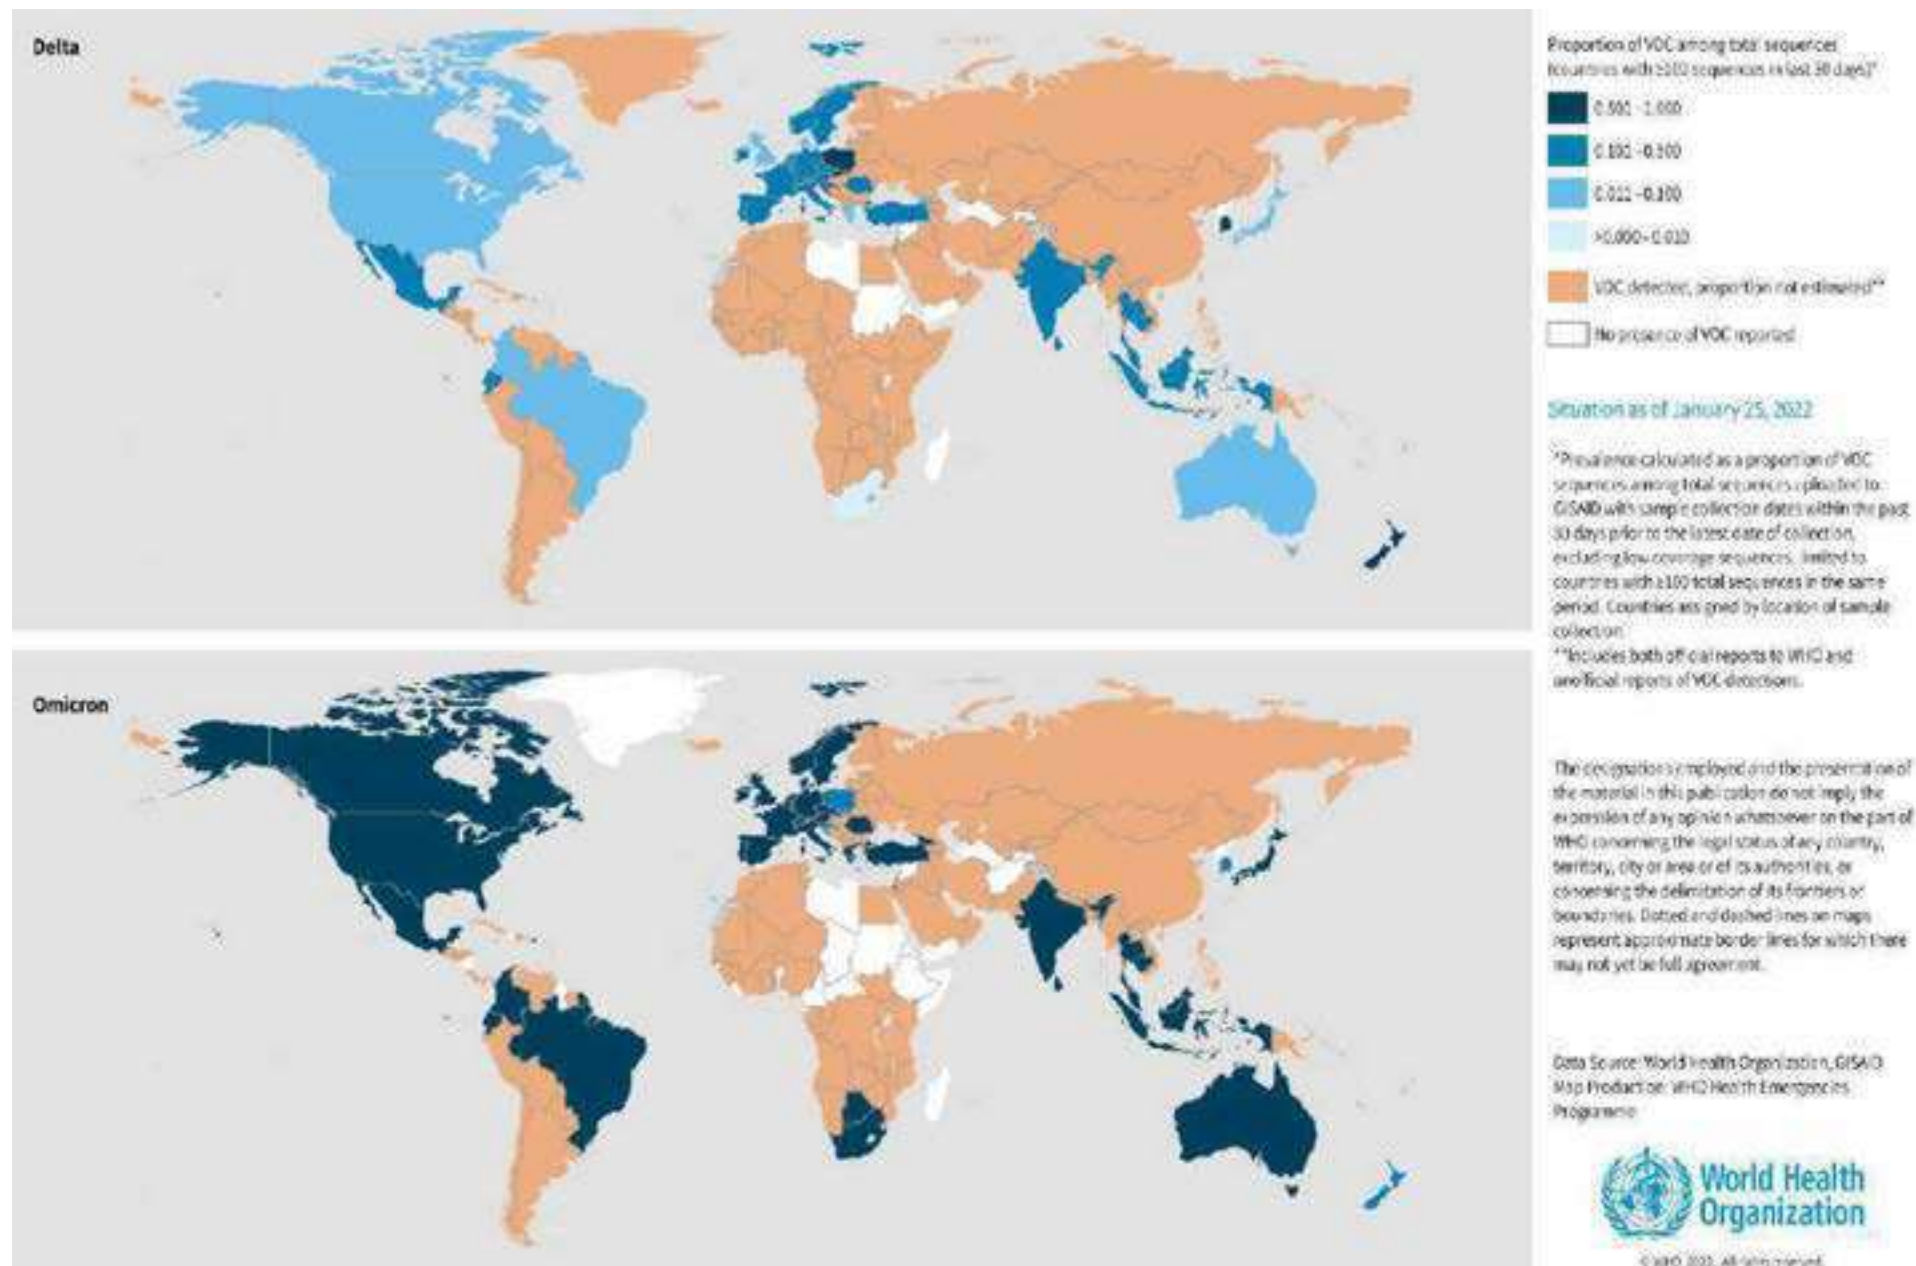

Impact on therapeutics

There is ongoing research to understand the impact of the Omicron variant on therapeutics and treatments. It is expected that corticosteroids and drugs which block the cytokine interleukin 6 (IL-6) will remain effective in those with severe disease. However, preliminary data from non-peer-reviewed publications suggest that some of the monoclonal antibodies may be less effective against the Omicron variant.

Impact on diagnostics and testing

WHO continues to assess the impact of Omicron on diagnostics; however, the diagnostic accuracy of routinely used PCR and the [WHO emergency use listing \(EUL\) approved](#) antigen-detection rapid diagnostic test assays does not appear to be significantly impacted by Omicron.

Figure 4: Prevalence of variants of concern (VOCs) Delta and Omicron in the last 30 days, data as of 25 January 2022

See also [Annex 2](#) for reported VOC detections by country/territory/area

Table 2: Summary of phenotypic impacts* of variants of concern

WHO label	Alpha	Beta	Gamma	Delta	Omicron
Transmissibility	Increased transmissibility ⁶	Increased transmissibility ^{7,8}	Increased transmissibility ^{8,9}	Increased transmissibility ^{8,10,11}	Increased transmissibility. ^{12–15}
Disease severity	Possible increased risk of hospitalization ^{16,17} , possible increased risk of severe disease and death ^{18,19}	Possible increased risk of hospitalization ¹⁷ , possible increased in-hospital mortality ²⁰	Possible increased risk of hospitalization ¹⁷ , possible increased risk of severe disease ²¹	Possible increased risk of hospitalization ^{22,23}	Reduced risk of hospitalization and severe disease ^{24–27}
Risk of reinfection	Neutralizing activity retained ²⁸ , risk of reinfection remains similar ²⁹	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ³⁰	Moderate reduction in neutralizing activity reported ³¹	Reduction in neutralizing activity reported ^{32–34}	Increased risk of reinfection ^{35,36}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ³⁷	No impact on RT-PCR or Ag RDTs observed ³⁴	None reported to date	No impact on RT-PCR or Ag RDTs observed ³⁸	PCR continues to detect Omicron. Impact on Ag-RDTs is under investigation: Results are mixed as to whether or not there may be decreased sensitivity to detect Omicron. ^{12,27,39–41}

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table. + Severe disease is defined differently across studies and may include outcomes such as hospitalization, critical disease, and other forms of ‘severe’ disease.

Table 3 summarizes the impact of the Delta and Omicron variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in the VE in the setting of variants compared to non-VOC settings.

Omicron VOC

Since the [11 January update](#), three new studies have provided additional evidence of reduced vaccine effectiveness of mRNA vaccines against infection and symptomatic disease due to the Omicron variant.¹⁻³ These studies report decreased VE of two doses of mRNA vaccines against infection and symptomatic disease due to the Omicron variant compared to the Delta variant within the first few months of receipt of the second dose, with VE estimates decreasing more rapidly with increasing time from completion of the primary series.

A peer-reviewed study from the United States of America reported VE estimates against symptomatic disease of approximately 40% and 30% for Moderna-mRNA-1273 and Pfizer BioNTech-Comirnaty, respectively, one month following two doses of vaccination. However, by 6-7 months following the second dose, VE had declined to 0% for both vaccines.⁴²

A second study of adults in the United States of America (not yet peer reviewed) provides new evidence of the VE of Pfizer BioNTech-Comirnaty against hospitalization due to the Omicron variant.² The vaccine was 70% effective at preventing hospitalization due to Omicron within the first 3 months of the second dose with no decrease in VE found at 6 months. This same study found a third dose of Pfizer BioNTech-Comirnaty increased VE against hospitalization due to Omicron to 89% (83-92%) which was sustained at 3-5 months. However, a VE against emergency department visits not leading to hospital admission decreased from 78% (95%CI 73-82%) immediately following the third dose to 48% (95%CI 14-69%) at 6 months or more.⁴²

In addition to VE against hospitalization, the three studies also showed that a third dose of mRNA vaccine increased VE from 0% to 62-78% for infection and symptomatic disease in the first 3-5 months following a third dose.

Delta VOC

Five new studies (four pre-prints and one peer-reviewed study) provided further evidence of performance of two doses of vaccine against the Delta variant.⁴³⁻⁴⁷ The VE of the Pfizer BioNTech-Comirnaty vaccine against infection and symptomatic disease within 1-3 months after receipt of the second dose ranged from 80-91% but decreased with increasing time to a VE of 53-79% at four or more months following the second dose. The VE against hospitalization for Pfizer BioNTech-Comirnaty was high (88-95%) after the second dose. However, one study showed a reduction in the VE against hospitalization to 74% (65-80%) at six or more months following the second dose.⁴³

Five new studies (three pre-prints and two peer-reviewed studies) also provide further evidence of the vaccine performance of a third dose against infection, symptomatic disease, and hospitalization when the Delta variant was the predominant circulating variant.^{42-44,48,49} The VE of three doses of mRNA vaccines against infection and symptomatic disease ranged from 77-96% across studies.^{42-44,48,49} Two studies (both not yet peer-reviewed) evaluated VE of three doses of the Pfizer BioNTech-Comirnaty vaccine against hospitalization. The first study reported a relative VE (as compared to those receiving two doses, five or more months prior) of 89% (95%CI 87-91%).⁴⁸ The second study reported an absolute VE (as compared to those unvaccinated) of 95% (95%CI 91-97%) against hospitalization due to the Delta variant within three months of receipt of the third dose; however, VE at approximately 3-5 months decreased to 65% (16-85%).⁴³

African Region

The African Region reported a continued decline in case incidence in the past week with over 131 000 new cases reported, a 31% decrease. However, four countries (4/49; 8%) reported increases of 20% or greater: Algeria, Réunion, Burkina Faso (542 vs 425 new cases; 28% increase) and the United Republic of Tanzania (998 vs 831 new cases; 20% increase). The highest numbers of new cases were reported from Réunion (31 401 new cases; 3507.3 new cases per 100 000 population; a 93% increase), South Africa (22 795 new cases; 38.4 new cases per 100 000; a 35% decrease), and Algeria (9052 new cases; 20.6 new cases per 100 000; a 142% increase).

The number of new deaths also continued to decline in the Region with over 1700 new deaths reported, a 14% decrease compared to the previous week. The highest numbers of new deaths were reported from South Africa (785 new deaths; 1.3 new deaths per 100 000 population; a 13% decrease), Ethiopia (105 new deaths; <1 new death per 100 000; a 5% decrease), and Namibia (98 new deaths; 3.9 new deaths per 100 000; an 8% decrease).

Updates from the [African Region](#)

Region of the Americas

Following four weeks of increases in the number of new cases, the Region of the Americas reported over 7.3 million new cases, a 10% decrease as compared to the previous week. However, nearly one-third of the countries in the Region reported increases of 20% or greater (18/56; 32%), with the highest increases reported from Dominica (754 vs 273 new cases; 176%), El Salvador (3435 vs 1343 new cases; 156%) and Venezuela (Bolivarian Republic of) (13033 vs 6003 new cases; 117%). The highest numbers of new cases were reported from the United States of America (4 215 852 new cases; 1273.7 new cases per 100 000; a 24% decrease), Brazil (824 579 new cases; 387.9 new cases per 100 000; a 73% increase), and Argentina (761 534 new cases; 1685.0 new cases per 100 000; similar to the figures of the previous week).

Over 19 000 new deaths were reported in the Region, corresponding to a 7% increase as compared to the previous week. The highest numbers of new deaths were reported from the United States of America (10 795 new deaths; 3.3 new deaths per 100 000; a 17% decrease), Brazil (1767 new deaths; <1 new death per 100 000; an 81% increase), and Mexico (1317 new deaths; 1.0 new deaths per 100 000; an 83% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported a continued increase in new cases this week, albeit at a lower rate when compared to the previous week; with over 479 000 new cases reported, a 39% increase. Half of the countries (13/22, 59%) reported increases of 20% or greater, with the highest increases reported from Iraq (38 623 vs 13 877 new cases; 178% increase), Afghanistan (870 vs 333 new cases; 161% increase) and the occupied Palestinian territory (7239 vs 3040 new cases; 140% increase). The highest numbers of new cases were reported from Tunisia (66 015 new cases; 558.6 new cases per 100 000; a 67% increase), Morocco (50 753 new cases; 137.5 new cases per 100 000; a 10% increase), and Lebanon (44 217 new cases; 647.8 new cases per 100 000; similar to the previous week's figures).

Over 1200 new deaths were reported in the Region, a 15% increase as compared to the previous week. The highest numbers of new deaths were reported from Egypt (207 new deaths; <1 new death per 100 000; a 12% increase), Tunisia (177 new deaths; 1.5 new deaths per 100 000; a 45% increase), and the Islamic Republic of Iran (158 new deaths; <1 new death per 100 000; a 20% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

Since mid-December 2021, the number of new cases has continued to rise, with the Region reporting over 10 million new cases this week, a 13% increase as compared to the previous week. Thirty-four countries (55%) reported an increase greater than 20%, with the greatest increases reported from Kosovo^[1] (13126 vs 2990 new cases; a 339% increase), the Republic of Moldova (19083 vs 8019 new cases; a 138% increase), and Armenia (4094 vs 1762 new cases; a 132% increase). The highest numbers of new cases were reported from France (2 443 821 new cases; 3757.4 new cases per 100 000; a 21% increase), Italy (1 231 741 new cases; 2065.2 new cases per 100 000; similar to the previous week's figures), and Germany (715 470 new cases; 860.3 new cases per 100 000; a 57% increase).

The number of weekly deaths in the Region decrease by 5%, with over 21 000 reported. The highest numbers of new deaths were reported from the Russian Federation (4792 new deaths; 3.3 new deaths per 100 000; a 7% decrease), Italy (2440 new deaths; 4.1 new deaths per 100 000; a 24% increase), and the United Kingdom (1888 new deaths; 2.8 new deaths per 100 000; similar to the previous week's figures).

Updates from the [European Region](#)

South-East Asia Region

The number of new cases in the South-East Asia Region increased for the third consecutive week, with over 2.3 million new cases reported this week, a 36% increase as compared to the previous week; this represents a slower rise compared to last week when the increase was 145%. Six out of ten countries in the region reported an increase greater than 20% in the number of new weekly cases, with the largest increases reported from Bhutan (721 vs 147 new cases; a 390% increase), Bangladesh (67 425 vs 24 011; a 181% increase) and Indonesia (14729 vs 5454 new cases; a 170% increase). The highest numbers of new cases were reported from India (2 115 100 new cases; 153.3 new cases per 100 000; a 33% increase), Bangladesh (67 425 new cases; 40.9 new cases per 100 000; a 181% increase), and Nepal (56 656 new cases; 194.4 new cases per 100 000; a 168% increase).

The number of new deaths in the Region increased by 44% as compared to the previous week, with over 3700 new deaths reported. The highest numbers of new deaths were reported from India (3343 new deaths; <1 new death per 100 000; a 47% increase), Thailand (107 new deaths; <1 new death per 100 000; a 7% increase), and Sri Lanka (88 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The number of new cases in Western Pacific Region has stabilized, with over one million new cases reported, similar to the previous week's figures. However, ten countries in the Region (36%) reported increases of over 20% in new cases, with the highest proportional increases reported from Palau (319 vs 46 new cases; a 593% increase), New Caledonia (1659 vs 518 new cases; a 220% increase) and Singapore (19290 vs 6184, a 211% increase). The highest numbers of new cases were reported from Australia (302 608 new cases; 1186.7 new cases per 100 000; a 36% decrease), Japan (268 284 new cases; 212.1 new cases per 100 000; a 181% increase), and the Philippines (219 146 new cases; 200.0 new cases per 100 000; a 5% decrease).

The number of new weekly deaths in the Region declined by 12% as compared with the previous week, with over 2500 new deaths reported. The highest numbers of new deaths were reported from Viet Nam (1116 new deaths; <1 new death per 100 000; an 18% decrease), the Philippines (548 new deaths; <1 new death per 100 000; a 24% decrease), and Australia (430 new deaths; 1.7 new deaths per 100 000; a 49% increase).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 25 January, highlights include the following:

- Partnering to bolster COVID-19 Response in Jamaica
- Leading the development of a comprehensive training package on bioinformatics and molecular epidemiology for SARS-CoV-2 and other high threat pathogens in Turkey
- Concluding a first-of-its-kind workshop for journalists and Ministry of Health communications focal points on public health information sharing and verification in Iraq
- Strengthening health systems in Timor-Leste to respond to pandemic
- Marking two years of pandemic learning response on OpenWHO.org
- Conducting a Joint Operational Review (JOR) in Nigeria
- Updates on WHO's financing to support countries on COVID-19 response implementation to suppress transmission, reduce exposure, and protect the vulnerable and save lives
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

*this variant was received by WHO from unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)*

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 75, published 18 January 2022

In this edition:

- [Global overview](#)
- [Special focus: Update on WHO COVID-19 global rapid risk assessment](#)
- [Special focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 16 January 2022

Globally, the number of new COVID-19 cases increased in the past week (10-16 January 2022), while the number of new deaths remained similar to that reported during the previous week (Figure 1). Across the six WHO regions, over 18 million new cases were reported this week, a 20% increase, as compared to the previous week. Over 45 000 new deaths were also reported (Table 1). As of 16 January 2022, over 323 million confirmed cases and over 5.5 million deaths have been reported worldwide.

Despite a slowdown of the increase in case incidence at the global level, all regions reported an increase in the incidence of weekly cases with the exception of the African Region, which reported a 27% decrease. The South-East Asia Region reported the largest increase in new cases last week (145%), followed by the Eastern Mediterranean Region (68%), the Western Pacific Region (38%), the Region of the Americas (17%) and the European Region (10%). New weekly deaths increased in the South-East Asia Region (12%) and Region of the Americas (7%), while remaining similar to the number reported during the previous week in the other Regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 16 January 2022**

**See [Annex 2: Data, table, and figure notes](#)

At the country level, the highest numbers of new cases were reported from the United States of America (4 688 466 new cases; similar to previous week's figures), France (2 012 943 new cases; a 26% increase), India (1 594 160 new cases; a 150% increase), Italy (1 268 153 new cases; a 25% increase), and the United Kingdom (813 326 new cases; a 33% decrease).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 16 January 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	8 281 997 (44%)	10%	119 133 975 (37%)	21 785 (48%)	3%	1 718 338 (31%)
Americas	7 198 756 (38%)	17%	118 339 517 (37%)	15 160 (33%)	7%	2 443 421 (44%)
South-East Asia	1 711 154 (9%)	145%	47 445 610 (15%)	2 579 (6%)	12%	726 828 (13%)
Western Pacific	1 011 609 (5%)	38%	13 135 837 (4%)	2 910 (6%)	5%	162 206 (3%)
Eastern Mediterranean	345 680 (2%)	68%	17 752 506 (5%)	1 071 (2%)	1%	318 268 (6%)
Africa	190 440 (1%)	-27%	7 802 161 (2%)	2 038 (4%)	-4%	160 619 (3%)
Global	18 739 636 (100%)	20%	323 610 370 (100%)	45 543 (100%)	4%	5 529 693 (100%)

Special Focus: Update on WHO COVID-19 global rapid risk assessment

The COVID-19 pandemic continues to evolve, as does our understanding of the SARS-CoV-2 virus, and the response needed to control the spread and impact of the virus. In WHO's most recent global rapid risk assessment, conducted on 07 January 2022, the global public health risk was assessed as remaining very high.

Under the [Emergency Response Framework](#), WHO undertakes risk assessments and situation analyses on a regular basis to inform our response to emerging situations. In addition, WHO periodically reviews the current risk status of ongoing public health events through an in-depth hazard, exposure and context assessment. This also includes a review of the vulnerabilities and capacities available to respond to the public health event and to investigate the current risk to human health, risks of ongoing global spread, and the risk of insufficient control capacities. Such assessments are used as an internal WHO decision-making tool, and to support independent deliberations, including but not limited to, meetings of the International Health Regulations (IHR 2005) Emergency Committee for the COVID-19 pandemic. To date, 13 global rapid risk assessments have been undertaken for COVID-19, and additional assessments have been conducted for specific events such as the emergence of SARS-CoV-2 variants. Here, we provide a synopsis of the most recent global rapid risk assessment for COVID-19 which covers the period from mid-October to the end of December 2021 and was finalised on 7 January 2022.

Since the [last risk assessment](#), the incidence of COVID-19 has increased globally, initially driven predominantly by transmission of the Delta variant, particularly in the European Region. Subsequently, following the identification of the Omicron variant in South Africa, reported to WHO on 24 November 2021, there has been a sharp increase in the incidence of cases in the African Region. This has been followed by increases in the other WHO Regions in weeks 51 (20-26 December 2021) and 52 (27 December 2021 to 2 January 2022). In contrast, a global decline has been seen for COVID-19 mortality since a peak in August 2021. Nonetheless, a combination of the increased and rapid spread of the Omicron variant, increased population movements and social mixing during and after the end of year holiday period and challenges with ongoing adherence to public health and social measures (PHSM) are expected to lead to increased number of cases, hospitalizations and deaths in the coming weeks.

On 26 November, WHO designated Omicron as the fifth SARS-CoV-2 Variant of Concern (VOC) due to its large number of mutations, evidence indicative of a detrimental change in COVID-19 epidemiology and potential for increased risk of reinfection. The variant has since spread to countries in all six WHO regions, replacing the Delta variant in most countries for which data are available. As the capacity for sequencing variants varies among countries, genomic surveillance of SARS-CoV-2 continues to be strengthened globally to ensure representative and timely reporting on the evolution of the virus and the emergence of variants.

Early evidence of the phenotypic impacts of the Omicron variant suggests a substantial growth advantage compared to the Delta variant. This may be attributed to immune evasion, increased intrinsic transmissibility, efficient replication in the upper respiratory tract or a combination of these factors, resulting in a large proportion of the population becoming infected or reinfected, even in countries with high levels of population immunity from previous infection and/or vaccination. Despite early data that suggest that the severity of infection associated with the Omicron variant is lower than that of Delta, the very large number of cases, including amongst healthcare workers, has resulted in a substantial number of people requiring hospitalization, putting pressure on healthcare systems. Because of this, countries have been urged to develop mitigation plans to maintain essential health services which faced significant disruption during previous surges of COVID-19.

As of 29 December 2021, 8.6 billion doses of vaccine have been administered globally; 57% of the global population has received at least one dose and 47% have completed the primary vaccination series. The distribution of vaccines

remains unequal. As of 15 December, only 9% of those in low-income countries have received at least one dose, compared to 66% in high-income countries. Supply to low-income countries is expected to increase rapidly in 2022 through the COVAX and African Vaccine Acquisition Trust (AVAT), however, absorption remains a challenge with countries struggling to manage unpredictable deliveries with a short shelf-life. Additionally, vaccine hesitancy persists in a number of settings. Vaccines continue to protect against severe disease for both VOCs and non-VOCs, however, there is evidence of a reduction in vaccine effectiveness over time due to waning of the humoral immune response. WHO recommends an additional dose for those who are immunocompromised and did not respond sufficiently to initial doses in the primary series or who are no longer producing antibodies, and those aged 60 years and over who received primary vaccination with one of inactivated products (CoronaVac or the COVID-19 vaccine BIBP); however, more data are needed on the optimal timing, safety and dosage of booster doses. Individual countries need to balance decisions about their booster dose policy and local public health benefits against the need to support global equity in vaccine access.

There remain knowledge gaps in the phenotypic impact of identified and emerging variants (including the Omicron variant), the waning of the humoral immune response, and changes in the severity profile of VOCs, including amongst children and adolescents.

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the emergence and rapid spread of the Omicron variant on a global scale, continued decline in the prevalence of the Delta variant, and a very low level of circulation of the Alpha, Beta and Gamma variants. Following the identification of travel-related cases of the Omicron variant, many countries are now reporting community transmission. Countries that experienced a rapid rise in Omicron cases in November and December 2021 are beginning to see declines in cases. The Omicron variant includes Pango lineages B.1.1.529, BA.1, BA.2 and BA.3. BA.1 accounts for >99% of sequences submitted to GISAID as of 18 January 2022. All these variants are being monitored by WHO under the umbrella of 'Omicron'.

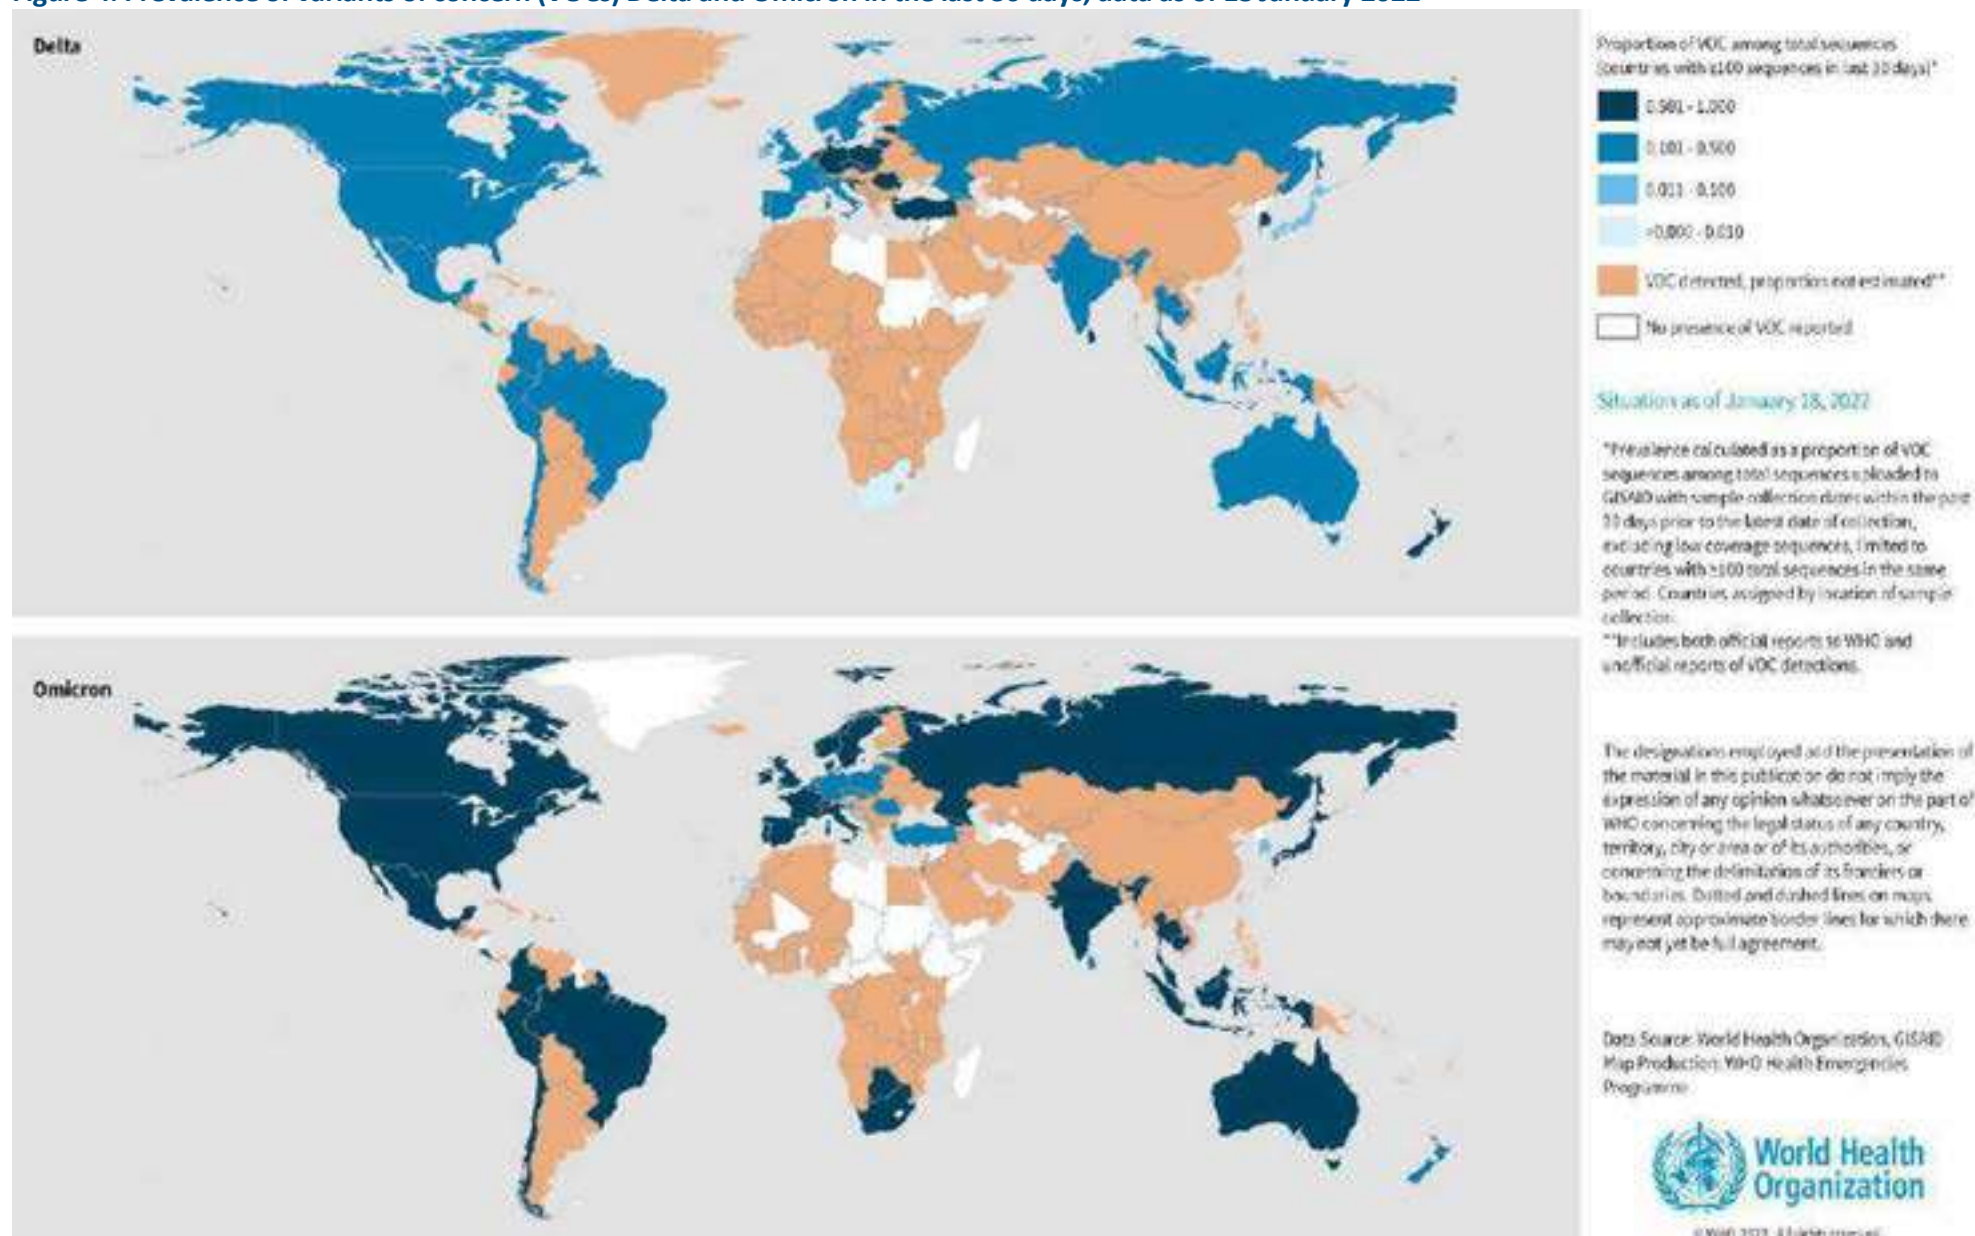

Among the 405 739 sequences uploaded to [GISAID](#) with specimens collected in the last 30 daysⁱ, 291 600 sequences (71.9%) were Omicron, 113 652 (28%) were Delta, 47 (<0.1%) were Gamma, ten (<0.1%) were Alpha and three sequences (<0.1%) comprised other circulating variants (including VOIs Mu and Lambda). To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Additional resources

- Detailed technical evidence on phenotypic impacts of the Omicron can be found in the [Weekly Epidemiological Update](#) and in the [Technical briefing on Omicron SARS-CoV-2 variant published on 7 January 2022](#).

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 16 December 2021 to 14 January 2022 (last reported sample at the time of data extraction), excluding low coverage sequences.

Figure 4: Prevalence of variants of concern (VOCs) Delta and Omicron in the last 30 days, data as of 18 January 2022

See also [Annex 1](#) for reported VOC detections by country/territory/area

African Region

The number of new cases in the Africa Region continues to decline following the most recent peak in December 2021, with over 190 000 new cases reported, a 27% decrease as compared to the previous week. While most countries in the region reported a decline in the number of new cases, nearly a third of the countries in the region (13/41; 32%) reported an increase of 10% or more as compared to the previous week. The largest proportional increase in cases was observed in Mayotte (9086 vs 2760 new cases, a 229% increase), Central African Republic (865 vs 291; 197%) and Eritrea (573 vs 277; 107%). The highest numbers of new cases were reported from South Africa (35 121 new cases; 59.2 new cases per 100 000 population; a 34% decrease), Réunion (16 256 new cases; 1815.7 new cases per 100 000; a 74% increase), and Zambia (13 452 new cases; 73.2 new cases per 100 000; a 43% decrease).

The number of new deaths reported in the Region was just over 2000, similar to the number reported during the previous week. The highest numbers of new deaths were reported from South Africa (907 new deaths; 1.5 new deaths per 100 000 population; a 23% decrease), Ethiopia (111 new deaths; <1 new death per 100 000; a 52% increase), and Namibia (106 new deaths; 4.2 new deaths per 100 000; a 63% increase).

Updates from the [African Region](#)

Region of the Americas

The number of new cases in the Region of the Americas increased, albeit at a slower rate, in the past week, with just under 7.2 million new cases reported, a 17% increase as compared to the previous week. The majority of the countries in the Region reported increases of over 10% (39/56; 70%). The countries with the highest proportionate increases were Martinique (13 540 vs 1385; 638%) El Salvador (1343 vs 289; 365%) and Ecuador (42 992 vs 10 532; 308%). The highest numbers of new cases were reported from the United States of America (4 688 466 new cases; 1416.4 new cases per 100 000; similar to the previous week's figures), Argentina (797 136 new cases; 1763.7 new cases per 100 000; a 73% increase), and Brazil (476 981 new cases; 224.4 new cases per 100 000; a 193% increase).

The number of new deaths also increased in the past week, with over 15 000 new deaths, a 7% increase as compared to the number reported during the previous week. The highest numbers of new deaths were reported from the United States of America (10 412 new deaths; 3.1 new deaths per 100 000; a 5% decrease), Brazil (974 new deaths; <1 new death per 100 000; a 27% increase), and Canada (523 new deaths; 1.4 new deaths per 100 000; a 50% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region showed a substantial increase in new cases reported during this past week, with over 345 000 new cases, a 68% increase as compared to the previous week. All but two countries (Libya and Somalia) in the Region reported increases in the number of new cases in the past week. The highest numbers of new cases were reported from Morocco (46 104 new cases; 124.9 new cases per 100 000; a 45% increase), Lebanon (45 231 new cases; 662.7 new cases per 100 000; a 19% increase), and Tunisia (39 487 new cases; 334.1 new cases per 100 000; a 194% increase).

The number of new deaths remained similar to the number reported during the previous week, with just over 1000 new deaths reported. The highest numbers of new deaths were reported from the Islamic Republic of Iran (197 new deaths; <1 new death per 100 000; a 5% decrease), Egypt (185 new deaths; <1 new death per 100 000; a 9% increase), and Tunisia (122 new deaths; 1.0 new deaths per 100 000; a 54% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

The number of new cases continued to increase this week in the European Region with over 8.2 million new cases reported, a 10% increase as compared to the previous week. Most of the countries in the Region (39/61; 64%) reported an increase greater than 10%, with the highest increases reported from Kazakhstan (54 927 vs 6672 new cases, a 723% increase), Uzbekistan (4744 vs 1223 new cases, a 287% increase) and Kosovo^[1] (2990 vs 842 new cases, a 255% increase). The highest numbers of new cases were reported from France (2 012 943 new cases; 3095.0 new cases per 100 000; a 26% increase), Italy (1 268 153 new cases; 2126.3 new cases per 100 000; a 25% increase), and the United Kingdom (813 326 new cases; 1198.1 new cases per 100 000; a 33% decrease).

The number of weekly deaths was similar to the previous week, with over 21 000 new deaths reported. The highest numbers of new deaths were reported from the Russian Federation (5157 new deaths; 3.5 new deaths per 100 000; a 9% decrease), Poland (2563 new deaths; 6.8 new deaths per 100 000; a 19% increase), and Italy (1975 new deaths; 3.3 new deaths per 100 000; a 44% increase).

Updates from the [European Region](#)

South-East Asia Region

The number of new cases in the South-East Asia Region continues to increase, with over 1.7 million new cases reported, a 145% increase as compared to the previous week. All but one country (Timor-Leste; a 58% decrease) reported an increase in the number of new weekly cases, with the largest proportional increases observed in Nepal (21149 vs 3603 new cases, a 486% increase), Bangladesh (24011 vs 7234; a 231% increase) and the Maldives (5529 vs 2000, a 176% increase). The highest numbers of new cases were reported from India (1 594 160 new cases; 115.5 new cases per 100 000; a 150% increase), Thailand (54 935 new cases; 78.7 new cases per 100 000; a 37% increase), and Bangladesh (24 011 new cases; 14.6 new cases per 100 000; a 232% increase).

Over 2500 new weekly deaths were reported, a 12% increase as compared to the previous week. The highest numbers of new deaths were reported from India (2276 new deaths; <1 new death per 100 000; a 13% increase), Thailand (100 new deaths; <1 new death per 100 000; a 5% decrease), and Sri Lanka (92 new deaths; <1 new death per 100 000; an 8% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The numbers of new weekly cases and deaths have continued to increase in the Western Pacific Region, with over one million new cases and over 2900 new deaths, increases of 38% and 5% increase respectively as compared to the previous week. Twelve countries in the Region (44%), reported increases of over 10% in new cases, with the highest increases reported from Palau (46 vs 5 new cases; an 820% increase), French Polynesia (475 vs 109 new cases; a 335% increase) and Japan (95498 vs 23168; a 312% increase). The highest numbers of new cases were reported from Australia (472 564 new cases; 1853.2 new cases per 100 000; a 12% increase), the Philippines (231 502 new cases; 211.3 new cases per 100 000; a 159% increase), and Viet Nam (131 468 new cases; 135.1 new cases per 100 000; similar to the previous week's figures).

The highest numbers of new deaths were reported from Viet Nam (1363 new deaths; 1.4 new deaths per 100 000; a 10% decrease), the Philippines (723 new deaths; <1 new death per 100 000; a 23% increase), and Australia (288 new deaths; 1.1 new deaths per 100 000; a 213% increase).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 18 January, highlights include the following:

- Supporting COVID-19 control measures in Islamic Republic of Iran with donation of new equipment
- Providing continued support to countries on the detection of Variants of Concern (VOC) in the European Region
- COVAX delivering its 1 billionth COVID-19 vaccine dose
- Providing lifesaving medical-grade oxygen to the Philippines to fight against new COVID-19 variants
- Supporting prevention measures and COVID-19 vaccination for migrants struggling during lockdown in Thailand
- Mitigating the COVID-19 outbreak through global data sharing: The WHO Global Clinical Platform for COVID-19 Call to action
- Updates on WHO's financing to support countries on COVID-19 response implementation to suppress transmission, reduce exposure, and protect the vulnerable and save lives
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

Information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 74, published 11 January 2022

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 variants of interest and variants of concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 9 January 2022

Globally, the number of new cases increased markedly in the past week (3-9 January 2022), while the number of new deaths remained similar to that of the previous week. Across the six regions, over 15 million new cases were reported this past week, a 55% increase as compared to the previous week and over 43 000 new deaths were reported. As of 9 January, over 304 million confirmed cases and over 5.4 million deaths have been reported.

All regions reported an increase in the incidence of weekly cases with the exception of the African Region, which reported an 11% decrease. The South-East Asia region reported the largest increase in new cases last week (418%), followed by the Western Pacific Region (122%), the Eastern Mediterranean Region (86%), the Region of the Americas (78%) and the European Region (31%). New weekly deaths increased in the African Region (84%) and Region of the Americas (26%). The number of new deaths remained similar to that of the previous week in the Western Pacific Region, while a decrease was reported in the Eastern Mediterranean Region (11%), the European Region (10%) and in the South-East Asia Region (6%).

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 9 January 2022**

**See [Annex 3: Data, table, and figure notes](#)

The regions reporting the highest weekly case incidence per 100 000 population continue to be the European Region (765.8 new cases per 100 000 population) and the Region of the Americas (597.9 new cases per 100 000 population). Both regions also reported the highest weekly incidence in deaths of 2.2 and 1.4 per 100 000 population, respectively, while <1 new death per 100 000 was reported in all other regions.

The highest numbers of new cases were reported from the United States of America (4 610 359 new cases; a 73% increase), France (1 597 203 new cases; a 46% increase), the United Kingdom (1 217 258 new cases; a 10% increase), Italy (1 014 358 new cases; a 57% increase), and India (638 872 new cases; a 524% increase).

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by the emergence of Omicron variant, declining prevalence of the Delta variant, and very low level circulation of Alpha, Beta and Gamma variants. Following the identification of travel related Omicron cases, many countries are now reporting clusters as well as community transmission of this VOC. Among the 357 206 sequences uploaded to [GISAID](#) with specimens collected in the last 30 daysⁱ, 208 870 sequences (58.5%) were Omicron, 147 887 (41.4%) were Delta, 12 (<0.1%) were Alpha, two (<0.1%) were Gamma, one (<0.1%) was Beta and six sequences (<0.1%) comprised other circulating variants (including VOIs Mu and Lambda). To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Differences in the characteristics of VOCs

Available evidence on the phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last update on 14 December 2021](#), there are several new publications on the phenotypic characteristics of VOCs, including recent literature on Omicron. Some of the studies reported have not been peer-reviewed and the findings must therefore be interpreted with due consideration of this limitation.

Update on Omicron VOC

The Omicron variant has a substantial growth advantage and is rapidly replacing other variants. This variant has been shown to have a shorter doubling time as compared to previous variants, with transmission occurring even amongst those vaccinated or with a history of prior SARS-CoV-2 infection; there is increasing evidence that this variant is able to evade immunity.¹⁻⁴ In Denmark, the first case of infection with the Omicron variant was detected on 22 November 2021, with community transmission established by late November 2021. A non-peer-reviewed preprint used Danish registers to estimate the household secondary attack rate (SAR) among Danish households during December 2021. The SAR was 31% versus 21% in households with the Omicron (total primary cases: 2225) and Delta variant (total primary cases: 9712), respectively, with the estimated SAR remaining higher for the Omicron than for the Delta variant across all groups.³ Additionally, unvaccinated households had a 1.17 (95%CI: 0.99-1.38) times higher SAR when infected with the Omicron compared to Delta variant, while vaccinated individuals and individuals who had

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 12 December 2021 to 10 January 2022 (last reported sample at the time of data extraction), excluding low coverage sequences.

received a booster dose had 2.61 times (95%-CI: 2.34-2.90) and 3.66 times (95%-CI: 2.65-5.05) higher SAR respectively, providing evidence as to the ability of the Omicron variant to evade immunity (note that the absolute risk of infection remained lower in vaccinated individuals than unvaccinated individuals).

In terms of disease severity, there is growing evidence that the Omicron variant is less severe as compared to other variants.⁵⁻⁸ A non-peer-reviewed preprint from Gauteng province, South Africa which documented the first rapid increases in case incidence due to the Omicron variant, compared the clinical severity of patients hospitalised with SARS-CoV-2 infection from 14 November until 11 December 2021 (a period during which Omicron became the dominant circulating variant) with periods when the Beta and Delta variants were the dominant variants (29 November to 26 December 2020 and 2 May to 29 May 2021, respectively).⁹ Despite the higher number of cases during the 'Omicron-dominant' period, hospital admission rates were lower, with 4.9% of cases admitted as compared with 18.9% admitted during the 'Beta-dominant' period and 13.7% during the 'Delta-dominant' period. Similarly, fewer patients developed severe disease during the latter period (28.8%; 1,276/4,438) as compared to the Beta (60.1%; 4,672/7,774) and Delta (66.8%; 3,058/4,574) periods. In this study, severe disease was defined as one or more of the following: development of acute respiratory distress syndrome, supplemental oxygen or invasive mechanical ventilation, treatment in high care or the intensive care unit, or death. Additionally, patients admitted during the 'Omicron-dominant period' were 73% less likely to have severe disease than patients admitted during the 'Delta-dominant period' (Adjusted Odds Ratio 0.27, 95% CI 0.25-0.31).

A non-peer-reviewed retrospective cohort study from the United States of America, where the Omicron variant has been detected since December 2021, used propensity-score matching on demographic characteristics, comorbidities, medications,, vaccination status and other socio-economic determinants of health to compare the 3-day risk (time window from the first day of SARS-CoV-2 infection identification to three days after infection) of adverse outcomes following infection with SARS-CoV-2.⁸ The outcomes, visiting the emergency department (ED), hospitalization, ICU admission, and mechanical ventilation, were compared between the two cohorts. These cohorts included those infected with SARS-CoV-2 between 15 and 24 December 2021 when the Omicron variant was dominant, the 'Omicron cohort' (n=14 054) and those infected between 1 September and 15 December 2021 when the Delta variant was dominant (n=563 884), the 'Delta cohort'. Compared to the Delta cohort, the risk of an adverse outcome in the Omicron cohort was lower, including admission to ED (Risk Ratio [RR] 0.30, 95%CI 0.28-0.33); hospitalization (RR 0.44, 95%CI 0.38-0.52); ICU admission (RR 0.33, 95%CI 0.23-0.48) and mechanical ventilation (RR 0.16, 95%CI 0.08-0.32). Similarly, the risk of attending the ED or of hospitalization was lower amongst those under 5 years old in the Omicron as compared to Delta cohort (RR=0.19, 95%CI 0.14-0.25 and RR=0.36, 95%CI 0.19-0.68, respectively). These findings suggests that while the absolute number of cases and hospitalizations among children are currently increasing in the United States of America, the risk of hospitalization still remains lower compared to other age groups during the period when Omicron is circulating as compared to the period when the Delta variant was dominant.

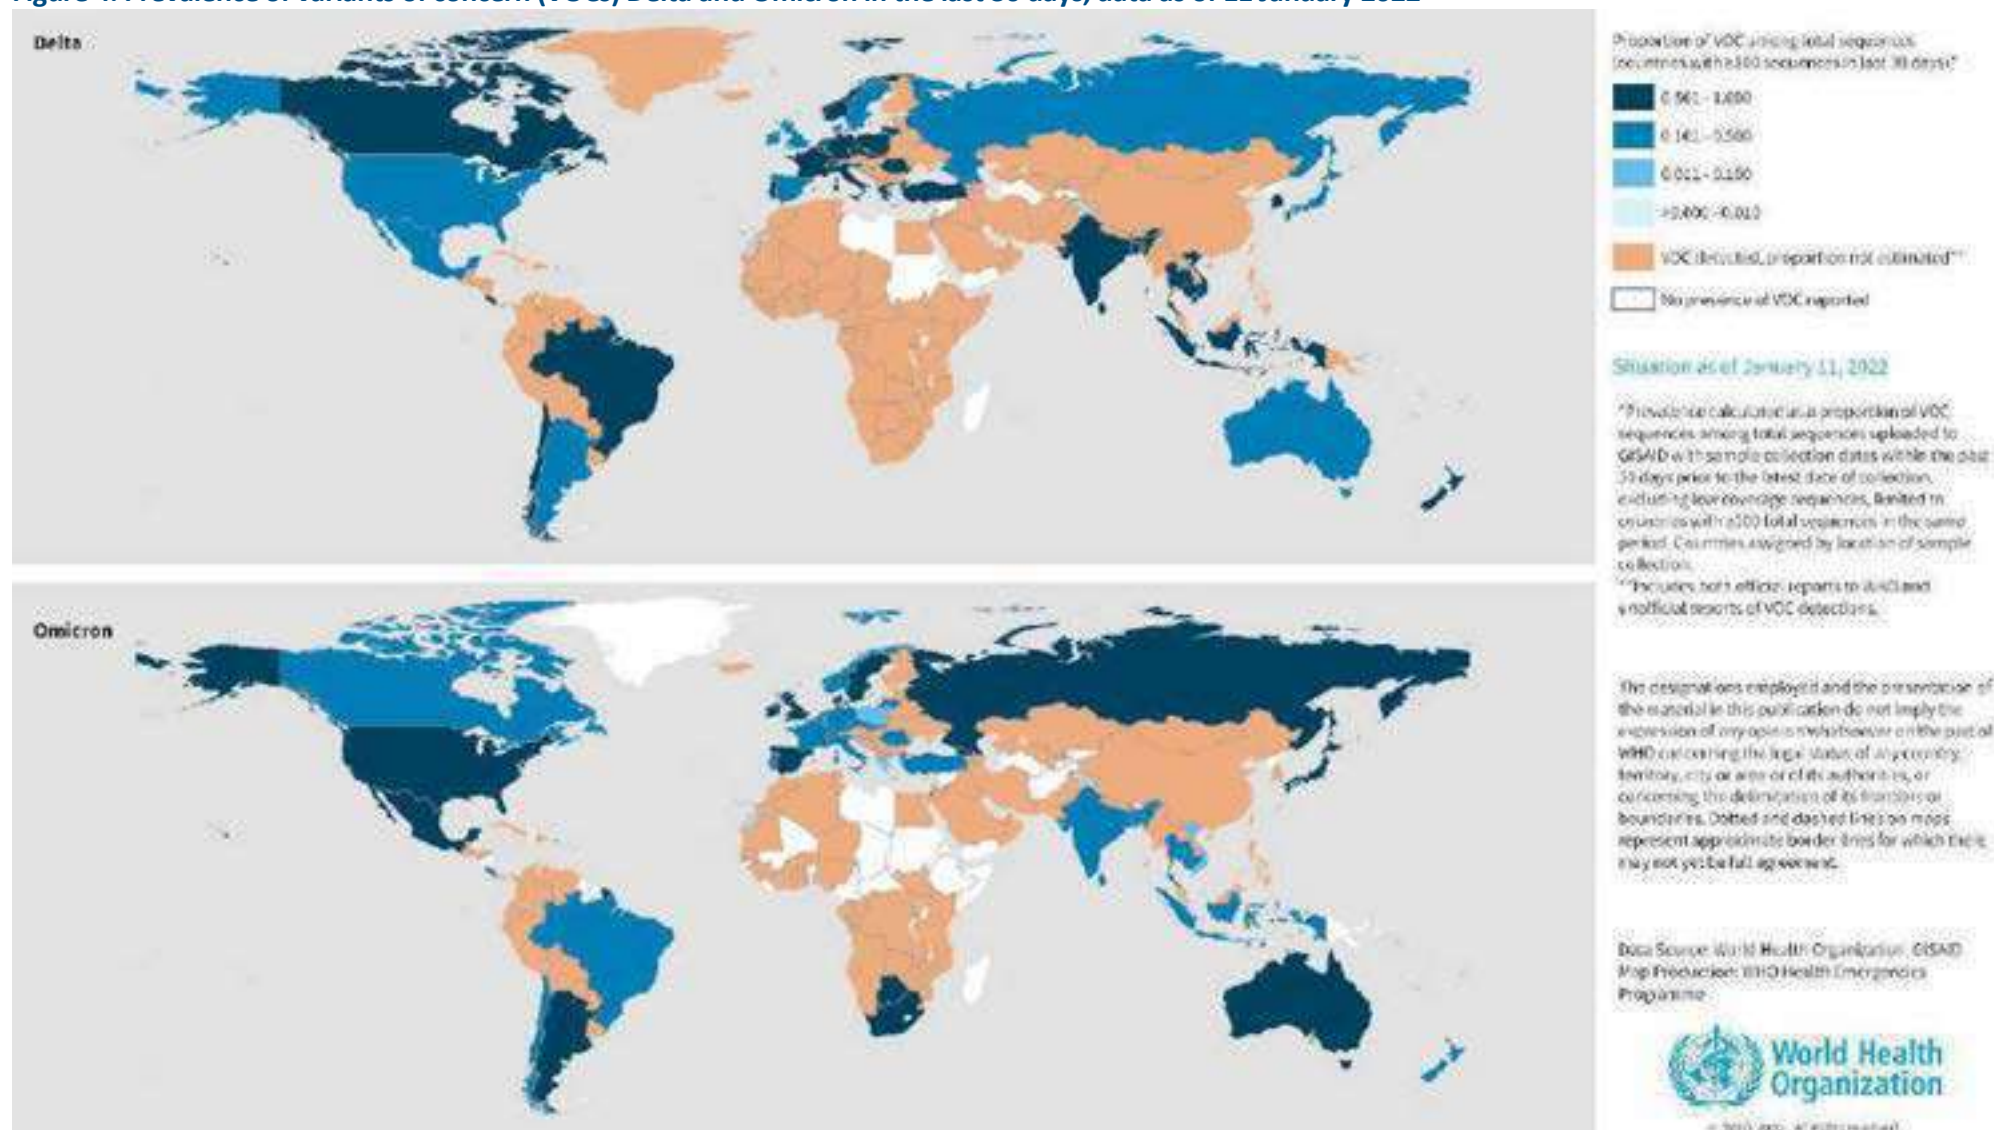

A small cohort study (not yet peer-reviewed) conducted in South Africa of 15 individuals showed that infection with the Omicron variant enhanced an individual's neutralizing antibody immune response against the Delta variant.¹⁰ The study enrolled previously vaccinated and unvaccinated individuals who were infected with SARS-CoV-2 during the period when the Omicron variant was dominant(n=13). Participants were sampled at enrollment, which was a median of four days post-symptom onset and again at a median of 14 days post-enrollment. Two participants did not neutralize Omicron at either timepoint and were excluded from the analysis. Two of the remaining 13 participants did not have detectable SARS-CoV-2 at enrollment, indicating that infection was already cleared, and therefore, that these participants were sampled later post-infection. The blood from the participants was used to neutralize both Omicron and Delta variants at enrollment and a median of 14 days after enrollment. A 14.4-fold increase (95% CI 5.5-37.4) in the geometric mean titer (GMT) of the focus reduction neutralization test (FRNT₅₀) (20 to 285) was seen between enrollment and the later visit for the Omicron variant and a 4.4-fold increase (95%CI 2.1-9.2) in the GMT of the FRNT₅₀ for the Delta variant (80 to 354). This study provides early evidence on a small cohort

which suggests that there may be an increase in Delta variant neutralization in individuals infected with Omicron, which may result in decreased ability of Delta to re-infect those individuals.

A case-control test-negative study (not yet peer-reviewed) estimated the effectiveness of prior infection with SARS-CoV-2 in preventing reinfection with the Omicron and other variants in Qatar, with the hypothesis that protection against reinfection with Omicron was lower than for other variants.¹¹ Cases (those who were PCR-positive for SARS-CoV-2) and controls (those who were PCR-negative) were matched by sex, 10-year age group, nationality, and calendar time of the PCR test, to control for known differences in the risk of exposure to SARS-CoV-2 infection. Prevention against symptomatic reinfection was estimated at 90.2% (95% CI: 60.2-97.6) for the Alpha variant, 84.8% (95% CI: 74.5-91.0) for the Beta variant, 92.0% (95% CI: 87.9-94.7) for the Delta variant, and 56.0% (95% CI: 50.6-60.9) for the Omicron variant. Prevention against hospitalization or death due to reinfection was estimated at 69.4% (95% CI: -143.6-96.2) for the Alpha variant, 88.0% (95% CI: 50.7-97.1) for the Beta variant, 100% (95% CI: 43.3-99.8) for the Delta variant, and 87.8% (95% CI: 47.5-97.1) for the Omicron variant. This study suggested that protection afforded by prior infection in preventing symptomatic reinfection with Alpha, Beta, or Delta was robust; while such protection against reinfection with Omicron was lower, at nearly 60%. Prior-infection protection against hospitalization or death at reinfection remained robust regardless of variant.

These are all preliminary results which may not represent the overall phenotypic and clinical profile of the Omicron variant and will possibly change as more evidence becomes available in the coming weeks. As a result of this, the overall risk related to Omicron remains very high. More information on the Omicron variant can be found in the updated [Technical Brief and Priority Actions for Member States](#) dated 7 January 2022 by WHO.

Figure 4: Prevalence of variants of concern (VOCs) Delta and Omicron in the last 30 days, data as of 11 January 2022

See also [Annex 2](#) for reported VOC detections by country/territory/area

Table 2: Summary of phenotypic impacts* of variants of concern

WHO label	Alpha	Beta	Gamma	Delta	Omicron
Transmissibility	Increased transmissibility ¹²	Increased transmissibility ^{13,14}	Increased transmissibility ^{14,15}	Increased transmissibility ^{14,16,17}	Increased transmissibility. ^{1–4}
Disease severity	Possible increased risk of hospitalization ^{18,19} , possible increased risk of severe disease and death ^{20,21}	Possible increased risk of hospitalization ¹⁹ , possible increased in-hospital mortality ²²	Possible increased risk of hospitalization ¹⁹ , possible increased risk of severe disease ²³	Possible increased risk of hospitalization ^{24,25}	Possible reduced risk of hospitalization and severe disease ^{5–8}
Risk of reinfection	Neutralizing activity retained ²⁶ , risk of reinfection remains similar ²⁷	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²⁸	Moderate reduction in neutralizing activity reported ²⁹	Reduction in neutralizing activity reported ^{30–32}	Increased risk of reinfection ^{11,33}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ³⁴	No impact on RT-PCR or Ag RDTs observed ³²	None reported to date	No impact on RT-PCR or Ag RDTs observed ³⁵	PCR continues to detect Omicron. Impact on Ag-RDTs is under investigation: Results are mixed as to whether or not there may be decreased sensitivity to detect Omicron. ^{1,8,36–38}

*Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.

Table 3 summarizes the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to non-VOC settings. Here, we review studies assessing VE against Delta and Omicron variants of concern only. Since the 14 December update, we report on a total of 13 new studies that provided evidence of COVID-19 vaccine effectiveness against Delta and Omicron.

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

Omicron VOC

Since the [last update on 14 December](#), six studies have provided evidence of reduced vaccine effectiveness (VE) of COVID-19 vaccines against the Omicron variant. Four of these studies provide the first estimates of VE against severe disease associated with the Omicron variant.

A peer-reviewed test-negative case control study from South Africa analyzed 133 437 PCR test results among adults aged 18 years and older and found reduced VE of Pfizer BioNTech-Comirnaty against hospitalization ≥ 14 days after receipt of the second dose during the period 15 November– 7 December 2021 when Omicron was the dominant circulating variant.⁴⁶ VE against hospitalization during this period was 70% (95% CI: 62 to 76%) as compared to 93% (90-94%) during the period of 1 September to 31 October 2021 when Delta was the dominant variant in circulation.

A second test-negative study (not yet peer reviewed) assessed VE of a booster dose of Janssen-Ad26.COVS against hospitalization due to Omicron among healthcare workers in South Africa.⁴⁷ VE of two doses of Janssen-Ad26.COVS against hospitalization with Omicron 14-27 days post booster as compared to unvaccinated healthcare workers was 84% (67 to 92%), which was maintained 1-2 months after a booster.

A third test-negative case-control study from the United Kingdom (not yet peer reviewed) found a combined VE of either the Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273 or AstraZeneca-Vaxzevria vaccines against hospitalization due to infection with the Omicron variant, of 72% (55 to 83%) 2-24 weeks after receipt of a second dose. This declined to 52% (21-71%) after 25 weeks following the second dose.⁴⁸ However, the contribution of each vaccine to the VE was unknown. A booster dose of mRNA vaccine increased VE against hospitalization ≥ 14 days after vaccination to 88% (78 to 93%).

A fourth test-negative case-control study from the United States of America (not yet peer-reviewed) assessed the effectiveness of Moderna-mRNA-1273 at preventing hospitalization due to Omicron and Delta among members aged 18 years and older of a large healthcare system during 16 to 23 December 2021.⁴⁹ Though numbers were too small to estimate the VE against hospitalization due to Omicron and adjusted for important confounders, the authors report an *unadjusted* VE of 16.5% (0-89.1%) for two doses and 100% (95% CI not available due to no cases in the vaccinated group) for three doses; adjusted VE of two doses against hospitalization due to Delta was 98.0% (87.2 to 99.7%). The maximum potential follow-up time from second and third dose was approximately 11 months and two months, respectively. This study also assessed VE of Moderna-mRNA-1273 against infection due to Omicron. Adjusted VE 14-90 days post second dose was 30.4% (5.0 to 49.0%) and fell to 0% by 6 months post second dose. Among immunocompetent persons who had received a third vaccine dose after 20 October 2021, VE against Omicron was 63.6% (57.4 to 61.5%) with a median follow-up time of 36 days. VE of three doses of Moderna-mRNA-1273 against Omicron infection was substantially lower when restricting to immunocompromised persons (VE: 11.5%, 95% CI: 0 to 66.5%). VE of two doses of the vaccine against infection due to Delta was substantially higher than that for Omicron, but also showed declined over time since second dose. VE at 14-90 days and 271-365 days among vaccinated was 82.8% (69.6 to 90.3%) and 52.9% (43.7 to 60.5%), respectively. VE of three doses against Delta infection for persons receiving their booster dose after 20 October 2021 was 95.7% (94.2 to 96.8%).

A fifth test-negative study (not yet peer reviewed) assessed VE of Pfizer BioNTech-Comirnaty against infection due to Omicron and Delta among persons aged 18 years and older in Canada.⁵⁰ The findings showed that Pfizer BioNTech-Comirnaty was not effective at preventing infection with Omicron 7-59 days following receipt of the second dose (VE: -2%, 95% CI: -38% to 25%). VE against infection due to Omicron increased but remained low after ≥ 7 days of receiving the booster dose of Pfizer BioNTech-Comirnaty (37%, 95%: 18 to 51%). The same study found that VE against infection due to Delta remained high at 82% (79 to 85%) 7-59 days after the second dose of Pfizer BioNTech-

Comirnaty but declined to 66% (60 to 71%) by eight months post second dose. Receipt of a third dose of the vaccine increased VE against Delta to 93% ≥ 7 days after receiving the vaccine (91 to 94%).

While early VE estimates against the Omicron variant should be interpreted with caution due to potential biases, these preliminary results provide evidence of reduced overall effectiveness of vaccines against the Omicron variant, with greater declines in effectiveness with increasing time since vaccination, relative to Delta. These VE findings are consistent with findings from recent neutralization studies (see table 3). While a booster vaccination appears to improve VE against infection and hospitalization due to the Omicron variant, more data are needed to assess both the magnitude and duration of the protection.

Delta VOC

Several additional studies have assessed the effectiveness of COVID-19 vaccines against the Delta variant. A retrospective cohort study (not yet peer reviewed) conducted among a cohort of healthcare worker in South Africa during a period when the Delta variant was the dominant variant found the Janssen-Ad26.COV2.S vaccine to be 67% (62 to 71%) and 82% (74 to 89%) effective at preventing hospitalization and death, respectively, over a median follow-up time of 3.6 months.⁵¹ Another retrospective study among adults in Scotland, the United Kingdom, during a Delta dominant period found the AstraZeneca-Vaxzevria vaccine to be 83.7% (79.7 to 87.0%) effective at preventing hospitalization or death 14-27 days after receipt of second dose, with VE decreasing to 53.6% (48.4 to 58.3%) approximately five months after.⁵²

Five new studies assessed the ability of a booster dose of mRNA vaccines to prevent infection and disease due to the Delta variant. A retrospective cohort study from Singapore (not yet peer reviewed) found an increased vaccine effectiveness of three doses of Pfizer BioNTech-Comirnaty and Moderna-mRNA-1273 *relative to two doses* of each vaccine during a period when Delta was dominant.⁵³ The VE of three versus two doses of Pfizer BioNTech-Comirnaty against infection, symptomatic disease, and severe disease was 73% (71 to 74%), 72% (71 to 74%), and 95% (92 to 97%), respectively. A booster dose of Moderna-mRNA-1273 after Pfizer BioNTech-Comirnaty primary series resulted in higher VE estimates for infection (82%), symptomatic disease (82%) and severe disease (92%) compared to receiving a booster of Pfizer BioNTech-Comirnaty. The VE of three compared to two doses of Moderna-mRNA-1273 against infection and symptomatic disease was 86% (81 to 90%) and 85% (79 to 89%), with no estimate available for severe disease. The maximum potential follow-up time from receipt of booster dose for this study was six weeks.

To date many studies have provided evidence of high VE against the Delta variant, especially against severe disease due to Delta, with VE decreasing over time among vaccinated people. These recent studies provide further evidence that booster vaccination may improve VE against Delta, although more data are needed to fully assess the duration of protection.^{54–58}

African Region

After showing a continuous increase in weekly cases for six weeks, the African Region reported an 11% decrease in weekly cases as compared to the previous week, with over 260 000 new cases reported this week. This decrease was mainly driven by decreases in new weekly cases reported by Mozambique (17 667 vs 26, 860 new cases) and South Africa (53 433 vs 60 142 new cases). However, one-third of countries (16/49), still reported increases of over 50%. The highest numbers of new cases were reported from South Africa (53 433 new cases; 90.1 new cases per 100 000 population; an 11% decrease), Zambia (23 628 new cases; 128.5 new cases per 100 000; a 10% decrease), and Ethiopia (18 999 new cases; 16.5 new cases per 100 000; a 34% decrease).

The number of new weekly deaths continues to increase in the Region, with over 2100 new deaths reported this week, an 84% increase as compared to the previous week. This increase is largely due to retrospective reporting of 500 deaths on 6 January, resulting in an increase in weekly deaths of 176%. The highest numbers of new deaths were reported from South Africa (1173 new deaths; two new deaths per 100 000 population; a 176% increase), Zimbabwe (131 new deaths; <1 new death per 100 000; a 1% decrease), and Madagascar (90 new deaths; <1 new death per 100 000; a 190% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas has continued to report an increasing trend in weekly cases for over a month, with the highest number of weekly cases (over six million new cases) ever reported this week, a 78% increase as compared to the previous week. The Region also reported over 14 000 new deaths, a 25% increase as compared to the previous week. This increase in weekly cases and deaths is mainly driven by large increases in the United States of America with four additional countries (80%) reporting an increase of 50% or more compared to the previous week.

The highest numbers of new cases were reported from the United States of America (4 610 359 new cases; 1392.8 new cases per 100 000; a 73% increase), Argentina (461 408 new cases; 1020.9 new cases per 100 000; a 101% increase), and Canada (254 299 new cases; 673.8 new cases per 100 000; a 15% increase). The highest numbers of new deaths were reported from the United States of America (11 182 new deaths; 3.4 new deaths per 100 000; a 26% increase), Brazil (766 new deaths; <1 new death per 100 000; a 15% increase), and Mexico (560 new deaths; <1 new death per 100 000; a 28% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 200 000 new cases and over 1000 new deaths, an 86% increase and an 11% decrease, respectively as compared to the previous week. This week, 35% of all new cases were reported from two countries including Lebanon (38,112 new cases) and Morocco (31,701 new cases). In the past week, 12 countries in the Region (57%) reported an increase of 50% or greater in the number of new cases, with Kuwait reporting the highest proportional increase in cases (2812 vs 13 197 new cases, a 369% increase). The highest numbers of new cases were reported from Lebanon (38 112 new cases; 558.4 new cases per 100 000; a 90% increase), Morocco (31 701 new cases; 85.9 new cases per 100 000; a 222% increase), and the United Arab Emirates (18 373 new cases; 185.8 new cases per 100 000; a 23% increase). These countries account for almost half (44%) of all new cases in the Region.

The highest numbers of new deaths were reported from the Islamic Republic of Iran (208 new deaths; <1 new death per 100 000; a 29% decrease), Jordan (172 new deaths; 1.7 new deaths per 100 000; a 28% decrease), and Egypt (170 new deaths; <1 new death per 100 000; a 14% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The number of new cases continued to increase this week in the European Region with over 7.1 million new cases reported, a 31% increase as compared to the previous week. However, the number of weekly deaths continued to decline with over 20 000 new deaths reported, a 10% decrease as compared to the previous week. In the past week, 27 countries in the Region (44%) reported an increase of 50% or greater in the number of new cases with the highest increases reported from Kosovo^[1] (842 vs 204 new cases, a 313% increase), Greenland (1883 vs 475 new cases, a 296% increase) and Israel (100 353 vs 26 913 new cases, a 273% increase). The highest numbers of new cases were reported from France (1 600 121 new cases; 2460.2 new cases per 100 000; a 46% increase), the United Kingdom (1 217 258 new cases; 1793.1 new cases per 100 000; a 10% increase), and Italy (1 014 358 new cases; 1700.8 new cases per 100 000; a 57% increase).

The highest number of new deaths were reported from the Russian Federation (5645 new deaths; 3.9 new deaths per 100 000; a 10% decrease), Poland (2150 new deaths; 5.7 new deaths per 100 000; a 34% decrease), and Germany (1822 new deaths; 2.2 new deaths per 100 000; similar to the previous week's figures).

Updates from the [European Region](#)

South-East Asia Region

During the past week, the South-East Asia Region reported over 699 000 new cases, a 418% increase, an incidence not seen since mid-August 2021. Seven countries (78%) reported large increases, of over 50%, with the highest increases reported from India, Timor-Leste (six vs 17 new cases; a 183% increase) and Bangladesh.). The highest numbers of new cases were reported from India (638 872 new cases; 46.3 new cases per 100 000; a 524% increase), Thailand (39 992 new cases; 57.3 new cases per 100 000; a 104% increase), and Bangladesh (7234 new cases; 4.4 new cases per 100 000; a 125% increase).

The number of deaths however, declined in the past week with over 2300 new deaths reported, a 6% decrease as compared to the previous week. The highest numbers of new deaths were reported from India (2020 new deaths; <1 new death per 100 000; similar to the previous week's figures), Thailand (105 new deaths; <1 new death per 100 000; a 25% decrease), and Sri Lanka (100 new deaths; <1 new death per 100 000; a 26% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The number of reported new cases in the Western Pacific Region more than doubled (122%) in the past week with over 732 000 new cases reported. Of the 27 countries in the Region, 10 (37%) reported an increase of over 50% in new cases this week with the highest increases reported from the Philippines, Japan (23 168 vs 2777 new cases, a 734% increase) and Guam (666 vs 92 new cases, a 624% increase). The highest numbers of new cases were reported from Australia (420 079 new cases; 1647.4 new cases per 100 000; a 204% increase), Viet Nam (130 302 new cases; 133.9 new cases per 100 000; a 19% increase), and the Philippines (89 409 new cases; 81.6 new cases per 100 000; an 880% increase).

Just over 2700 new deaths were reported this week, similar to the previous week's figures. The highest numbers of new deaths were reported from Viet Nam (1507 new deaths; 1.5 new deaths per 100 000; a 6% decrease), the Philippines (590 new deaths; <1 new death per 100 000; a 65% increase), and the Republic of Korea (343 new deaths; <1 new death per 100 000; a 24% decrease).

Annexes

Annex 1. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than four months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in the Table 3.

unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)

Annex 3. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 73, published 6 January 2022

In this edition:

- [Global overview](#)
- [WHO regional overviews](#)

Global overview

Data as of 2 January 2022

During the week 27 December 2021 to 2 January 2022, following a gradual increase since October, the global number of new cases increased sharply by 71% as compared to the previous week (Table 1), while the number of new deaths decreased by 10%. This corresponds to just under 9.5 million new cases and over 41 000 new deaths reported during the last week. As of 2 January, a total of nearly 289 million cases and just over 5.4 million deaths have been reported globally (Figure 1).

All regions reported an increase in the incidence of weekly cases, with the Region of the Americas reporting the largest increase (100%), followed by the South-East Asia (78%), European (65%), Eastern Mediterranean (40%), Western Pacific (38%) and the African (7%) Regions. The African Region was the only region to report a weekly increase in the number of new deaths (22%). All other regions reported a decrease in the incidence of deaths, including the Americas (18%), Western Pacific (10%), South-East Asia (9%), Eastern Mediterranean (7%) and the European (6%) Regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 2 January 2022**

**See [Annex 1: Data, table, and figure notes](#)

The European Region continued to report the highest incidence of weekly cases (577.7 new cases per 100 000 population), followed by the Region of the Americas (319.0 new cases per 100 000 population). Both regions also reported the highest weekly incidence in deaths of 2.4 and 1.1 per 100 000 population, respectively, while all other regions reported <1 new death per 100 000.

The highest numbers of new cases were reported from the United States of America (2 556 690 new cases; 92% increase), the United Kingdom (1 104 316 new cases; 51% increase), France (1 093 162 new cases; 117% increase); Spain (649 832 new cases; 60% increase) and Italy (644 508 new cases; 150% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 2 January 2022**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	5 390 588 (57%)	65%	103 190 471 (36%)	22 817 (55%)	-6%	1 674 758 (31%)
Americas	3 263 069 (34%)	100%	104 698 449 (36%)	10 787 (26%)	-18%	2 411 818 (44%)
Western Pacific	329 598 (3%)	38%	11 391 761 (4%)	2 769 (7%)	-10%	156 515 (3%)
Africa	294 373 (3%)	7%	7 350 001 (3%)	1 159 (3%)	22%	156 451 (3%)
South-East Asia	135 147 (1%)	78%	45 034 821 (16%)	2 454 (6%)	-9%	721 940 (13%)
Eastern Mediterranean	107 713 (1%)	40%	17 201 367 (6%)	1 192 (3%)	-7%	316 141 (6%)
Global	9 520 488 (100%)	71%	288 867 634 (100%)	41 178 (100%)	-10%	5 437 636 (100%)

African Region

The African Region reported over 294 000 new cases, with a similar increase in incidence as the previous week (7%). Increases in case incidence of over 50% as compared to the previous week were observed in over half of countries (28/49; 57%) in the Region. The highest numbers of new cases were reported from South Africa (60 142 new cases; 101.4 new cases per 100 000 population; a 48% decrease), Ethiopia (28 590 new cases; 24.9 new cases per 100 000 population; a 43% increase) and Mozambique (26 860 new cases; 85.9 new cases per 100 000; a 298% increase).

The Region reported over 1100 new weekly deaths, a 22% increase as compared to the number reported during the previous week. The highest numbers of new deaths were reported from South Africa (425 new deaths; <1 new death per 100 000 population; similar to the previous week), Zimbabwe (132 new deaths; <1 new death per 100 000; a 28% increase) and Algeria (55 new deaths; <1 new death per 100 000; an 12% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 3.2 million new cases, an increase of 100%, as compared to the previous week. The trends are largely driven by the incidence of cases in the United States of America and over 70% of the countries (39/56) reported increases of over 50%. The highest numbers of new cases were reported from the United States of America (2 556 690 new cases; 772.4 new cases per 100 000; a 92% increase), Argentina (229 192; 507.1 new cases per 100 000; a 290% increase) and Canada (180 587 new cases; 478.5 new cases per 100 000; a 90% increase).

Over 10 000 new deaths were reported, a 18% decrease as compared to the number reported during the previous week. The highest numbers of new deaths were reported from the United States of America (8004 new deaths; 2.4 new deaths per 100 000; a 22% decrease), Brazil (664 new deaths; <1 new death per 100 000; a 16% decrease), and Mexico (646 new deaths; <1 new death per 100 000; a 31% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

After reporting relatively stable number of weekly cases over the past two months, countries in the Eastern Mediterranean Region reported a 40% increase in the number of new weekly cases, with over 107 000 cases reported. Half of the countries (11/22) reported increases in cases of over 50%, with the highest increases reported from Morocco (9833 vs 2959 new cases, a 232% increase); Kuwait (2812 vs 888 new cases, a 217% increase) and Bahrain (3159 vs 1108 new cases, 185% increase). The highest numbers of new cases were reported from Lebanon (20 029 new cases; 293.4 new cases per 100 000; a 70% increase), the United Arab Emirates (14 963 new cases; 151.3 new cases per 100 000; a 164% increase) and Jordan (12 856 new cases; 126.0 new cases per 100 000; a 28% decrease).

The weekly incidence of deaths in the Region decreased by 7%, while the highest numbers of new deaths were reported from the Islamic Republic of Iran (291 new deaths; <1 new death per 100 000; an 8% decrease), Jordan (240 new deaths; 2.4 new deaths per 100 000; a 5% decrease) and Egypt (197 new deaths; <1 new death per 100 000; a 23% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported just under 5.4 million new cases, a 65% increase as compared to the previous week. The weekly incidence of deaths decreased by 6%, as compared to the previous week, with over 22 000 new deaths reported. Weekly increases in cases of over 50% were reported by 43% (26/61) of countries in the Region, with the highest increases reported from Montenegro (9093 vs 1299 new cases, a 353% increase), Greece (170 029 vs 39 594 new cases, a 329% increase) and Cyprus (19 311 vs 5135 new cases, a 276% increase). The highest numbers of new cases were reported from the United Kingdom (1 104 316 new cases; 1626.7 new cases per 100 000; a 51% increase), France (1 093 162 new cases; 1680.8 new cases per 100 000; a 117% increase) and Spain (649 832 new cases; 1372.9 new cases per 100 000; a 60% increase).

The highest numbers of new deaths continue to be reported from the Russian Federation (6300 new deaths; 4.3 new deaths per 100 000; a 10% decrease), Poland (3265 new deaths; 8.6 new deaths per 100 000; a 15% increase), and Germany (1791 new deaths; 2.2 new deaths per 100 000; a 16% decrease).

Updates from the [European Region](#)

South-East Asia Region

After a declining trend in the number of weekly cases since the end of July 2021, the South-East Asia Region reported an increase in case incidence of 78%, corresponding to over 135 000 new cases. However, the number of new weekly deaths decreased by 9%, with over 2400 new deaths reported. Half of the countries (5/10) reported weekly increases in the number of new cases of over 10%. After India, the highest increases in new cases were reported by Bangladesh (3213 vs 2170 new cases, a 48% increase) and the Maldives (1188 vs 907 new cases, a 31% increase). The highest numbers of new cases were reported from India (102 330 new cases; 7.4 new cases per 100 000; a 120% increase), Thailand (19 588 new cases; 28.1 new cases per 100 000; a 6% increase) and Sri Lanka (4286 new cases; 20.0 new cases per 100 000; an 8 increase).

The highest numbers of new deaths continued to be reported from India (2088 new deaths; <1 new death per 100 000; an 8% decrease), Thailand (140 new deaths; <1 new death per 100 000; a 31% decrease), and Sri Lanka (135 new deaths; <1 new death per 100 000; similar to the previous week).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 329 000 new cases, a 38% increase, as compared to the previous week. The incidence of deaths decreased by 10% as compared to the previous week, with over 2700 new weekly deaths reported. Nearly one-third of the countries in the Region (8/27, 30%) reported an increase in case incidence of over 50%, with the highest increases reported from the Philippines (9124 vs 833 new cases, a 995% increase), Fiji (1614 vs 192 new cases, a 741% increase) and Australia. The highest numbers of new cases were reported from Australia (138 240 new cases; 542.1 new cases per 100 000; a 203% decrease), Viet Nam (109 637 new cases; 112.6 new cases per 100 000, similar to the previous week), and the Republic of Korea (31 615 new cases; 61.7 new cases per 100 000; a 25% decrease).

The highest numbers of new deaths were reported from Viet Nam (1603 new deaths; 1.6 new deaths per 100 000; similar to the previous week), the Republic of Korea (449 new deaths; <1 new death per 100 000; a 14% decrease), and the Philippines (358 new deaths; <1 new death per 100 000; a 30% decrease).

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 72, published 28 December 2021

In this edition:

- [Global overview](#)
- [Brief Update on SARS-CoV-2 Omicron variant](#)
- [WHO regional overviews](#)

Global overview

Data as of 26 December 2021

During the week 20-26 December, following a gradual increase since October, the global number of new cases increased by 11% as compared to the previous week (Table 1); while the number of new deaths remained similar to the number reported during the previous week. This corresponds to just under 5 million new cases and over 44 000 new deaths. As of 26 December, over 278 million cases and just under 5.4 million deaths have been reported globally (Figure 1).

The Region of the Americas reported the largest increase in new cases in the last week (39%), followed by the African Region, which reported an increase of 7%. The South-East Asia Region continued to report a decrease in new cases as compared to the previous week (12%) while in the European, Eastern Mediterranean, and Western Pacific Regions, the number of new cases was similar to those reported during the previous week. The African Region reported the highest increase in the number of new deaths (72%), followed by the South-East Asia Region (9%) and the Region of the Americas (7%). The European and Eastern Mediterranean Region reported decreases of 12% and 7% respectively, in the incidence of deaths, while in the Western Pacific Region, the incidence was similar to the previous weeks.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 26 December 2021**

**See [Annex 1: Data, table, and figure notes](#)

The European Region continued to report the highest incidence of weekly cases (304.6 new cases per 100 000 population), followed by the Region of the Americas (144.4 new cases per 100 000 population). Both regions also reported the highest weekly incidence in deaths of 2.6 and 1.2 per 100 000 population, respectively, while all other regions reported <1 new death per 100 000.

The highest numbers of new cases were reported from the United States of America (1 185 653 new cases; 34% increase), the United Kingdom (611 864 new cases; 20% increase), France (504 642 new cases; 41% increase); Italy (257 579 new cases; 62% increase) and Germany (197 845 new cases; 30% decrease).

Please note, the next issue of the Weekly Epidemiological Update (to be published on 6 January) will be condensed versions covering only the global and regional epidemiology of COVID-19.

Brief Update on SARS-CoV-2 Omicron variant

The overall risk related to the new variant of concern Omicron remains very high. Consistent evidence shows that the Omicron variant has a growth advantage over the Delta variant with a doubling time of 2-3 days and rapid increases in the incidence of cases is seen in a number of countries, including those where the variant has become the dominant SARS-CoV-2 variant, such as the United Kingdom and the United States of America. However, a decline in the incidence of cases has now been observed in South Africa. The rapid growth rate is likely to be a combination of both immune evasion and intrinsic increased transmissibility of the Omicron variant. Early data from the United Kingdom, South Africa and Denmark suggests there is a reduced risk of hospitalization for the Omicron compared to the Delta variant, however, further data are needed to understand the clinical markers of severity including the use of oxygen, mechanical ventilation and death, and how severity may be impacted by vaccination and/or prior SARS-CoV-2 infection. It is also expected that corticosteroids and interleukin 6 receptor blockers will remain effective in the management of patients with severe disease, however, preliminary data suggest that monoclonal antibodies may be less able to neutralize the Omicron variant. Reassuringly, preliminary data suggests testing using either PCR or antigen-based rapid diagnostic tests (Ag-RDT) assays does not appear to be impacted by the Omicron variant. More information on this variant can be found in the updated [Technical Brief and Priority Actions for Member States](#) that was published on 23 December 2021 by WHO.

African Region

The African Region reported over 274 000 new cases, however, the weekly increase in incidence was smaller (7%) as compared to the incidence of the previous week (53%). Increases in case incidence of over 50% were observed in nearly two-thirds (32/49; 65%) of countries in the Region. The highest numbers of new cases were reported from South Africa (115 328 new cases; 194.5 new cases per 100 000 population; a 29% decrease), Ethiopia (19 940 new cases; 17.3 new cases per 100 000 population; a 610% increase) and Kenya (19 023 new cases; 35.4 new cases per 100 000; a 207% increase).

The Region reported over 900 new weekly deaths, a 72% increase as compared to the number reported during the previous week. The highest numbers of new deaths were reported from South Africa (428 new deaths; <1 new death per 100 000 population; an 87% increase), Zimbabwe (103 new deaths; <1 new death per 100 000; a 119% increase) and the Democratic Republic of the Congo (79 new deaths; <1 new death per 100 000; an 888% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.4 million new cases and over 12 000 new deaths, increases of 39% and 7% respectively, as compared to the previous week. Half of the countries (28/56) reported increases of over 10%, with the highest increases reported from Saint Kitts and Nevis (38 vs 3 new cases, an 1167% increase albeit small numbers); the United States Virgin Islands (367 vs 42 new cases, a 774% increase) and Puerto Rico (32 162 vs 3736 new cases, a 761% increase). However, the highest numbers of new cases continued to be reported from the United States of America (1 185 653 new cases; 358.2 new cases per 100 000; a 34% increase), Canada (78 847 new cases; 208.9 new cases per 100 000; a 101% increase), and Argentina (65 966 new cases; 146.0 new cases per 100 000; a 106% increase).

The highest numbers of new deaths were reported from the United States of America (9355 new deaths; 2.8 new deaths per 100 000; a 7% increase), Brazil (997 new deaths; <1 new death per 100 000; a 42% increase), and Mexico (797 new deaths; <1 new death per 100 000; a 41% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The weekly incidence of cases in the Eastern Mediterranean Region remained similar to the incidence reported during the previous week, with over 76 000 new cases reported. Half of the countries (11/22) reported increases in cases of over 10%, with the highest increases reported from the United Arab Emirates (5678 vs 1133 new cases, a 401% increase); Somalia (363 vs 95 new cases, a 282% increase) and Saudi Arabia (1668 vs 549 new cases, 204% increase). The highest numbers of new cases continued to be reported from Jordan (17 952 new cases; 267.9 new cases per 100 000; a 34% decrease), the Islamic Republic of Iran (13 894 new cases; 16.5 new cases per 100 000; a 16% decrease), and Lebanon (11 795 new cases; 172.8 new cases per 100 000; an 8% increase).

The weekly incidence of deaths in the Region decreased by 7%, while the highest numbers of new deaths continued to be reported from the Islamic Republic of Iran (315 new deaths; <1 new death per 100 000; a 15% decrease), Egypt (256 new deaths; <1 new death per 100 000; a 15% decrease), and Jordan (253 new deaths; 2.5 new deaths per 100 000; similar to the previous week).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 2.8 million new cases, similar to the number reported during the previous week. However, the weekly incidence of deaths decreased by 12%, with over 24 000 new deaths reported. Despite the stable trend, one third of countries (20/61) reported a weekly increase in cases of over 10%, with the highest increases reported from Malta (4107 vs 1103 new cases, an 272% increase), Israel (9076 vs 4886 new cases, an 86% increase) and Portugal (55 217 vs 30427 new cases, an 81% increase). The highest numbers of new cases were reported from the United Kingdom (611 864 new cases; 901.3 new cases per 100 000; a 20% increase), France (504 642 new cases; 775.9 new cases per 100 000; a 41% increase) and Italy (257 579 new cases; 431.9 new cases per 100 000; a 62% increase).

The highest numbers of new deaths continued to be reported from the Russian Federation (7015 new deaths; 4.8 new deaths per 100 000; a 9% decrease), Poland (2842 new deaths; 7.5 new deaths per 100 000; a 5% decrease), and Germany (2131 new deaths; 2.6 new deaths per 100 000; an 18% decrease).

Updates from the [European Region](#)

South-East Asia Region

The declining trend in the number of weekly cases reported has continued in the South-East Asia Region, with over 76 000 new cases reported, a 12% decrease as compared to the number reported during the previous week. However, the number of new weekly deaths increased by 9%, with 2700 new deaths reported. Only two countries in the Region reported an increase in weekly cases: Bangladesh (2170 vs 310 new cases, a 23% increase) and the Maldives (907 vs 838 new cases, an 8% increase). However, the highest numbers of new cases continued to be reported from India (46 527 new cases; 3.4 new cases per 100 000; a 7% decrease), Thailand (18 442 new cases; 26.4 new cases per 100 000; a 19% decrease), and Sri Lanka (3964 new cases; 18.5 new cases per 100 000; a 42% decrease).

The highest numbers of new deaths also continued to be reported from India (2260 new deaths; <1 new death per 100 000; a 14% increase), Thailand (203 new deaths; <1 new death per 100 000; similar to the previous week), and Sri Lanka (132 new deaths; <1 new death per 100 000; similar to the previous week).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The incidence of cases and deaths reported in the Western Pacific Region was similar to those reported during the previous week, with over 238 000 new cases and over 3000 new deaths reported. However, seven of the 27 countries in the region, reported an increase in case incidence of over 10%, with the highest increases reported from French Polynesia (40 vs 8 new cases, a 400% increase), Fiji (192 vs 39 new cases, a 392% increase) and Australia. The highest numbers of new cases were reported from Viet Nam (112 087 new cases; 115.2 new cases per 100 000; a 11% decrease), Australia (45 560 new cases; 178.7 new cases per 100 000, a 135% increase), and the Republic of Korea (42 367 new cases; 82.6 new cases per 100 000; an 11% decrease).

The highest numbers of new deaths were reported from Viet Nam (1656 new deaths; 1.7 new deaths per 100 000; similar to the previous week), the Republic of Korea (523 new deaths; 1.0 new death per 100 000; a 12% increase), and the Philippines (512 new deaths; <1 new death per 100 000; a 12% decrease).

Annex 1. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 cases and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 71, published 21 December 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 19 December 2021

During the week 13-19 December, the global number of new cases remained similar to those reported during the previous week (Table 1); however, the weekly incidence of deaths decreased by 9%. Nonetheless, this corresponds to over 4.1 million new cases and just under 45 000 new deaths. As of 19 December, over 273 million cases and over 5.3 million deaths have been reported globally (Figure 1).

The African Region continued to report the largest increase in new cases in the last week (53%), followed by the Western Pacific Region, which reported an increase of 12%. The South-East Asia and the Eastern Mediterranean regions both reported decreases of 12% and the Region of the Americas reported a 10% decrease. The number of new weekly cases reported by the European Region was similar to the numbers reported in the previous week. The African Region was the only region to report an increase in the number of new weekly deaths (15%). The Region of the Americas reported the largest decrease (15%), followed by the Eastern Mediterranean Region (12%), the European Region (7%) and the Western Pacific and South-East Asia Regions (both 6%).

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 19 December 2021**

**See [Annex 2: Data, table, and figure notes](#)

The European Region continued to report the highest incidence of weekly cases (279.9 new cases per 100 000 population), followed by the Region of the Americas (88.5 new cases per 100 000 population). Both regions also reported the highest weekly incidence in deaths of 2.9 and 1.0 per 100 000 population, respectively, while all other regions reported <1 new death per 100 000.

The highest numbers of new cases were reported from the United States of America (725 750 new cases; 12% decrease), the United Kingdom (507 984 new cases; 45% increase), France (358 175 new cases; 7% increase) and Germany (283 673 new cases; 19% decrease).

Please note, the next two issues of the Weekly Epidemiological Report (to be published on 28 December and 6 January) will be condensed versions covering only the global and regional epidemiology.

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 19 December 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 611 478 (63%)	-3%	94 345 936 (35%)	26 802 (60%)	-7%	1 626 294 (30%)
Americas	904 789 (22%)	-10%	99 606 828 (36%)	10 255 (23%)	-15%	2 384 550 (45%)
Africa	256 031 (6%)	53%	6 778 548 (2%)	564 (1%)	15%	154 330 (3%)
Western Pacific	239 159 (6%)	12%	10 823 510 (4%)	3 144 (7%)	-6%	150 683 (3%)
South-East Asia	86 545 (2%)	-12%	44 823 551 (16%)	2 475 (6%)	-6%	716 778 (13%)

Special Focus: Update on SARS-CoV-2 variants of interest and variants of concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Potential variants of concern (VOCs), variants of interest (VOIs) or variants under monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, a declining trend in the proportion of Alpha, Beta and Gamma variants, which have been circulating at a very low prevalence for several weeks, and the emergence of Omicron variant (Figure 4; Annex 1). Following the classification of Omicron as a VOC, many countries have adopted targeted sequencing strategies to detect the variant. The change in sampling strategy, away from community-based surveillance sequencing, may result in biases in the proportions of variants being reported. Thus, the recent declines in the proportion of Delta variant reported by some countries may reflect changes in sampling strategy, rather than declines in the proportion of Delta variant cases among all COVID-19 cases.

While most of the Omicron cases identified in November 2021 were travel-related, community transmission with associated clusters has now been reported in several countries. Of 1 051 598 sequencesⁱ, 1 009 253 (96%) were Delta, 16 988 (1.6%) were Omicron, 176 (<0.1%) were Gamma, 53 (<0.1%) were Alpha, 16 (<0.1%) were Beta and 188 (<0.1%) comprised other circulating variants (including VOIs Mu and Lambda). To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Since the last [update published on 14 December](#), additional countries across all six WHO Regions have reported confirmed cases of the Omicron variant. As of 21 December 2021 (2 pm CET), the Omicron variant has been confirmed in 106 countries.

Recent evidence indicates that Omicron variant has a growth advantage over the Delta variant and is spreading rapidly, even in countries with documented community transmission and high levels of population immunity. It remains uncertain to what extent the observed rapid growth rate can be attributed to immune evasion, intrinsic increased transmissibility, or a combination of both. There are still limited data on the clinical severity of Omicron. Hospitalizations in the UK and South Africa continue to rise, and given rapidly increasing case numbers, it is possible that healthcare systems may become overwhelmed. Preliminary data suggest that there is a reduction in neutralization of Omicron in those who have received a primary vaccination series or in those who have had prior SARS-CoV-2 infection, which may suggest a level of humoral immune evasion.

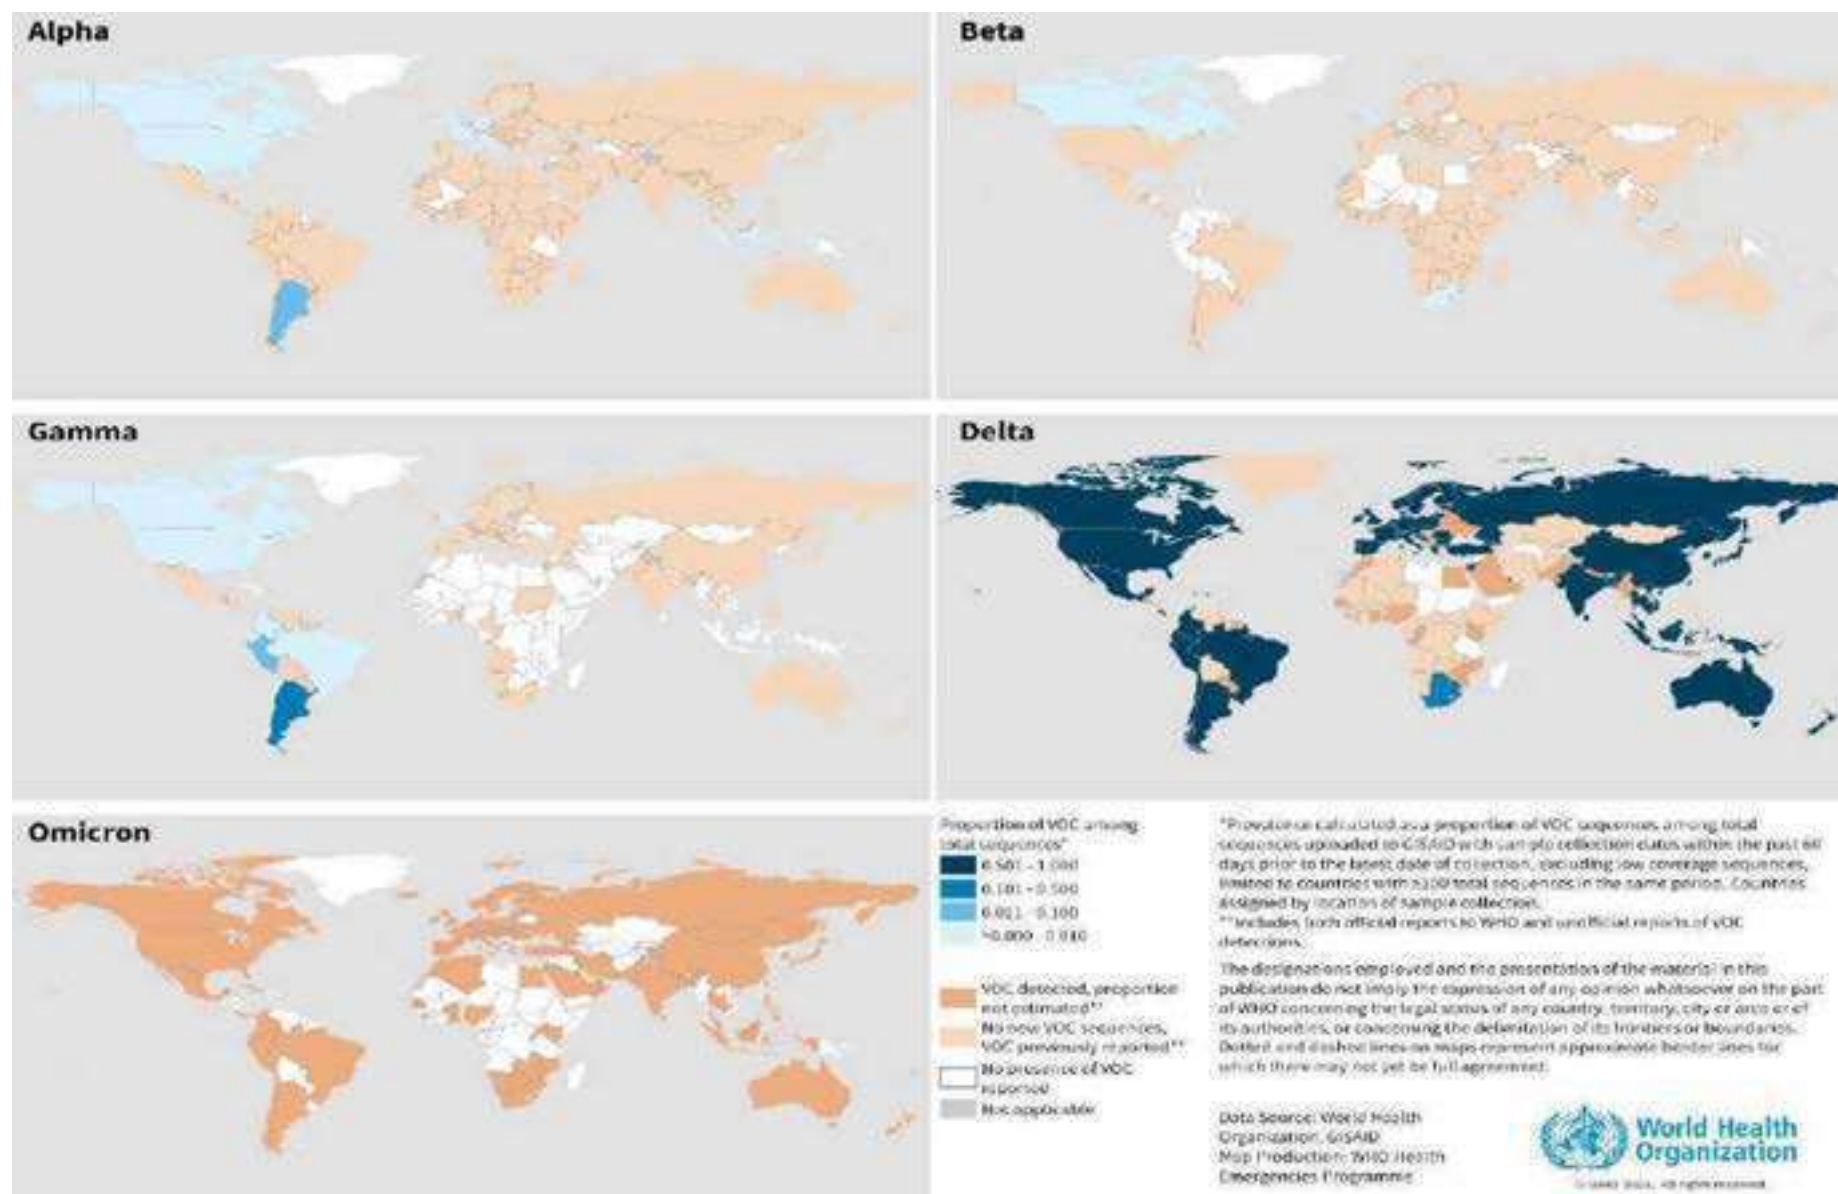

As a result of this, the overall risk related to the new variant of concern Omicron remains very high. More information on this variant can be found in the updated [Technical Brief and Priority Actions for Member States](#) that was published on 17 December 2021 by WHO.

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 20 October to 19 December 2021 (last reported sample at the time of data extraction), excluding low coverage sequences.

Figure 4: Presence and prevalence of variants of concern (VOCs) in the last 60 days and historic detections, data as of 21 December 2021

See also [Annex 1](#) for reported VOC detections by country/territory/area and the verification status.

African Region

The African Region continued to see an increase in the reported case incidence in the last month. Over 256 000 new cases were reported (an increase of 53%) as compared to the previous week, the highest number of weekly cases reported since the start of the pandemic. Increases in incidence of over 50% were observed in nearly half (23/49; 47%) of countries in the Region. The highest numbers of new cases continued to be reported from South Africa (162 987 new cases; 274.8 new cases per 100 000 population; a 50% increase) and Zimbabwe (26 671 new cases; 179.4 new cases per 100 000 population; similar to the previous week's number), with Eswatini now reporting the third highest incidence of cases (7540 new cases; 649.9 new cases per 100 000 population; a 57% increase).

The Region reported just under 500 new weekly deaths, similar to the number in the previous week. The highest numbers of new deaths were reported from South Africa (229 new deaths; <1 new death per 100 000 population; a 52% increase), Mauritius (60 new deaths; 4.7 new deaths per 100 000; a 35% decrease), and Zimbabwe (47 new deaths; <1 new death per 100 000; an 81% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 904 000 new cases and over 10 000 new deaths, decreases of 10% and 15% respectively as compared to the previous week. However, a quarter of the countries (14/56) reported increases of over 10%, with Puerto Rico reporting the highest increase (3736 new cases, a 425% increase). The highest numbers of new cases were reported from the United States of America (725 750 new cases; 219.3 new cases per 100 000; a 12% decrease), Canada (39 216 new cases; 103.9 new cases per 100 000; a 55% increase), and Argentina (32 013 new cases; 70.8 new cases per 100 000; a 91% increase).

The highest numbers of new deaths were reported from the United States of America (6723 new deaths; 2.0 new deaths per 100 000; a 20% decrease), Mexico (892 new deaths; <1 new death per 100 000; a 49% increase), and Brazil (704 new deaths; <1 new death per 100 000; a 45% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The weekly incidence of cases and deaths in the Eastern Mediterranean Region both decreased by 12%, with over 79 000 new cases and over 1300 new deaths reported. However, the percentage of countries reporting increases of over 10% rose from 13% to 45% (10/22 countries), with the highest increases reported from Somalia (95 vs 23 new cases, a 313% increase); the United Arab Emirates (1133 vs 441 new cases, a 157% increase) and Djibouti, although case numbers remain low (14 vs 6 new cases; a 133% increase). The highest numbers of new cases were reported from Jordan (27 333 new cases; 267.9 new cases per 100 000; an 21% decrease), the Islamic Republic of Iran (16 487 new cases; 19.6 new cases per 100 000; a 22% decrease), and Lebanon (10 949 new cases; 160.4 new cases per 100 000; a 3% decrease).

The highest numbers of new deaths continued to be reported from the Islamic Republic of Iran (372 new deaths; <1 new death per 100 000; a 31% decrease), Egypt (300 new deaths; <1 new death per 100 000; a 10% decrease), and Jordan (250 new deaths; 2.5 new deaths per 100 000; an 11% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 2.6 million new cases, similar to the previous week's number. However, the weekly incidence of deaths decreased by 7%, with over 26 000 new deaths reported. Despite the stable trend, 20% of countries (12/61) still reported an increase of over 10% in cases as compared to the previous week, with the highest increases reported from Malta (1103 vs 603 new cases, an 83% increase) and Gibraltar (270 vs 148 new cases, an 82% increase). The highest numbers of new cases were reported from the United Kingdom (507 984 new cases; 748.3 new cases per 100 000; a 45% increase), France (358 175 new cases; 550.7 new cases per 100 000; a 7% increase) and Germany (283 673 new cases; 341.1 new cases per 100 000; a 19% decrease).

The highest numbers of new deaths were reported from the Russian Federation (7720 new deaths; 5.3 new deaths per 100 000; a 6% decrease), Poland (3006 new deaths; 7.9 new deaths per 100 000; a 7% increase), and Germany (2595 new deaths; 3.1 new deaths per 100 000; similar to the previous week).

Updates from the [European Region](#)

South-East Asia Region

The declining trend in the number of weekly cases and deaths reported has continued in the South-East Asia Region. Over 86 000 new cases and over 2400 new deaths were reported, decreases of 12% and 6% , respectively as compared to the previous week. Only two countries reported an increase in weekly cases, Timor Leste (4 vs 1 new case, a 300% increase) and Sri Lanka. The highest numbers of new cases continued to be reported from India (49 765 new cases; 3.6 new cases per 100 000; a 13% decrease), Thailand (22 882 new cases; 32.8 new cases per 100 000; a 17% decrease), and Sri Lanka (6783 new cases; 31.7 new cases per 100 000; a 30% increase).

The highest numbers of new deaths also continued to be reported from India (1988 new deaths; <1 new death per 100 000; a 6% decrease), Thailand (206 new deaths; <1 new death per 100 000; a 9% decrease), and Sri Lanka (138 new deaths; <1 new death per 100 000; a 10% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region continues to see an increase in the incidence of cases with 239 000 new cases reported during the previous week (a 12% increase). Three of the 27 countries in the region, reported an increase in case incidence of over 10% including: Australia (19 415 vs 10 805 new cases, a 80% increase), Japan (1088 vs 861 new cases, a 26% increase) and Viet Nam. The highest numbers of new cases were reported from Viet Nam (125 955 new cases; 129.4 new cases per 100 000; a 22% increase), the Republic of Korea (47 825 new cases; 93.3 new cases per 100 000; an 8% increase), and Malaysia (27 698 new cases; 85.6 new cases per 100 000; an 18% decrease).

The incidence of deaths decreased by 6% as compared to the previous week, with over 3100 new deaths reported. The highest numbers of new deaths continued to be reported from Viet Nam (1740 new deaths; 1.8 new deaths per 100 000; a 12% increase), the Philippines (579 new deaths; <1 new death per 100 000; a 33% decrease), and the Republic of Korea (469 new deaths; <1 new death per 100 000; a 17% increase).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 21 December, highlights include the following:

- Implementing national studies on the real-world effectiveness of COVID-19 vaccines in Armenia
- Delivering critical equipment and supplies in the Western Pacific to Vanuatu and Fiji
- Boosting Sierra Leone's COVID-19 response and disease surveillance with laboratory commodities
- Bringing COVID-19 vaccination to the most vulnerable via the Global Health Cluster
- Supporting the global scale-up of infodemic management
- Strengthening genomic surveillance: WHO in collaboration with GISAID organizes training workshops for laboratory experts
- Conducting the first Universal Health and Preparedness Review (UHPR) Pilot: Bangui, Central African Republic
- Updates on WHO's financing to support countries on COVID-19 response implementation to suppress transmission, reduce exposure, and protect the vulnerable and save lives
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

*r this variant was received by WHO from unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)*

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 70, published 14 December 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 12 December 2021

Globally, the weekly incidence of both cases and deaths declined during the past week (6-12 December 2021), with decreases of 5% and 10% respectively, as compared to the previous week. Nonetheless, this still corresponded to over 4 million new confirmed cases and just under 47 000 new deaths. As of 12 December, nearly 269 million confirmed cases and nearly 5.3 million deaths have been reported globally.

The African Region reported the largest increase in new cases last week (111%) followed by the Western Pacific Region which reported an increase of 7%. The Region of the Americas and South-East Asia Region both reported decreases of 10% and the European Region reported a 7% decrease. The number of new weekly cases reported by the Eastern Mediterranean Region was similar to the numbers reported in the previous week. New weekly deaths decreased by 50% in the South-East Asia Region (due to an artificial increase in deaths from batch reporting in the previous week) and 14% in the Region of the Americas, while the number of weekly deaths in all other regions remained similar to those reported in the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 12 December 2021**

**See [Annex 3: Data, table, and figure notes](#)

The regions reporting the highest weekly case incidence per 100 000 population continue to be the European Region (277.9 new cases per 100 000 population) and the Region of the Americas (81.9 new cases per 100 000 population). Both regions also reported the highest weekly incidence in deaths of 3.0 and 1.0 per 100 000 population, respectively while <1 new death per 100 000 was reported in all other regions.

The highest numbers of new cases were reported from the United States of America (674 019 new cases; 9% decrease), Germany (351 738 new cases; 11% decrease), the United Kingdom (350 340 new cases; 13% increase), France (335 972 new cases; 19% increase), and the Russian Federation (215 283 new cases; 7% decrease).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 12 December 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 593 221 (65%)	-7%	91 631 852 (34%)	28 362 (60%)	-3%	1 598 688 (30%)
Americas	837 345 (21%)	-10%	98 521 311 (37%)	10 562 (22%)	-14%	2 371 246 (45%)
Western Pacific	213 915 (5%)	7%	10 584 344 (4%)	3 335 (7%)	4%	147 539 (3%)
Africa	167 682 (4%)	111%	6 522 517 (2%)	491 (1%)	-1%	153 766 (3%)
South-East Asia	98 021 (2%)	-10%	44 737 006 (17%)	2 643 (6%)	-50%	714 303 (13%)
Eastern Mediterranean	90 633 (2%)	-4%	16 936 781 (6%)	1 568 (3%)	-3%	312 295 (6%)
Global	4 000 817 (100%)	-5%	268 934 575 (100%)	46 961 (100%)	-10%	5 297 850 (100%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Potential Variants of Concern (VOCs), Variants of Interest (VOIs) or Variants Under Monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

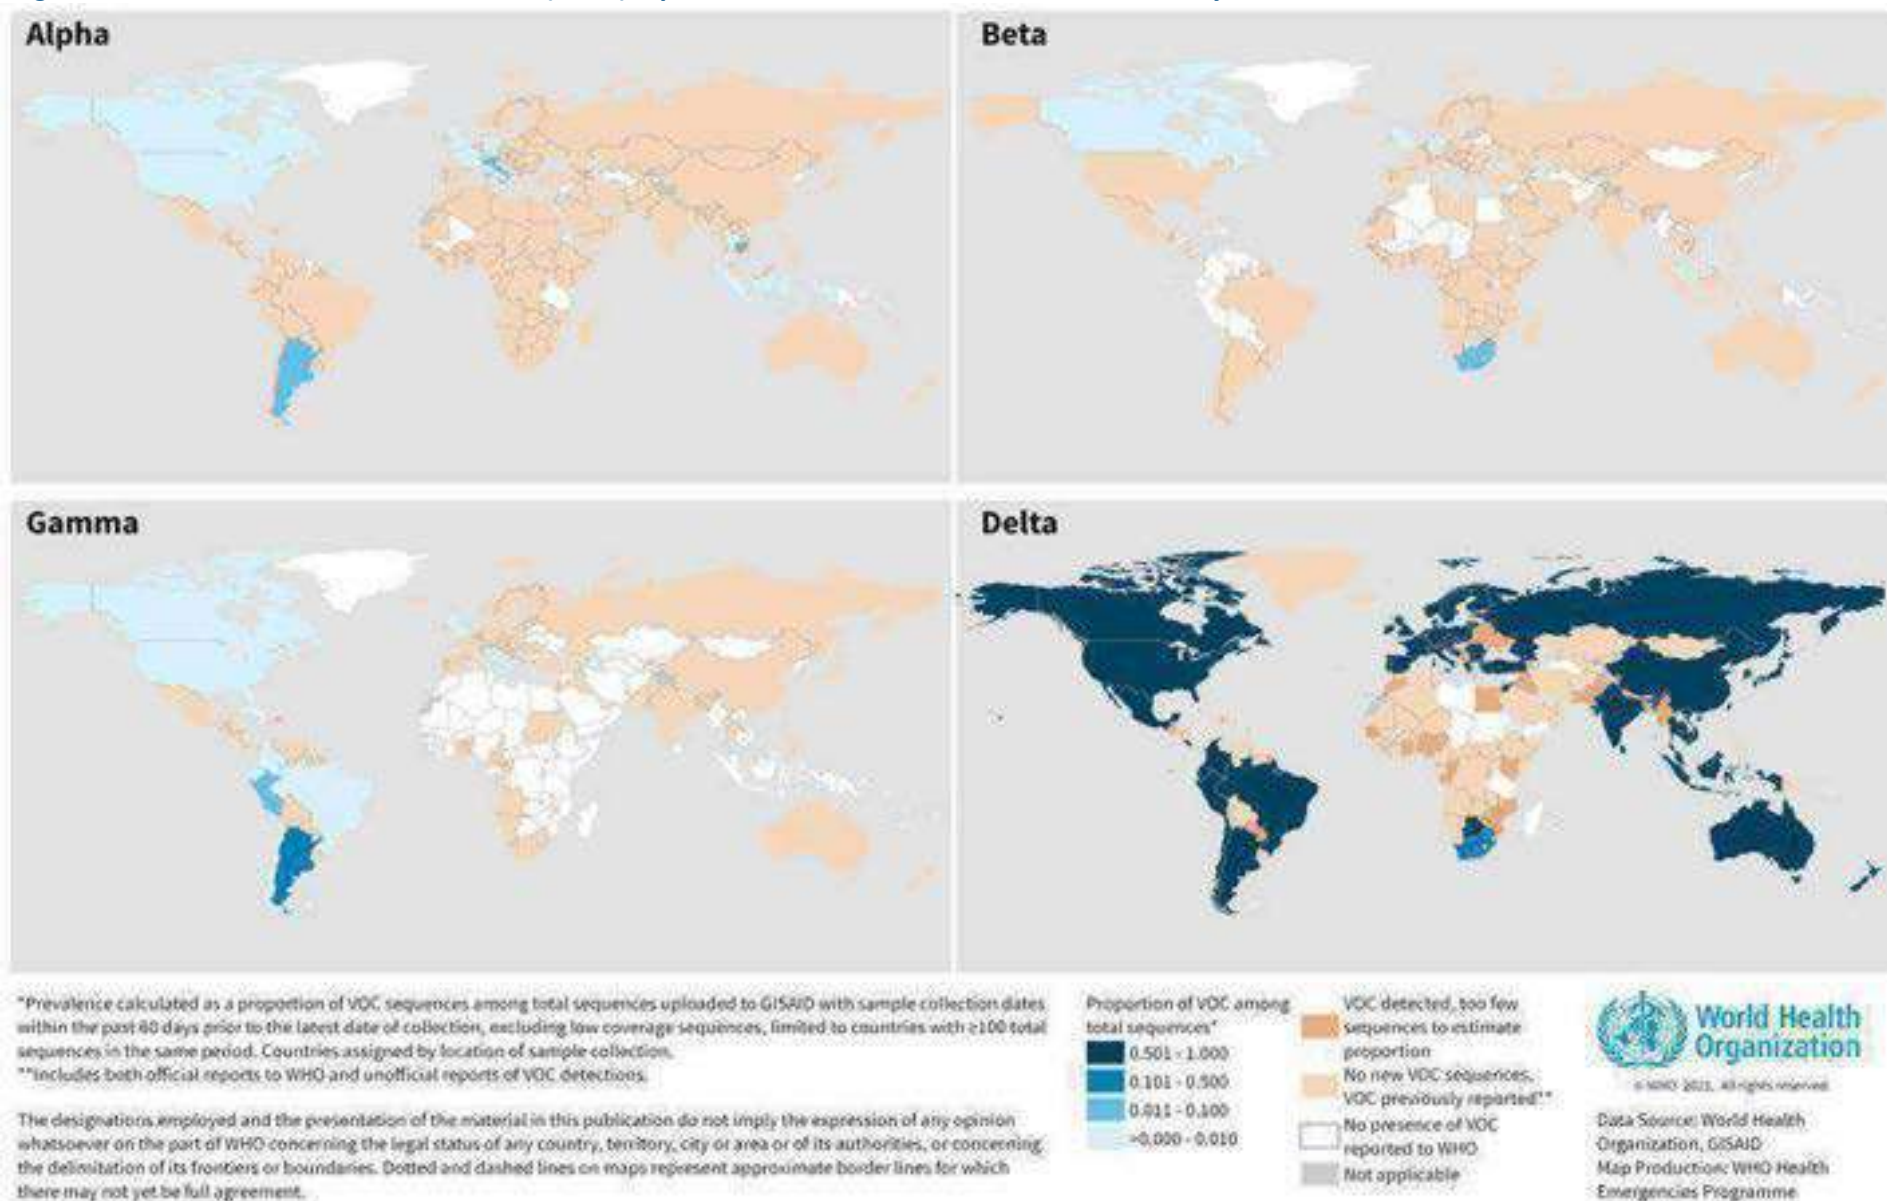

The current global epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, declining trend in the proportion of Alpha, Beta and Gamma, and the emergence of Omicron variant; however, regional and country-level variations continue to be observed (Figure 4 and 5; Annex 2). While most of the Omicron cases identified in November 2021 were travel-related, community transmission with associated clusters has now been reported in several countries. Of 879 779 sequences uploaded to GISAID with specimens collected in the last 60 days, 872 876 (99.2%) were Delta, 3 755 (0.4%) were Omicron, 206 (<0.1%) Alpha, 179 (<0.1%) Gamma, 16 (<0.1%) Beta, and <0.1% comprised other circulating variants (including VOIs Mu and Lambda). This week, for the first time since Delta was classified as a VOC in April 2021, the percentage of Delta sequences has declined in respect to other VOCs. However, this observation needs to be interpreted with caution as countries may perform targeted sequencing for Omicron and therefore upload fewer sequences on all other variants, including Delta.

To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Figure 4: Prevalence of Variants of Concern (VOCs) Alpha, Beta, Gamma and Delta in the last 60 days and historic detections, data as of 14 December 2021

See also [Annex 2](#) for reported VOC detections by country/territory/area

Figure 5. Presence of Variant of Concern (VOC) Omicron, data as of 14 December 2021 (4 pm CET)

Presence of the Omicron variant is based on information reported to WHO. It includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). See also [Annex 2](#) for reported VOC detections by country/territory/area.

Update on Omicron VOC

Since the last [update published on 7 December](#), additional countries across all six WHO Regions have reported confirmed cases of the Omicron variant. As of 14 December 2021 (2 pm CET), the Omicron variant has been confirmed in 76 countries.

Based on current limited evidence Omicron appears to have a growth advantage over Delta. It is spreading faster than the Delta variant in South Africa where Delta circulation was low, but also appears to be spreading more quickly than the Delta variant in countries where the incidence of Delta is high, such as in the United Kingdom.

The data on the clinical severity of Omicron remains limited. More information on case severity associated with Omicron is expected in the coming weeks due to the time lag between an increase in the incidence of cases and an increase in the incidence of severe cases, and deaths.

Preliminary evidence suggests that there may be a reduction in vaccine efficacy and effectiveness against infection and transmission associated with Omicron, as well as an increased risk of reinfection. More data are needed to better understand the extent to which Omicron may evade vaccine and/or infection derived immunity and the extent to which current vaccines continue to protect against severe disease and death associated with Omicron.

Diagnostic accuracy of routinely used PCR and antigen-based rapid diagnostic test (Ag-RDT) assays does not appear to be impacted by Omicron, and therapeutic interventions for the management of patients with severe or critical COVID-19 associated with the Omicron variant are expected to remain effective.

As a result of this, the overall risk related to the new variant of concern Omicron remains very high. More information on Omicron variant can be found in the updated [Technical Brief and Priority Actions for Member States](#) that was published on 10 December 2021 by WHO.

Phenotypic characteristics

Available evidence on the phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last detailed update on 30 November](#), there are several new publications on the phenotypic characteristics of VOCs, including recent literature on Omicron. Reported studies might have not been formally peer-reviewed and findings must be interpreted in the light of this limitation.

A cohort analysis reported by UK Health Security Agency¹, estimated the odds of household transmission for Omicron variant index cases as compared with Delta variant index cases. The analysis included 72,761 index cases of Delta and 121 of Omicron in residential households with a specimen collection date between 15 and 28 November 2021. Household transmission was defined as an index (first) case followed by one or more laboratory confirmed SARS-CoV-2 cases at the same private dwelling within a 14-day period (minimum 7 days follow-up). Multivariable logistic regression model found the adjusted odds ratio for household transmission from an Omicron index case was 3.2 (95%CI 2.0-5.0, $p < 0.001$) compared to Delta index cases.

Reports describing Omicron cases among partially and fully vaccinated individuals have been recently released:

- The US CDC² reported the characteristics of the 43 investigated cases attributed to the Omicron variant. Twenty-five of them (58%) were in persons aged 18–39 years, and 14 (33%) persons reported international travel during

the 14 days preceding symptom onset or receipt of a positive test result. Thirty-four cases (79%) occurred in persons who completed the primary series of an FDA-authorized or approved COVID-19 vaccine ≥ 14 days before symptom onset or receipt of a positive SARS-CoV-2 test result, including 14 who had received an additional or booster dose; five of the 14 persons had received the additional dose < 14 days before symptom onset. Six (14%) persons also had a documented previous SARS-CoV-2 infection. The most commonly reported symptoms were cough, fatigue, and congestion or runny nose. One vaccinated patient was hospitalized for 2 days, and no deaths among the 43 cases reported by US CDC have been reported to date. Case investigations have identified exposures associated with international and domestic travel, large public events, and household transmission.

- Preliminary findings published by the Norwegian Institute of Public Health (NIPH)³, described the result of the investigation of an Omicron outbreak that occurred during a Christmas party. Of 111 participants at the Christmas party, 73% (80 people) were subsequently diagnosed with SARS-CoV-2. Of these, 17 were confirmed with the Omicron variant by sequencing as of 8 December 2021. Analysis of additional samples is ongoing. Over 70% of cases reported cough, lethargy, headache, sore throat and over half of them reported fever. No hospital admissions have been reported. According to NIPH, most of the cases (the report does not specify the number) were aged between 30 and 50 years and were vaccinated with two doses of an mRNA vaccine between May and November 2021.
- A report from South Africa⁴ described seven cases of breakthrough infection with the Omicron variant among visitors who received three doses of SARS-CoV-2 vaccines. On arrival in South Africa during the first half of November, all cases provided a negative SARS-CoV-2 PCR test and a record of complete vaccination including the third dose. Six cases were fully vaccinated with Pfizer BioNTech-Comirnaty and five of them also received a third dose of the same vaccine in October or early November 2021. One person received a third dose of Moderna-mRNA-1273 at the beginning of October. The seventh subject received an initial dose of AstraZeneca-Vaxzevria, followed by two doses of Pfizer BioNTech-Comirnaty for completion of primary immunization and as a third dose. None of them had a previous history of a SARS-CoV-2 infection. The cases developed onset of mild respiratory symptoms from 30 November to 2 December 2021 while in Cape Town and samples were collected between 2 to 4 days after onset of symptoms. Genome sequencing confirmed 5 of the cases to be due to Omicron variant; in two cases sequencing failed but they are inferred to be Omicron, too, based on their very close epidemiological links to the others.

Preliminary evidence shows that sera obtained from vaccinated and previously infected individuals has lower neutralization activity on Omicron VOC than with any other circulating VOCs of SARS-CoV-2 and the ancestral strain:

- A study (not yet peer reviewed) conducted in South Africa⁵, investigated whether the Omicron variant escapes antibody neutralization elicited by the Pfizer BioNTech-Comirnaty vaccine. Plasma samples from 12 participants fully vaccinated were tested. Six participants had a record of previous infection from the first SARS-CoV-2 wave in South Africa that was due to the ancestral SARS-Cov-2 strain. The other six participants had no previous record of SARS-CoV-2 infection nor detectable nucleocapsid antibodies indicative of previous infection. Overall, the geometric mean titer 50% focus reduction neutralization test (GMT FRNT50) was 1321 for the ancestral strain, indicating a very strong neutralization. However, the GMT FRNT50 for the Omicron variant was 32, a 41-fold reduction compared to the ancestral strain. Those participants who had a previous infection in addition to vaccination, had a higher GMT FRNT50, both versus Omicron variant and the ancestral strain.
- Another preprint study⁶ analysed titers of neutralizing antibodies of sera from convalescent or vaccinated individuals against Omicron and compared them with titers against other VOCs (Alpha, Beta and Delta). Sera were selected from patients after an infection with Alpha (n=10), Beta (n=8) and Delta variants (n=7); from individuals

fully vaccinated with no previous SARS-CoV-2 infection (n=60) and fully vaccinated with previous SARS-CoV-2 infection (n=10). Sera from fully vaccinated individuals without previous SARS-CoV-2 infection neutralized the Omicron variant to a much lesser extent (not specified by authors) than any other VOCs analysed. Sera from fully vaccinated persons with previous SARS-CoV-2 infection, were able to neutralize Omicron variant, although to a lesser degree (not specified by authors) than the other VOCs.

- A study from Karolinska Institute⁷ (not yet published) assessed neutralization activity against the Omicron variant. Two cohorts with laboratory confirmed SARS-CoV-2 in May 2020 and serum samples collected in November 2021, were included. Cohort 1 comprised serum samples with detectable neutralization against the ancestral SARS-CoV-2 strain from 17 anonymized blood donors. Cohort 2 comprised 17 serum samples from hospital workers with previous SARS-Cov-2 infection and that were fully vaccinated (the report does not specify with which vaccine) . Almost all serum samples evaluated, retained some neutralization activity against the Omicron variant. Fold-reduction in the neutralization of Omicron relative to the ancestral strain, ranged from 1 to 23, with quartiles of 2.5, 5.5, and 11, measured by lentiviral pseudotype neutralization assay. As compared with Delta, Omicron showed a further reduction in neutralization activity, but that was not significant.

If specific antibodies neutralizing activity seems to be reduced versus the Omicron VOC, preliminary studies suggest that CD8+ T-cell responses may still maintain capability to recognize the Omicron VOC. A study from United States⁸ not yet published, examined SARS-CoV-2 CD8+ T-cell responses from 30 recovered COVID-19 convalescent patients, evaluating if the previously identified viral epitopes targeted by CD8+ T-cells in these individuals (n=52 distinct epitopes) are mutated in the newly described Omicron variant. Within this population, only one low-prevalence (found in 2/30 (7%) of participants) epitope restricted to two HLA alleles from the Spike protein was found to be mutated in Omicron and contains only a single amino acid change. These data suggest that individuals with existing anti-SARS-CoV-2 CD8+ T-cell responses should recognize the Omicron variant, and that SARS-CoV-2 has not evolved extensive T-cell escape mutations.

A retrospective cohort study⁹ was conducted in the United States to evaluate the duration of immunity to the Delta variant following infection. Of the samples tested prior from 9 March-31 December 2020, 15.5% (50 327/ 325 157) individuals were positive for SARS-CoV-2. During the Delta dominant period, protection of prior SARS-CoV-2 infection (defined as 1 minus the ratio of the infection rate for those initially positive to those initially negative) against reinfection was 85.4% (95%CI 80.0-89.3%) however, was lower for asymptomatic compared to symptomatic infection (66.6% (95%CI 40.6-81.2%). From 30 August 2020 to 9 September 2021, prior infection provided an overall 85.7% (95%CI 82.2-88.5%) protection against reinfection and again, protection against asymptomatic infection was lower than for symptomatic infection (52.2% (95%CI 35.3-64.7%) and 92.0% (95%CI 89.1-94.2%, respectively). Additionally, long-term protection among those aged 65 years and over was lower than for those aged under 65 years (76.3% compared to 88.9%, p<0.001).

A study conducted in the Republic of Korea¹⁰ evaluated the transmissibility of the Delta variant among household contacts. A total of 405 cases with a median age of 19 years (1-71 years) who were infected with the Delta variant between 22 June to 31 July from Daejeon metropolitan city were included the study, of whom 325 (80.2%) were symptomatic. From these cases, six local clusters (two or more confirmed infections) were identified, all of which were associated with indoor facilities with the largest related to a sports academy (n=249 cases) and the second largest, a karaoke centre (n=47 cases). It was also estimated that 80% of all local transmission was caused by 15% (95%CI 13-18%) of cases and from 258 infector-infectee transmission pairs, an estimated mean serial interval (the time between which the infector and infectee show symptoms) of 3.26 days (95% credible interval of 2.92-3.60 days) was calculated. A secondary attack rate of 63.4% (52/82 cases) was calculated based on data from 23 household

contacts in 32 homes. The study demonstrates the high transmissibility of the Delta variant in indoor settings and households. Contact tracing and isolation and the use of personal preventive measures during indoor activity remain imperative particularly given the potential for pre-symptomatic transmission.

Table 2: Summary of phenotypic impacts* of variants of concern

WHO label	Alpha	Beta	Gamma	Delta	Omicron
Transmissibility	Increased transmissibility ¹¹	Increased transmissibility ^{12,13}	Increased transmissibility ^{13,14}	Increased transmissibility ^{13,15,16}	No direct evidence for increased transmissibility.
Disease severity	Possible increased risk of hospitalization ^{17,18} , possible increased risk of severe disease and death ^{19,20}	Possible increased risk of hospitalization ¹⁸ , possible increased in-hospital mortality ²¹	Possible increased risk of hospitalization ¹⁸ , possible increased risk of severe disease ²²	Possible increased risk of hospitalization ^{23,24}	Not yet known. Clinical outcome data are under review.
Risk of reinfection	Neutralizing activity retained ²⁵ , risk of reinfection remains similar ²⁶	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²⁷	Moderate reduction in neutralizing activity reported ²⁸	Reduction in neutralizing activity reported ^{29–31}	Preliminary evidence suggests a possible increased risk of reinfection ³²
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ³³	No impact on RT-PCR or Ag RDTs observed ³¹	None reported to date	No impact on RT-PCR or Ag RDTs observed ³⁴	PCR continues to detect Omicron. Impact on Ag-RDTs is under investigation.

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

Table 3 summarizes the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to non-VOC settings. Since the [30 November update](#), a total of 10 notable new studies have provided evidence of COVID-19 vaccine performance against the variants of concern.

As of December 12, seven recent studies have provided evidence of vaccine performance against the Omicron variant: 1 VE study and 6 neutralization studies. Note all studies are preliminary and more data are needed to confirm findings.

The first study of real-world VE against the Omicron variant (not yet peer-reviewed) provides preliminary evidence of reduced effectiveness of AstraZeneca-Vaxzevria and Pfizer BioNTech-Comirnaty against symptomatic disease due to Omicron.³⁵ No data on VE against severe disease was reported.³⁵ This test-negative case-control study conducted in the United Kingdom found evidence that two doses of AstraZeneca-Vaxzevria was not effective at preventing symptomatic disease due to Omicron, at ≥ 15 weeks after the second dose. However, the authors note that early data for AstraZeneca-Vaxzevria are likely biased due to small numbers and because persons receiving two doses of the vaccine likely reflect an older population and those with more co-morbidities. VE of Pfizer BioNTech-Comirnaty against symptomatic disease was similar to Delta (88.0%, 95% CI: 65.9-95.8%) 2-9 weeks post complete vaccination, but then fell to 48.5% (24.3-65.0%) at 10-14 weeks post second dose (compared to VE of 77.7%, 95% CI: 76.3-79%, against Delta 10-14 weeks post vaccination). VE against symptomatic disease due to Omicron remained 34-37% from

15-to-25+ weeks post second dose, without evidence of further decrease. Two weeks after receiving a third dose of Pfizer BioNTech-Comirnaty, VE against symptomatic disease due to Omicron increased to 71.4% (41.8-86.0%) among those who had received a primary series of AstraZeneca-Vaxzevria and to 75.5% (95%CI: 56.1 to 86.3%) among those who had received a primary series of Pfizer BioNTech-Comirnaty; in contrast, VE of a third dose against symptomatic disease due to Delta was 93-94% when added to either primary series. While these results indicate reduced VE of AstraZeneca-Vaxzevria and Pfizer BioNTech-Comirnaty against Omicron, significant bias cannot be ruled out; differences in age and risk among early cases of Omicron among vaccinated versus unvaccinated persons, as well as the predominance of early Omicron cases among travelers and their close contacts, could explain some of the results. Moreover, due to the small number of Omicron cases detected to date, these early VE estimates are subject to significant uncertainty with wide confidence intervals.

Six studies (not yet peer reviewed) have assessed the ability of blood collected from vaccinated persons to neutralize the Omicron variant.

- One study found an average 41.3-fold reduction in neutralization capacity relative to the ancestral SARS-CoV-2 strain in 12 samples collected 10-39 days after complete vaccination with the Pfizer BioNTech-Comirnaty primary (two-dose) series.⁵
- A second study conducted by Pfizer, found a 25.8-fold reduction relative to the ancestral strain among approximately 20 samples collected 3 weeks after completion of the Pfizer BioNTech-Comirnaty primary series. The reduction was only 2.6-fold among samples collected from persons who had received a third dose of Pfizer BioNTech-Comirnaty one month prior to sample collection.³⁶
- A third study found that neutralization capacity against Omicron was reduced by 33.5-fold relative to the ancestral strain in persons receiving 2 doses of Pfizer BioNTech-Comirnaty, while the majority of samples from persons receiving two doses of AstraZeneca-Vaxzevria, failed to neutralize the variant.³⁷
- A fourth study found that blood collected from individuals who were previously vaccinated with 2 doses of mRNA vaccine 1.3 months prior showed a 127-fold reduction in capacity to neutralize Omicron relative to the ancestral strain; samples collected from persons vaccinated with Janssen-Ad26.COV 2.S 1 month prior failed to neutralize Omicron.³⁸
- A fifth study found 20-fold, 11.4- fold, and 10-fold reductions in neutralization capacity *compared to Delta* for two doses of Moderna-mRNA-1273, for two doses of Pfizer BioNTech-Comirnaty, and for a single dose of AstraZeneca-Vaxzevria followed by second dose of Pfizer BioNTech-Comirnaty, respectively, among 14-19 samples collected from persons who had received their second dose 6-7 months prior.³⁹ Previous studies have found a median 3-fold reduction (IQR 2-4) of these vaccines against Delta relative to the ancestral strain. Adding a third dose of Pfizer BioNTech-Comirnaty to each of three primary vaccination series evaluated, an increase in neutralizing antibodies was observed relative to two doses, however, neutralization capacity against Omicron *relative to Delta* was still reduced by 23- to 37-fold.
- Finally, a sixth study found that blood collected from persons vaccinated with 2 doses of AstraZeneca-Vaxzevria, 2 doses of Moderna-mRNA-1273, 2 doses of Pfizer BioNTech-Comirnaty, or 1 dose of AstraZeneca-Vaxzevria followed by a second dose of Pfizer BioNTech-Comirnaty had reduced capacity to neutralize Omicron as *compared to Alpha, Beta, and Delta variants*; a much smaller reduction in neutralization capacity against Omicron was observed for blood collected from persons who had been previously infected and then vaccinated or previously vaccinated and then infected.⁶ Of note, these neutralization studies used different assays, sera at variable times after vaccination, and most included sera from a small number of persons.

While methods vary across the studies, and neutralization is only one marker of vaccine performance, these preliminary laboratory results suggest that the effectiveness of COVID-19 vaccines against infection with the Omicron variant may be reduced.

Three studies assessed COVID-19 vaccine effectiveness in settings where Delta was the predominant circulating variant.

- The first test-negative case-control peer-reviewed study conducted at two medical centers in India found AstraZeneca-Vaxzevria to be 63.1% (51.5-72.1) effective at preventing SARS-CoV-2 infection 14 or more days post second dose, with a maximum follow-up time up to 10 weeks following the second dose.⁴⁰ Authors also report that persons infected with SARS-CoV-2, two doses of AstraZeneca-Vaxzevria was 81.5% (9.9-99.0%) effective at preventing progression to moderate-to-severe disease.
- A second peer-reviewed retrospective cohort study from Israel evaluated the effectiveness of a third dose of Pfizer BioNTech-Comirnaty in preventing death among persons 50 years and older who had completed the primary vaccination series at least 5 months prior.⁴¹ The authors found that a third dose⁴¹ had a relative VE of 90% (86-93%) effective at preventing death due to COVID-19, compared to those who had received only 2 doses; the rate of death in the third dose group was 0.16 per 100,000 person-years compared to 2.98 per 100,000 person years in persons with 2 doses only.
- A third retrospective cohort study from Israel (not yet peer reviewed), found the rate of SARS-CoV-2 infection to be 2.6 (2.4-2.7) time lower in persons having received a third dose of Pfizer BioNTech-Comirnaty in the previous two months relative to persons who had received their second dose in the prior two months.⁴² The study also found evidence of decreasing VE of two doses of Pfizer BioNTech-Comirnaty over time, with a 4-fold increase in the rate of infection among those receiving a second dose 6-8 months prior compared to those who had received their second dose only 0-2 months earlier.

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table.

African Region

The African Region reported over 167 000 new cases, an increase of 111% as compared to the previous week and the highest number of new weekly cases since early August 2021. Marked increases were observed in over two thirds (33/49; 67%) of countries in the Region with the majority (30/33; 91%) reporting increases of 25% or greater, as compared to the previous week. The highest numbers of new cases were reported from South Africa (109 053 new cases; 183.9 new cases per 100 000 population; a 76% increase), Zimbabwe (26 479 new cases; 178.2 new cases per 100 000; a 479% increase), and Mauritius (6415 new cases; 504.4 new cases per 100 000; a 775% increase).

The Region reported just under 500 new deaths, a number similar to the number reported in the previous week. The highest numbers of new deaths were reported from South Africa (151 new deaths; <1 new death per 100 000 population; a 13% decrease), Mauritius (92 new deaths; 7.2 new deaths per 100 000; a 27% decrease), and Algeria (41 new deaths; <1 new death per 100 000; a 7% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 837 000 new cases and over 10 000 new deaths, decreases of 10% and 14% respectively as compared to the previous week. Nevertheless, 28% (15/56) of countries in the Region reported over 10% increases in cases, with the greatest observed in the Caribbean islands of Saint Barthélemy (350%; from 2 cases to 9 cases), Turks and Caicos Islands (285%) and Saint Martin (111%). The highest numbers of new cases were reported from the United States of America (674 019 new cases; 203.6 new cases per 100 000; a 9% decrease), Brazil (38 372 new cases; 18.1 new cases per 100 000; a 38% decrease), and Canada (25 332 new cases; 67.1 new cases per 100 000; a 25% increase).

The highest numbers of new deaths were reported from the United States of America (6909 new deaths; 2.1 new deaths per 100 000; a 16% decrease), Mexico (1122 new deaths; <1 new death per 100 000; an 85% increase), and Brazil (851 new deaths; <1 new death per 100 000; a 41% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The weekly incidence of cases and deaths in the Eastern Mediterranean Region remained stable this week, with over 90 000 new cases and over 1500 new deaths reported. However, three countries (3/22, 13%) in the Region reported an increase of over 10% in weekly incidence of cases. The highest numbers of new cases were reported from Jordan (34 735 new cases; 340.4 new cases per 100 000; an 8% increase), the Islamic Republic of Iran (21 168 new cases; 25.2 new cases per 100 000; a 19% decrease), and Lebanon (11 341 new cases; 166.2 new cases per 100 000; a 9% increase).

The highest numbers of new deaths continued to be reported from the Islamic Republic of Iran (537 new deaths; <1 new death per 100 000; a 7% decrease), Egypt (333 new deaths; <1 new death per 100 000; a 12% decrease), and Jordan (226 new deaths; 2.2 new deaths per 100 000; a 13% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported just under 2.6 million new cases, a 7% decrease as compared to the previous week and a decline since early September. The number of new deaths reported this week was just over 28 000, remaining similar to the number reported in the previous week. Despite the declining trend, a small proportion (10/61; 6%) of countries still reported over a 10% increase in cases as compared to the previous week. The highest numbers of new cases were reported from Germany (351 738 new cases; 422.9 new cases per 100 000; an 11% decrease), the United Kingdom (350 340 new cases; 516.1 new cases per 100 000; a 13% increase), and France (335 972 new cases; 516.6 new cases per 100 000; a 19% increase).

The highest numbers of new deaths were reported from the Russian Federation (8205 new deaths; 5.6 new deaths per 100 000; a similar number to that of the previous week), Poland (2804 new deaths; 7.4 new deaths per 100 000; a 6% increase), and Ukraine (2747 new deaths; 6.3 new deaths per 100 000; a 13% decrease).

Updates from the [European Region](#)

South-East Asia Region

The declining trend in reported new weekly cases and deaths continued this week in the South-East Asia Region. Over 98 000 new cases and over 2600 new deaths were reported, amounting to a 10% and 50% decrease respectively as compared to the previous week. Only two countries reported an increase in weekly cases, Bangladesh (from 1659 to 1882, a 13% increase) and Bhutan (from 1 to 8; a 700% increase). The highest numbers of new cases were reported from India (57 255 new cases; 4.1 new cases per 100 000; a 6% decrease), Thailand (27 405 new cases; 39.3 new cases per 100 000; a 20% decrease), and Sri Lanka (5220 new cases; 24.4 new cases per 100 000; similar to the number reported in the previous week).

The highest numbers of new deaths were reported from India (2108 new deaths; <1 new death per 100 000; a 56% decrease), Thailand (227 new deaths; <1 new death per 100 000; similar to the number reported in the previous week), and Sri Lanka (153 new deaths; <1 new death per 100 000; similar to the number reported in the previous week).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported 214 000 new cases, a 7% increase as compared to the previous week. Four of the 27 countries in the region, reported an increase in case incidence of over 10%, Northern Mariana Islands (62%), Republic of Korea (37%), Lao People's Democratic Republic (17%) and Japan (12%). The highest numbers of new cases were reported from Viet Nam (103 635 new cases; 106.5 new cases per 100 000; a 6% increase), Republic of Korea (44 238 new cases; 86.3 new cases per 100 000; a 38% increase), and Malaysia (33 675 new cases; 104.0 new cases per 100 000; similar to the number reported in the previous week).

The Region reported over 3300 new deaths, a number similar to that of the previous week. The highest numbers of new deaths were reported from Viet Nam (1550 new deaths; 1.6 new deaths per 100 000; a 13% increase), the Philippines (866 new deaths; <1 new death per 100 000; a 16% decrease), and Republic of Korea (401 new deaths; <1 new death per 100 000; a 32% increase).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 13 December, highlights include the following:

- WHO provides testing kits to Uganda for screening the COVID-19 Omicron variant of concern
- COVID-19 Contact Tracing Communication in Honduras
- WHO/Europe laboratory system strengthening mission to Kazakhstan
- UN agencies support intensive COVID-19 vaccination drive in the Philippines
- Emergency Medical Teams (EMT) in the Pacific: Strengthening national capacity for health emergency response
- Updates on WHO's financing to support countries on COVID-19 response implementation to suppress transmission, reduce exposure, and protect the vulnerable and save lives
- Progress on a subset of global indicators that demonstrate country and global progress to end the acute phase of the pandemic

Annexes

Annex 1. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Neutralization studies that use samples collected >7 days and < 6 months after complete vaccination and that use an ancestral strain as the reference are included in Table 3.

unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)

Annex 3. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 69, published 7 December 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [Update on Variant of Concern Omicron](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 5 December 2021

Globally, weekly case incidence plateaued this week (29 November - 5 December 2021), with over 4 million confirmed new cases reported, similar to the number reported in the previous week's figures. However, new weekly deaths increased by 10% as compared to the previous week, with over 52 500 new deaths reported. As of 5 December, nearly 265 million confirmed cases and over 5.2 million deaths have been reported globally.

The African Region and the Region of the Americas reported increases in new weekly cases of 79% and 21%, respectively, while the Western Pacific and South-East Asia regions both reported decreases of 10%. The number of new weekly cases reported by the European and Eastern Mediterranean regions were similar to the numbers reported in the previous week. New weekly deaths increased by 49% in the South-East Asia Region and 38% in the Region of the Americas, while the weekly deaths decreased in the African and Eastern Mediterranean Regions by 13% and 8%, respectively. The number of new deaths were similar to those reported in the previous week in both the European and the Western Pacific regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 5 December 2021**

**See [Annex 2: Data, table, and figure notes](#)

The regions reporting the highest weekly case incidence per 100 000 population continue to be the European Region (288.0 new cases per 100 000 population) and the Region of the Americas (91.4 new cases per 100 000 population). Both regions also reported the highest weekly incidence in deaths of 3.1 and 1.3 per 100 000 population, respectively while <1 new death per 100 000 was reported in all other regions.

The highest numbers of new cases were reported from the United States of America (752 394 new cases; a 30% increase), Germany (396 429 new cases; similar to the previous week's figures), the United Kingdom (310 696 new cases; similar to the previous week's figures), France (283 500 new cases; a 49% increase) and the Russian Federation (231 240 new cases; similar to the previous week's figures).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 5 December 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 687 257 (65%)	-3%	88 925 399 (34%)	28 990 (55%)	-2%	1 569 599 (30%)
Americas	935 062 (23%)	21%	97 679 255 (37%)	12 987 (25%)	38%	2 360 315 (45%)
Western Pacific	199 495 (5%)	-10%	10 370 429 (4%)	3 220 (6%)	2%	144 204 (3%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Potential Variants of Concern (VOCs), Variants of Interest (VOIs) or Variants Under Monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, declining trend in the proportion of Alpha, Beta and Gamma, and the emergence of Omicron which was designated as a [Variant of Concern on 26 November](#) (Figures 4 and 5). At present, Omicron cases have been reported in 57 countries across all WHO regions. While most of the cases identified in these countries are currently travel-related, this may change as more information becomes available. Of 899 935 sequences uploaded to [GISAID](#) with specimens collected in the last 60 daysⁱ, 897 886 (99.8%) were Delta, 713 (0.1%) were Omicron, 286 (<0.1%) Gamma, 154 (<0.1%) Alpha, 64 (<0.1%) Beta, and <0.1% comprised other circulating variants (including VOIs Mu and Lambda).

Sub-regional and country-level variation continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual, and other variants (e.g., Gamma, Lambda, Mu) still contribute a large proportion of reported sequences.

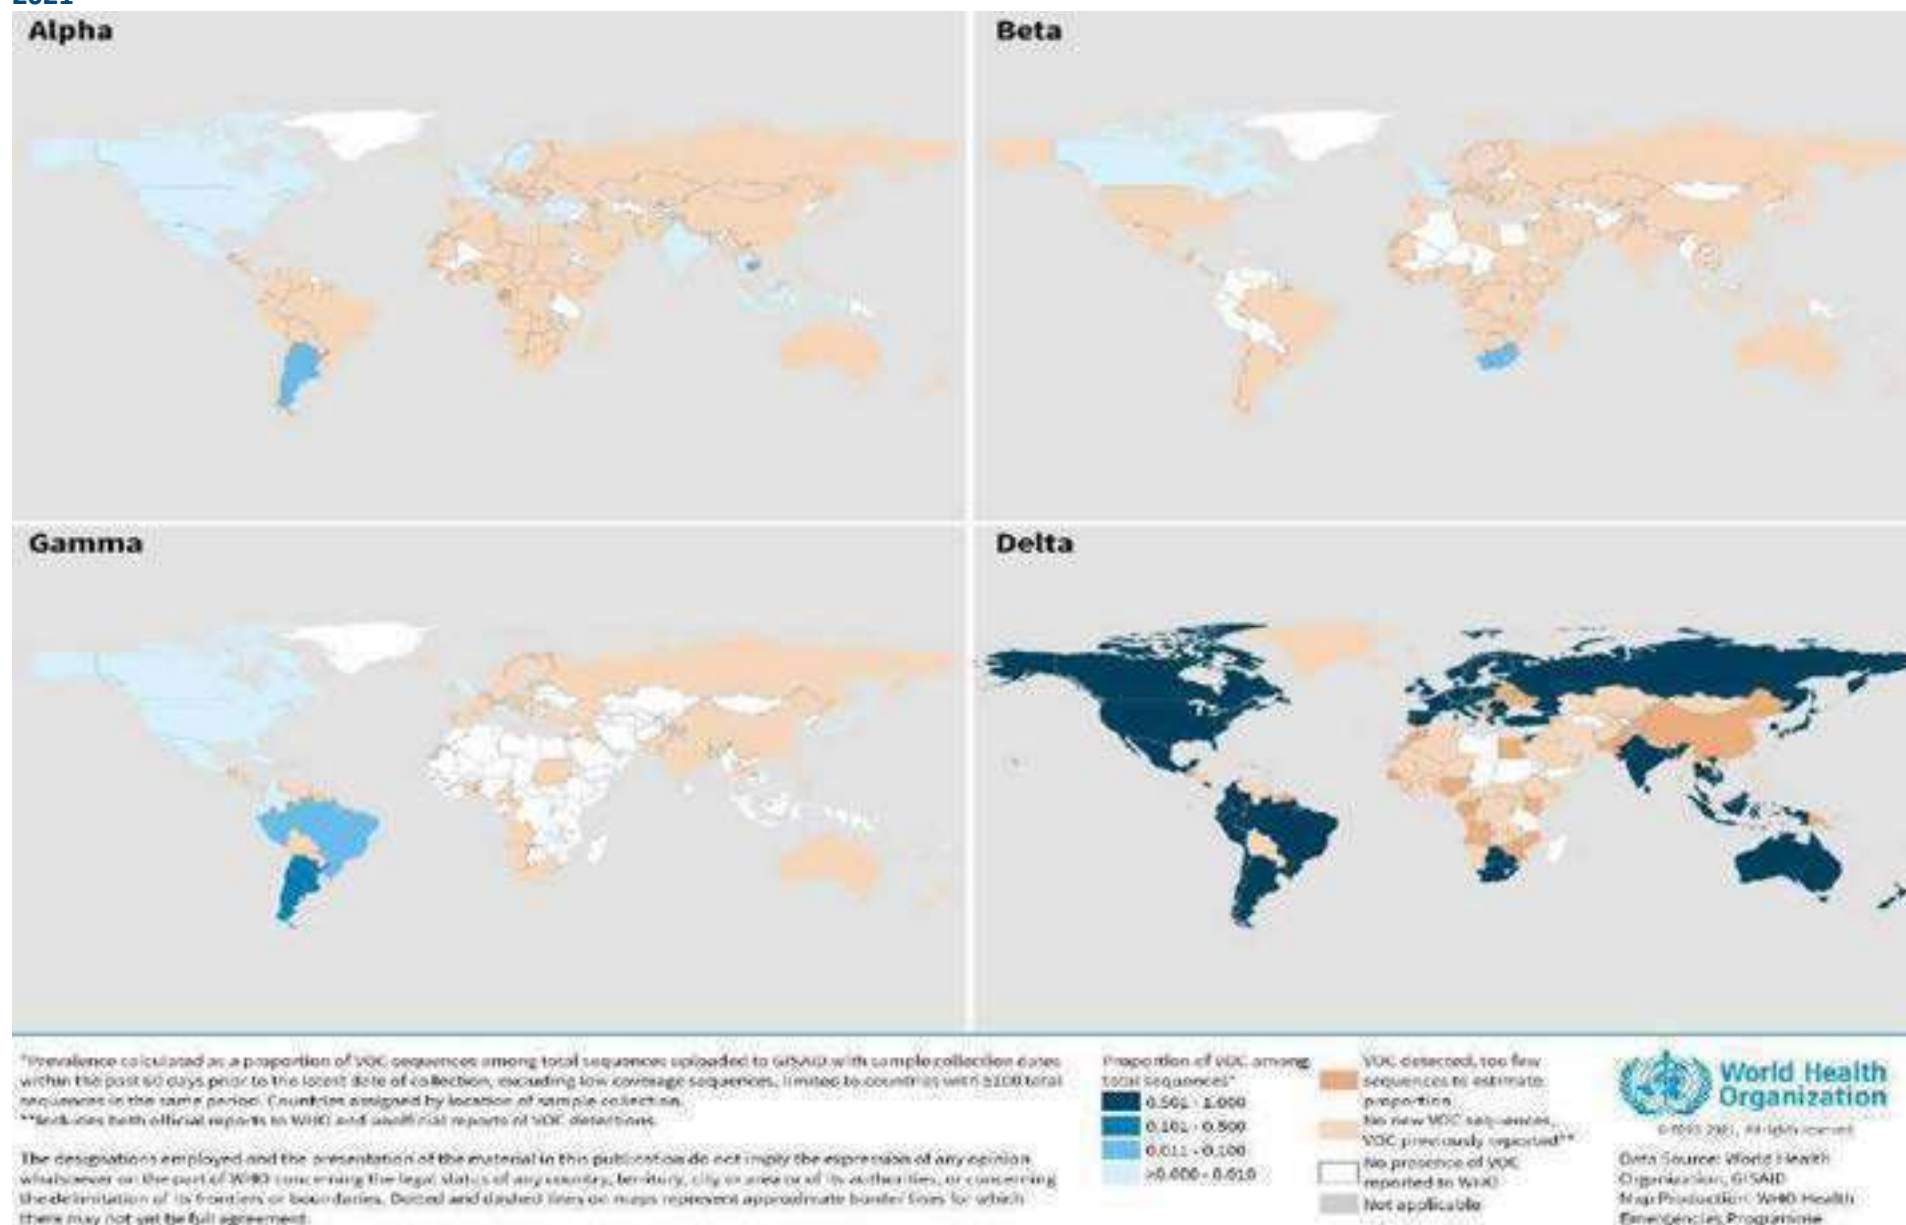

To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

- [Genomic sequencing of SARS-CoV-2: a guide to implementation for maximum impact on public health](#)
- [Considerations for implementing and adjusting PHSM in the context of COVID-19](#)

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 3 October to 2 December 2021 (last reported sample at the time of data extraction), excluding low coverage sequences.

Figure 4. Prevalence of Variants of Concern (VOCs) Alpha, Beta, Gamma and Delta in the last 60 days and historic detections, data as of 7 December 2021

Prevalence data based on sequences reported to [GISAID](#), excluding low coverage sequences. See also [Annex 1](#) for reported VOC detections by country/territory/area

Figure 5. Presence of Variant of Concern (VOC) Omicron, data as of 7 December 2021 (4 pm CET)

Presence of the Omicron variant is based on information reported to WHO. It includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). See also [Annex 1](#) for reported VOC detections by country/territory/area.

Update on Variant of Concern Omicron

Background

Omicron is the fifth SARS-CoV-2 variant to be designated as a Variant of Concern (VOC) by WHO, following the designation of the Alpha, Beta, Gamma and Delta variants. The first known laboratory-confirmed case of Omicron was identified from a specimen collected on 9 November 2021 in South Africa, with the variant (Pango nomenclature B.1.1.529) first reported to WHO on 24 November. In consultation with the Technical Advisory Group on Virus Evolution (TAG-VE), WHO designated B.1.1.529 as a VOC on 26 November in view of the potential for enhanced transmissibility and/or a degree of immune escape, given the number of mutations (26-32) in the spike protein, as well as concerning initial epidemiological reports from South Africa, including signals of increased risk of reinfection. Here, we present an update on the current situation in terms of the epidemiology and transmissibility, clinical severity, risk of reinfection and the potential impact on diagnostics, vaccines and therapeutics.

As more data are analysed and understood about the potential implications that Omicron may have on the epidemiology, transmissibility, clinical severity, prevention and treatment of SARS-CoV-2 infection, our understanding of this variant will continue to evolve, and we will issue updates as further evidence becomes available.

Epidemiology

In South Africa, where Omicron was first reported, the case incidence of COVID-19 has continued to rise since the second week of November, with 62 021 new cases reported between 29 November and 5 December, a 111% increase compared to the previous week. An increase in the test positivity rate (TPR) has also been seen from 1.2% the week beginning the 7 November, to 22.4% the week beginning the 2 December.¹ An initial increase in incidence in Gauteng province in mid-November was thought in part, to be due to a cluster of cases among students at a university.² Very large increases in the weekly incidence of cases have also been seen in some countries neighbouring South Africa including: Eswatini (1990%); Zimbabwe (1361%); Mozambique (1207%), Namibia (681%) and Lesotho (219%). These other countries have very low vaccination coverage ranging from 12.1% of the total population fully vaccinated in Namibia to 26.7% in Lesotho. In South Africa 25.2% of the total population is fully vaccinated. While drivers of these increases remain unknown, it is plausible that spread of Omicron in combination with enhanced testing following the declaration of a VOC, play a role, together with the relaxation of public health and social measures (PHSMs) and sub-optimal immunization coverage.

Among countries in other regions reporting increasing spread of the Omicron variant, hundreds of cases of this variant have now been reported from countries in other regions.³ Since the last update published on 30 November, additional countries across all six WHO Regions have reported confirmed cases of the Omicron variant. As of 7 December 2021, the Omicron variant has been confirmed in 57 countries. However, given the predominant circulation of the Delta variant in many countries, particularly in countries in the European Region and in the United States of America, it is too early to draw any conclusions about the impact of Omicron will have on the global epidemiology of COVID-19.

Transmissibility

While there seems to be evidence that the Omicron variant may have a growth advantage over other circulating variants it is unknown whether this will translate into increased transmissibility. Based on several assumptions about

the growth advantage, timing of introduction in the European Region, and population mixing and public health and social measures (PHSM) implementation, the European Centre for Disease Prevention and Control,⁴ forecasted that if 1% of SARS-CoV-2 infections are due to the Omicron variant, it will become dominant in Europe, comprising >50% of the new infections, by 1 January 2022, with a growth advantage of >120%; and by 1 March 2022 with a growth advantage of >30%.

Ongoing and planned epidemiological studies, including detailed cluster investigations, contact-tracing and household transmission studies, coupled with neutralization studies from people previously vaccinated or infected and studies of vaccine effectiveness will help improve our understanding of the interplay between increased transmissibility and immune escape as drivers of increased transmission.

Clinical severity

Currently only limited data are available, making it challenging to assess any changes in disease severity with the Omicron variant. As of 6 December, all of the 212 confirmed cases identified in 18 European Union countries for which there was information available on severity were asymptomatic or mild.³ While South Africa saw an 82% increase in hospital admissions due to COVID-19 (from 502 to 912) during the week 28 November – 4 December 2021, it is not yet known the proportion of these with the Omicron variant.⁵ Even if the severity is equal or potentially even lower than for Delta variant, it is expected that hospitalizations will increase if more people become infected and that there will be a time lag between an increase in the incidence of cases and an increase in the incidence of deaths. Further information is needed to fully understand the clinical picture of those infected with the Omicron variant and WHO encourages countries to contribute to the collection and sharing of hospitalized patient data through the [WHO COVID-19 Clinical Data Platform](#).

Risk of reinfection

Preliminary analysis suggests that the mutations present in the Omicron variant may reduce neutralising activity of antibodies resulting in reduced protection from natural immunity. This may explain why the variant seems to be spreading rapidly in a highly immune population such as South Africa, in which current vaccination coverage in adults is about 35%, but in which seroprevalence levels are estimated to be as high as 60-80% due to past infections, according to recent epidemiological studies and modelling.⁶

A modelling study (pre-print) based on data from nearly three million individuals in South Africa with a laboratory confirmed infection at least 90 days prior found an increase in the risk of re-infection during November 2021 compared to time periods earlier in the pandemic (estimated relative hazard ratio for reinfection versus primary infection of 2.39 (95%CI 1.88-3.11 from 1 – 27 November 2021 compared to wave 1 (June – September 2020), corresponding with the emergence of the Omicron variant. This information provides an initial assessment of the risk of re-infection however, further studies are needed to confirm this, including the ability of the Omicron variant to infect or re-infect those who have been vaccinated, as well as to determine the severity of these breakthrough or re-infections.⁷

Impact on diagnostics

SARS-CoV-2 infection can be diagnosed using either molecular tests (NAAT, PCR) or antigen-detection assays. Interim guidance on diagnostic testing for SARS-CoV-2 can be found [here](#) and on the use of antigen-detection tests can be found [here](#). PCR tests that include multiple gene targets are unlikely to be affected and should continue to be used

to detect SARS-CoV-2 infection, including the Omicron variant. This has been confirmed by statements issued by suppliers as well as the US FDA, based on sequence analysis.

The majority of Omicron variant sequences reported include a 69-70 deletion mutation in the Spike protein. There are some public sequences lacking this mutation and, at the present time, it is unclear if this reflects true sequence diversity or is a sequencing artifact. Presence of the 69-70 deletion causes dropout of some S-gene targets in PCR assays, such as the TaqPath COVID-19 Combo Kit and TaqPath COVID-19 CE-IVD RT-PCR Kit (Thermo Fisher Scientific). This S-gene target failure (SGTF) can be used as a marker suggestive of Omicron. However, confirmation should be performed by sequencing the sample, as this deletion is found in other VOCs (e.g., Alpha and subsets of Gamma and Delta) currently circulating at low levels globally, but possibly circulating at higher levels locally.

All four WHO emergency use listing (EUL) approved antigen-detection rapid diagnostic tests (Ag-RDTs), listed [here](#), target the Nucleocapsid protein of SARS-CoV-2. The vast majority of Omicron sequences reported to date include the G204R and R203K mutations in the Nucleocapsid protein, which are present in many other variants currently in circulation. This has not been reported to affect the accuracy of Ag-RDTs to detect SARS-CoV-2. In addition, the majority of Omicron sequences contain a 3 amino acid deletion at positions 31-33 and the P13L mutation in the Nucleocapsid protein. The specific impact of these mutations on the performance of Ag RDTs is currently unclear.

Official statements from several Ag-RDT suppliers, including two with EUL-approved assays, indicate that based on sequence analysis, the performance of their tests is not impacted by the Omicron variant. Preliminary laboratory evidence is emerging that independently confirms that Ag-RDTs can accurately diagnose infection with the Omicron variant. To date, there have been no reported misdiagnoses (false negative results) for any WHO EUL approved diagnostic product in relation to Omicron.

Impact on vaccines

There is a need for more data to assess whether the mutations present on the Omicron variant may result in reduced protection from vaccine derived immunity and data on vaccine effectiveness, including the use of additional vaccination doses. WHO will continue to work with partners to monitor and evaluate these data once they become available. Vaccine effectiveness studies are vital to understand how vaccines protect against infection, symptomatic and severe disease, and death. WHO guidance on best practices to conduct these types of studies can be found on our [website](#).

Impact on treatments

WHO continues to work with researchers to understand the effectiveness of treatments against the Omicron variant; however, Interleukin-6 Receptor Blockers and corticosteroids are expected to continue to be effective in the management of patients with severe disease.

Conclusions

Whilst many questions about the Omicron variant remain unanswered, more information will continue to emerge in the coming weeks, with the TAG-VE and other groups reviewing and analysing data as it becomes available. It is important to continue to accelerate access to vaccines globally and for countries to continue to enhance surveillance, reporting initial cases or clusters to WHO and share genome sequences on publicly available databases such as GISAID. We recommend the public continue to prevent the spread of SARS-CoV-2 by improving ventilation of indoor spaces, wearing well-fitted masks, avoiding crowded spaces, practising hand hygiene and keeping an appropriate physical distance from others.

African Region

The case incidence in the African Region continues to increase with over 79 000 new cases reported during the week of 29 November to 5 December, a 79% increase. However, weekly deaths have continued to decrease, with just under 500 new deaths reported in the past week, a 13% decrease. Twenty-one of the 49 countries in the region (43%) reported an increase of >10% in new cases as compared to the previous week, with the highest numbers of new cases reported from South Africa (62 021 new cases; 104.6 new cases per 100 000; a 111% increase), Zimbabwe (4572 new cases; 30.8 new cases per 100 000; a 1361% increase) and Réunion (2140 new cases; 239.0 new cases per 100 000; a 14% increase). However, proportionally, very large increases in the incidence of cases were also seen in Eswatini (1900%), Mozambique (1207%) and Namibia (681%).

Six of the 49 countries in the Region reported an increase of over 10% in the number of new weekly deaths, with the highest numbers of new deaths reported from South Africa (174 new deaths; <1 new death per 100 000; a 21% decrease), Mauritius (126 new deaths; 9.9 new deaths per 100 000; an 31% increase), and Ethiopia (58 new deaths; <1 new death per 100 000; a 9% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported a 21% increase in case incidence in the past week, with over 935 000 new cases reported. This trend is largely driven by the increase in the incidence of cases reported in the United States of America (752 394 new cases; 227.3 new cases per 100 000; a 30% increase). Twenty-seven percent (15/56) of countries in the region reported increases of over 10%. In addition to the United States of America, countries reporting the highest numbers of cases included Brazil (61 779 new cases; 29.1 new cases per 100 000; similar to the previous week's figures) and Canada (20 188 new cases; 53.5 new cases per 100 000; similar to the previous week's figures).

The incidence of deaths also increased with just under 13 000 new deaths reported, a 38% increase compared to the previous week. The highest numbers of new deaths were reported from the United States of America (8527 new deaths; 2.6 new deaths per 100 000; a 56% increase), Brazil (1443 new deaths; <1 new death per 100 000; a 9% decrease) and Mexico (1002 new deaths; <1 new death per 100 000; a 55% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The weekly incidence of cases in the Eastern Mediterranean Region remained stable with over 94 000 new cases reported. The weekly incidence of deaths decreased by 8%, with over 1600 reported. However, nearly half (10/22) of countries in the region reported a >10% increase in weekly incidence of cases. Most cases continued to be reported from three countries: Jordan (32 108 new cases; 314.7 new cases per 100 000; a 15% increase), the Islamic Republic of Iran (26 255 new cases; 31.3 new cases per 100 000; an 18% decrease), and Lebanon (10 406 new cases; 152.5 new cases per 100 000; an 11% increase).

The highest numbers of new deaths continued to be reported from the Islamic Republic of Iran (575 new deaths; <1 new death per 100 000; an 18% decrease), Egypt (377 new deaths; <1 new death per 100 000; a 13% decrease), and Jordan (200 new deaths; 2.0 new deaths per 100 000; a 19% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

Following an increase in the incidence of cases from mid-October, the weekly number of new cases in the European Region plateaued this week with just over 2.6 million new cases reported. The incidence in deaths also remained stable compared to the previous week, with over 29 000 new deaths reported. Fewer countries (11/61, 18%) reported an increase in new weekly cases of over 10% compared to the previous week. Germany and the United Kingdom continue to report the highest number of new cases with 396 429 new cases (476.7 new cases per 100 000; similar to the previous week's figures) and 310 696 new cases (457.7 new cases per 100 000; similar to the previous week's figures), respectively, with France reporting the third highest number of new cases (283 500 new cases; 435.9 new cases per 100 000; a 49% increase).

The highest numbers of new deaths continued to be reported from the Russian Federation (8523 new deaths; 5.8 new deaths per 100 000; similar to the previous week's figures); Ukraine (3163 new deaths; 7.2 new deaths per 100 000; an 18% decrease) and Poland (2636 new deaths; 6.9 new deaths per 100 000; a 19% increase).

Updates from the [European Region](#)

South-East Asia Region

Since July 2021, the incidence of cases in the South-East Asia Region has continued to decline with over 109 000 new cases reported this week, a 10% decrease as compared to the previous week. Only one country reported an increase of over 10%, Timor-Leste (6 new cases; <1 case per 100 000; a 100% increase). The highest number of new cases continued to be reported from India (60 732 new cases; 4.4 new cases per 100 000; similar to the previous week's figures), Thailand (34 428 new cases; 49.3 new cases per 100 000; an 18% decrease) and Sri Lanka (5162 new cases; 24.1 new cases per 100 000; a 12% decrease).

The number of new weekly deaths however, increased by 49% as compared to the previous week, with over 5300 new deaths reported this week, the majority being reported from India (4772 new deaths; <1 new death per 100 000; a 65% increase). While Thailand and Sri Lanka reported the second and third highest number of deaths this past week, both countries reported a decline (237 new deaths; <1 new death per 100 000; a 26% decrease, and 156 new deaths; <1 new death per 100 000; a 12% decrease, respectively).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Following an increase in the weekly case incidence in the Western Pacific Region from early November, in the past week a 10% decrease was seen with just under 200 000 new cases reported. However, five of the 27 countries in the region reported an increase in case incidence of >10%, including French Polynesia (3976%), China (147%), the Northern Mariana Islands (75%), the Republic of Korea (26%) and Fiji (20%). The highest number of new cases continued to be reported from Viet Nam (97 374 new cases; 100.0 new cases per 100 000; a 14% decrease), Malaysia (34 897 new cases; 107.8 new cases per 100 000; an 8% decrease) and the Republic of Korea (32 142 new cases; 62.7 new cases per 100 000; a 26% increase).

The region reported over 3200 new deaths this week, similar to the previous week's figures. Two of the three countries reporting the highest numbers of new deaths showed an increasing trend: Viet Nam (1369 new deaths; 1.4 new deaths per 100 000; a 36% increase) and the Republic of Korea (304 new deaths; <1 new death per 100 000; an 11% increase), while the Philippines reported a decrease (1025 new deaths; <1 new death per 100 000; a 21% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 7 December, highlights include the following:

- Kenya increases uptake and equity for COVID-19 vaccinations
- Supporting Omicron variant detection and COVID-19 response in southern Africa
- New oxygen production stations to be constructed in Yemen
- “Data for action”: WHO/Europe pilots enhanced Emergency Response Information Management System (ERIMS) with Azerbaijan
- Home-based care for COVID-19 patients begins with community engagement in Lao People's Democratic Republic
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies

iant was received by WHO from unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 68, published 30 November 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 28 November 2021

Globally, weekly case incidence plateaued this week (22-28 November 2021), with nearly 3.8 million confirmed new cases reported, similar to the previous week's figures. However, new weekly deaths decreased by 10% in the past seven days as compared to the previous week, with over 47 500 new deaths reported. As of 28 November, over 260 million confirmed cases and nearly 5.2 million deaths have been reported globally.

The African, Western Pacific and European Regions reported increases in new weekly cases of 93%, 24% and 7%, respectively, while the Regions of the Americas and South-East Asia reported decreases of 24% and 11%, respectively. To note, the increase in the African Region was largely due to batch reporting of antigen tests by South Africa last week, therefore the trends should be interpreted with caution. The incidence in cases in the Eastern Mediterranean Region was stable with figures similar to the previous week. New weekly deaths decreased by 36% and 8% in the Regions of the Americas and the Eastern Mediterranean, respectively, and increased by 26% and 7% in the South-East Asia and African Regions, respectively. The number of new deaths were similar to the numbers reported in the previous week in both the European and Western Pacific Regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 28 November 2021**

**See [Annex 3: Data, table, and figure notes](#)

The regions reporting the highest weekly case incidence per 100 000 population continue to be the European Region (285.2 new cases per 100 000 population) and the Region of the Americas (64.5 new cases per 100 000 population). The European Region also reported the highest weekly incidence in deaths of 3.1 per 100 000 population while <1 new death per 100 000 was reported in all other regions.

The highest numbers of new cases were reported from the United States of America (464 800 new cases; a 31% decrease), Germany (406 754 new cases; a 22% increase), the United Kingdom (304 374 new cases; an 8% increase), the Russian Federation (239 215 new cases; an 8% decrease) and France (190 402 new cases; a 62% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 28 November 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 660 956 (70%)	7%	86 151 591 (33%)	29 096 (61%)	-2%	1 540 178 (30%)
Americas	659 605 (17%)	-24%	96 627 452 (37%)	9 397 (20%)	-36%	2 346 007 (45%)
Western Pacific	220 501 (6%)	24%	10 170 912 (4%)	3 160 (7%)	0%	140 984 (3%)
South-East Asia	120 704 (3%)	-11%	44 529 941 (17%)	3 574 (8%)	26%	706 336 (14%)
Eastern Mediterranean	94 382 (2%)	2%	16 751 411 (6%)	1 772 (4%)	-8%	309 105 (6%)
Africa	43 730 (1%)	93%	6 261 502 (2%)	525 (1%)	7%	152 731 (3%)
Global	3 799 878 (100%)	0%	260 493 573 (100%)	47 524 (100%)	-10%	5 195 354 (100%)

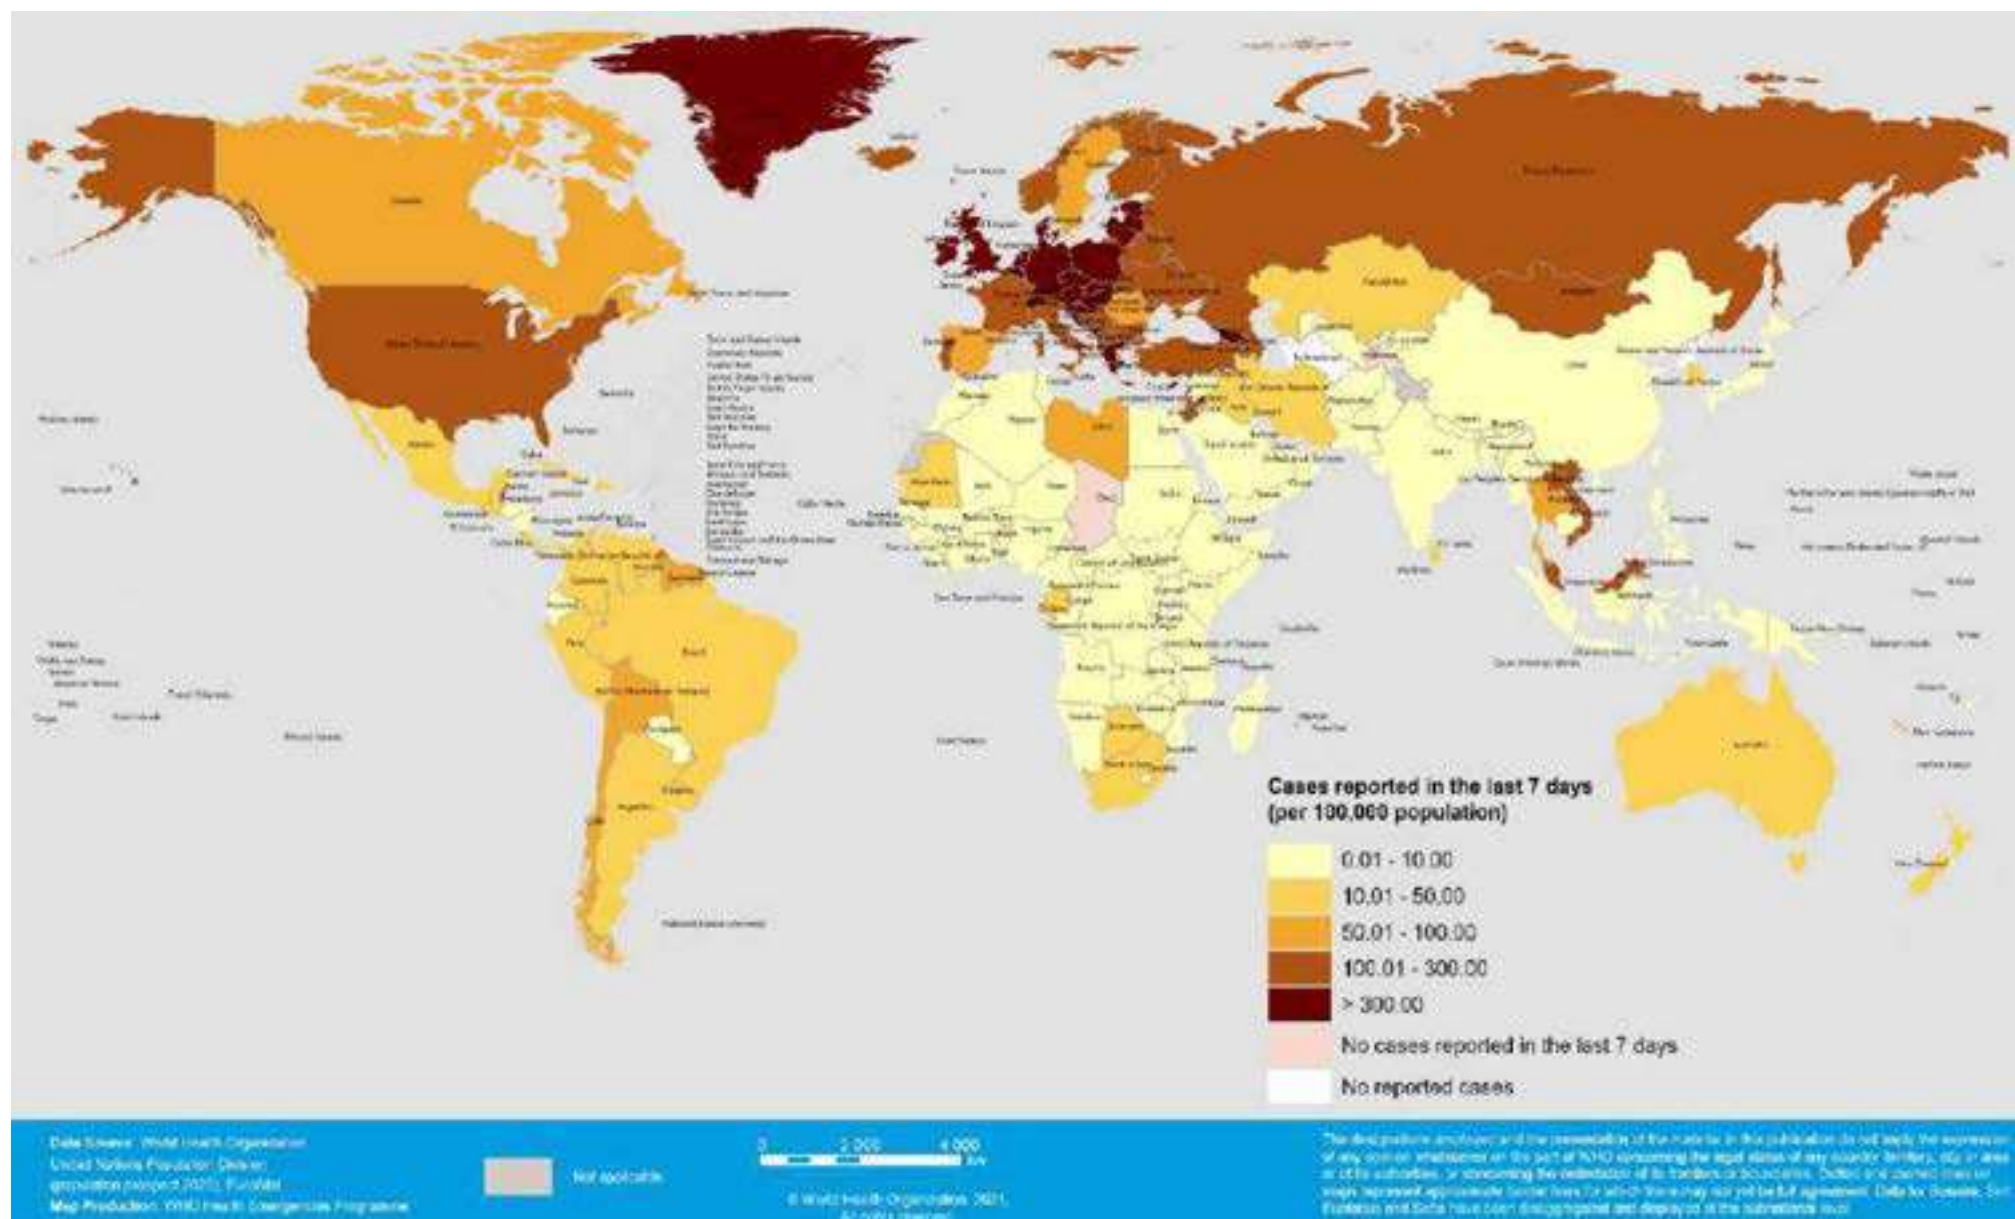

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Potential Variants of Concern (VOCs), Variants of Interest (VOIs) or Variants Under Monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

VOC Omicron (B.1.1.529)

On 26 November 2021, the Technical Advisory Group on SARS-CoV-2 Virus Evolution (TAG-VE) advised WHO that the [B.1.1.529 variant should be designated as a VOC](#). It has been given the name Omicron. The decision to designate it as a VOC was based on the evidence presented to the TAG-VE that Omicron has several mutations (including 26-32 in the spike protein) which may enhance its transmissibility and/or enable some degree of immune escape. The B.1.1.529 variant was first reported to WHO on 24 November 2021 from South Africa, while the first known laboratory-confirmed case was identified from a specimen collected on 9 November 2021.

On 28 November 2021, WHO published a [technical brief with priority actions for Member States](#). Cases of Omicron have already been identified in a number of countries, with a high likelihood of further spread. There is preliminary evidence suggesting that Omicron may have potential immune escape and/or possibly higher transmissibility, as compared to previous VOCs, that could lead to further surges. As a result of this, the overall global risk related to the new VOC Omicron in the context of the COVID-19 pandemic is very high. The evidence for this assessment contains considerable uncertainty and will be updated as more information becomes available.

Based on available evidence, a list of priority actions for Member States has been recommended including:

- Enhance surveillance and sequencing activities to understand the extent of circulation of SARS-CoV-2 variants, including Omicron.
- Submit complete genome sequences and associated metadata to a publicly available database, such as [GISAID](#).
- Where applicable, use the S gene target failure (SGTF) on certain Polymerase Chain Reaction (PCR) tests as a marker for Omicron infection.
- Report initial cases/clusters of Omicron infections to WHO through the International Health Regulations (2005) mechanism; thereafter, report the relative prevalence of Omicron amongst sequenced samples and/or, where available, the number of SGTF out of the number of samples tested.
- Continue to report evidence-based information on other circulating variants by authorities in a regular, timely and transparent manner.
- Accelerate the coverage of COVID-19 vaccination as rapidly as possible, particularly amongst those who are unvaccinated or partially vaccinated and are in a population at high priority for vaccination.
- Use a risk-based approach to adjust [international travel measures](#) in a timely manner, and report to WHO the application of time-limited measures affecting international travel and trade.

- Reduce transmission of SARS-CoV-2 via the use of well-fitted masks, physical distancing, hand hygiene, adequate ventilation of indoor spaces, and avoiding crowded spaces.
- Allow public health and social measures to be adjusted efficiently, depending on the local transmission scenario.
- Prepare and ensure essential health services can be maintained including the necessary health care resources, when demand on health care services is high.

At the present time, [WHO is coordinating](#) with a large number of researchers around the world to better understand Omicron. Studies currently or soon to be underway include assessments of transmissibility, clinical presentation including severity, risk of reinfection, and the performance of vaccines, diagnostic tests, and therapeutics against this variant.

Geographic spread and prevalence of VOCs

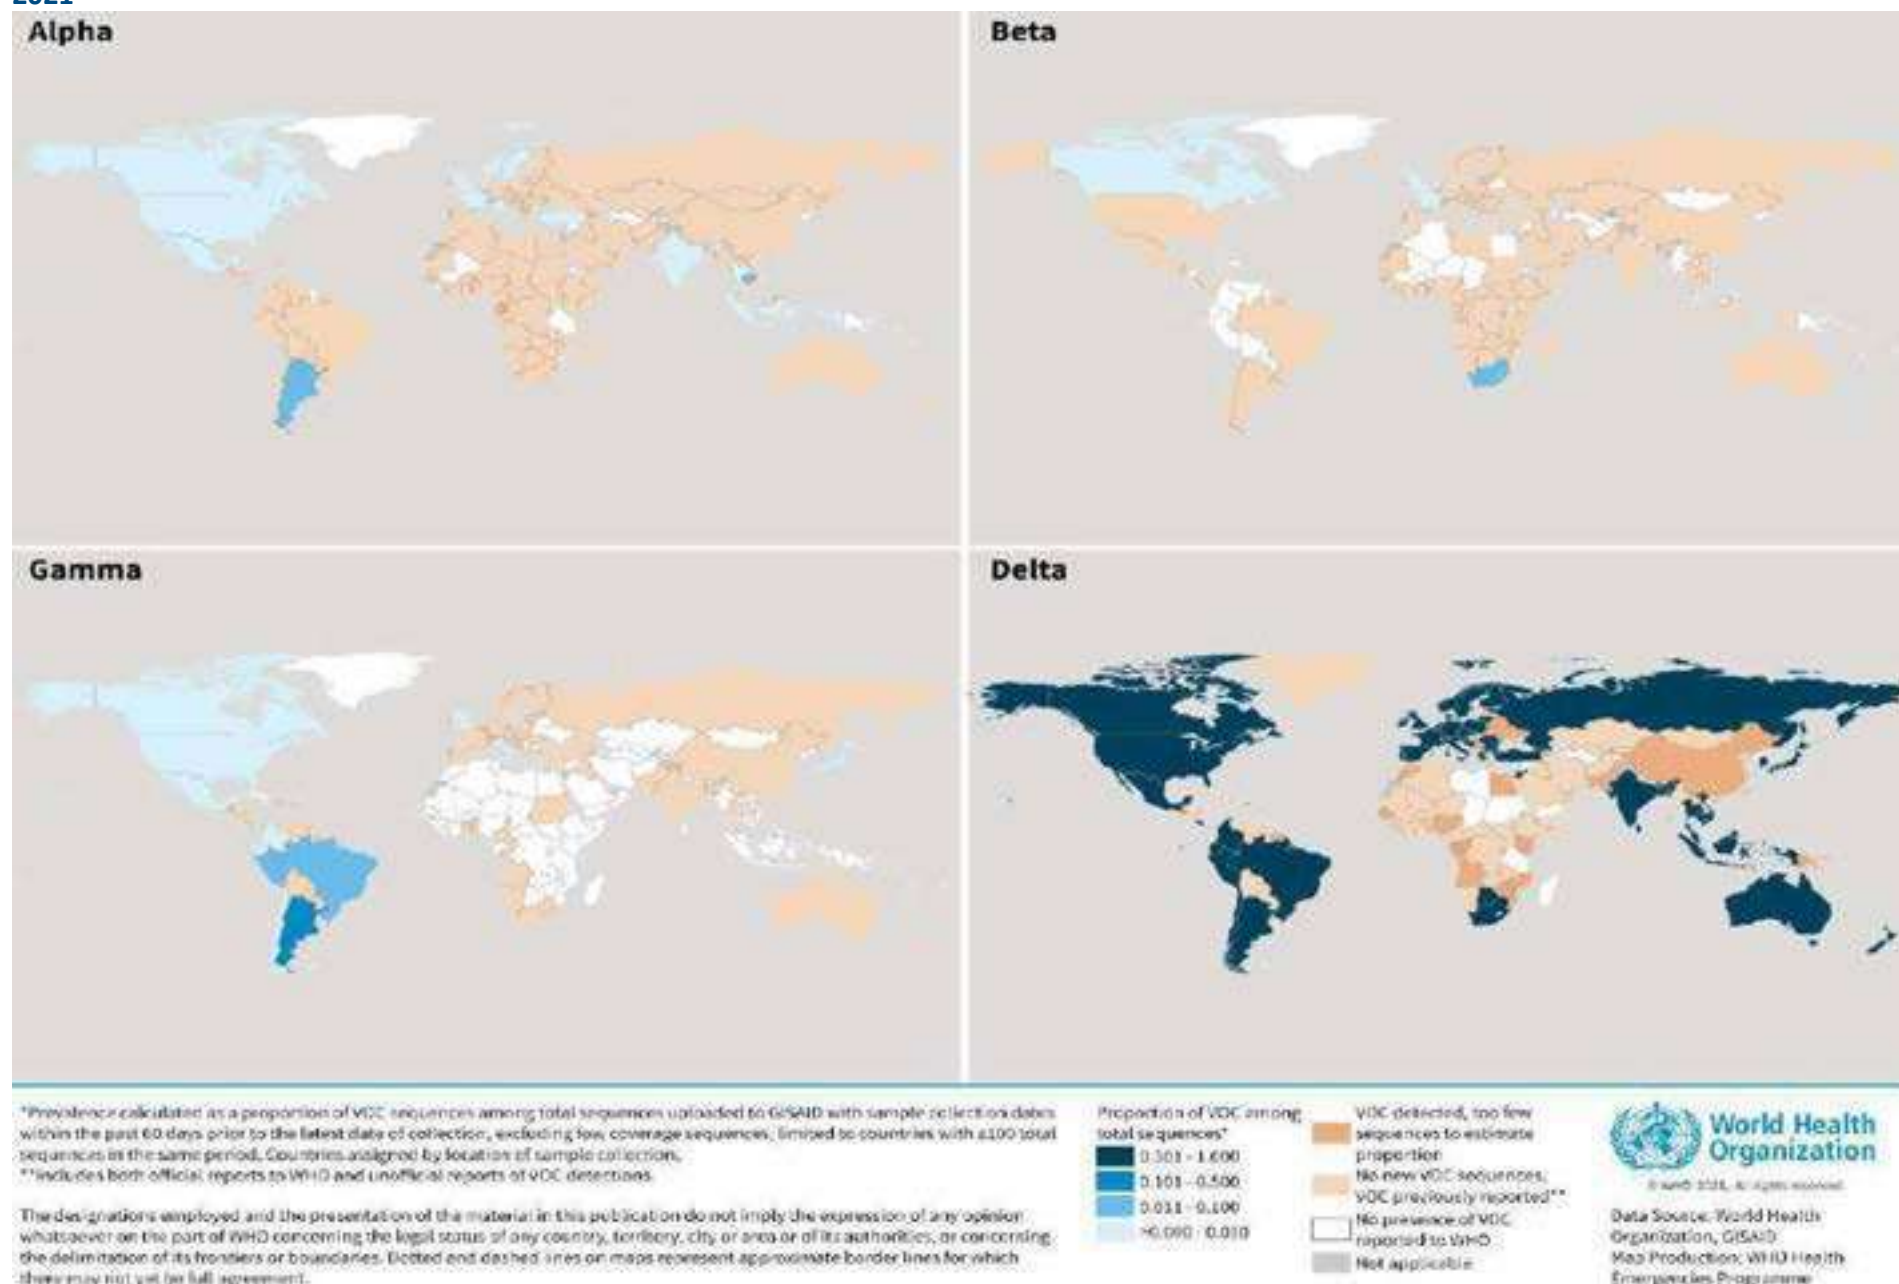

The current global epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, with the prevalence of other variants continuing to decline among genomic sequences submitted to publicly available datasets or detections reported to WHO (Figure 4, Annex 2). Delta has outcompeted other variants, including other VOCs, in most countries. Omicron, which was only identified recently, has been reported in a limited number of countries so far (Figure 5). At present, there is evidence of spread to several countries in four WHO regions. While most of the cases identified in these countries are travel-related, this may change as more information becomes available. Of 839 119 sequences uploaded to [GISAID](#) with specimens collected in the last 60 daysⁱ, 837 253 (99.8%) were Delta, 314 (<0.1%) Gamma, 160 (<0.1%) Alpha, 159 (<0.1%) Omicron, 14 (<0.1%) Beta, and <0.1% comprised other circulating variants (including VOIs Mu and Lambda).

Sub-regional and country-level variation continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual, and other variants (e.g., Gamma, Lambda, Mu) still contribute a large proportion of reported sequences. South Africa, where Omicron was first detected, has experienced a recent sharp increase in the number of cases in multiple provinces, coinciding with the detection of the Omicron variant.

To note, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

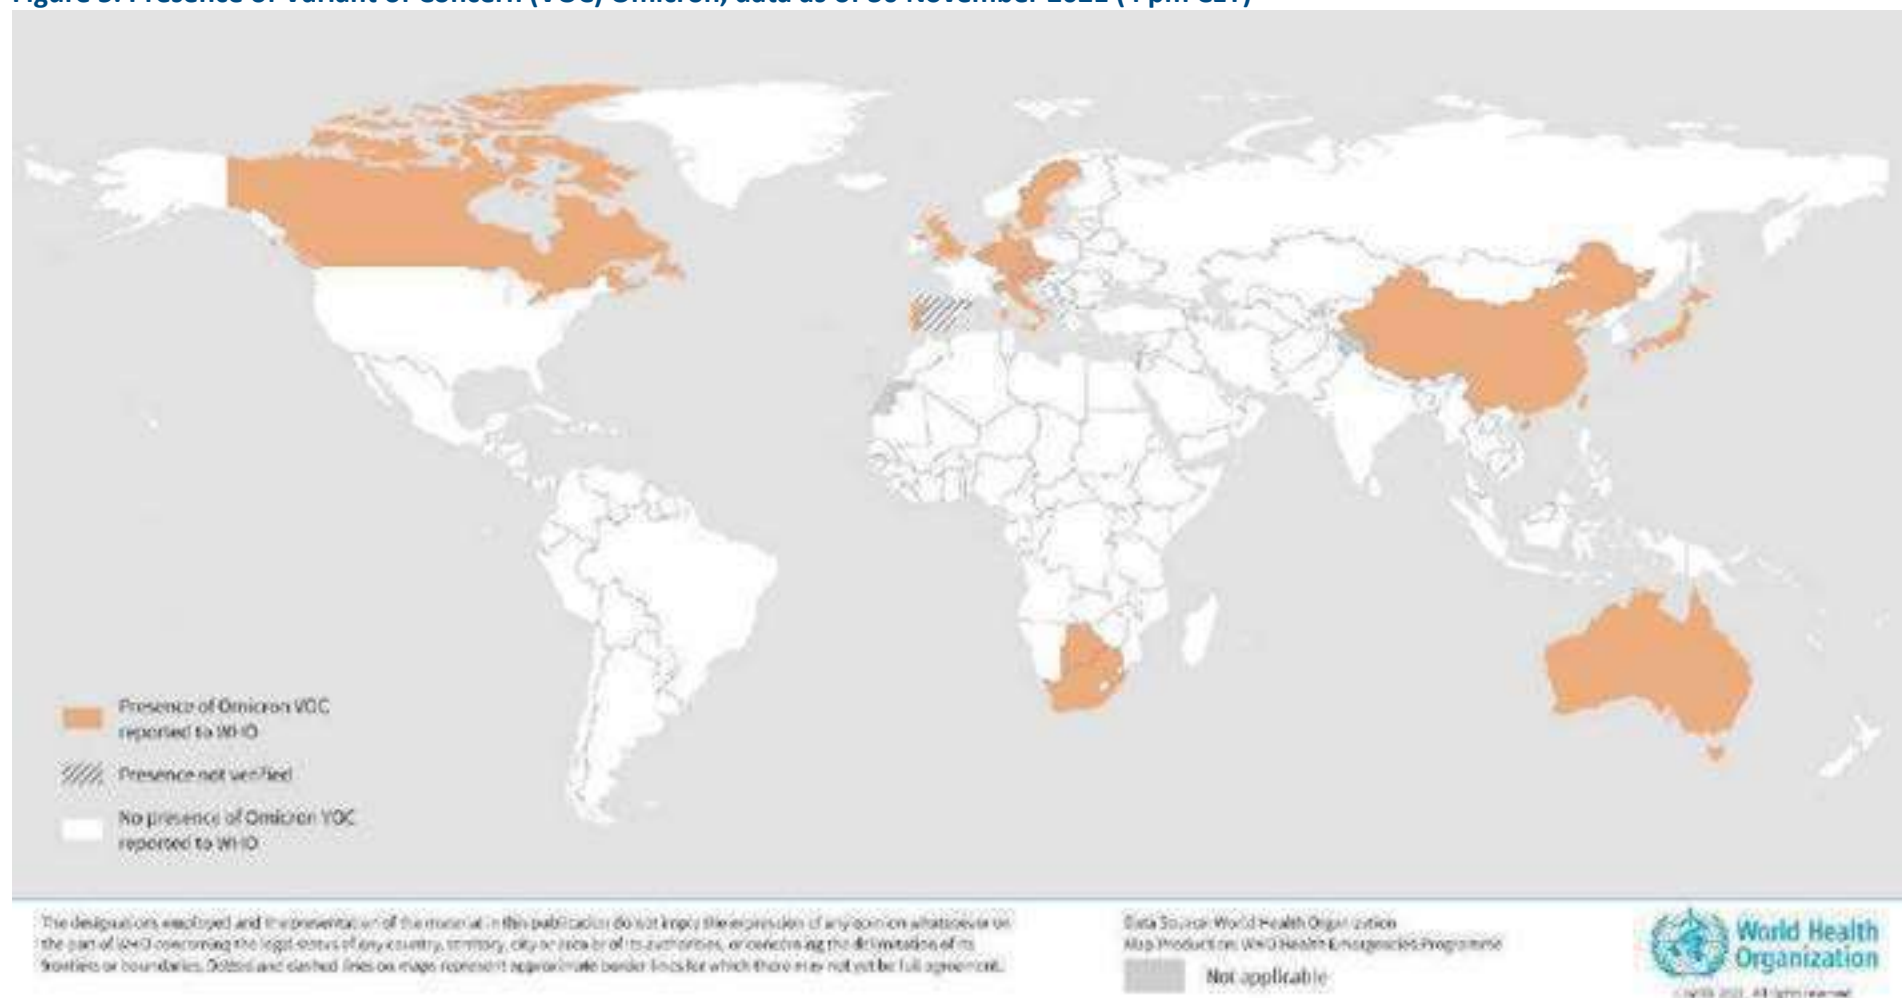

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 29 September to 28 November 2021 (last reported sample at the time of data extraction), excluding low coverage sequences.

Figure 4. Prevalence of Variants of Concern (VOCs) Alpha, Beta, Gamma and Delta in the last 60 days and historic detections, data as of 30 November 2021

Prevalence data based on sequences reported to [GISAID](#), excluding low coverage sequences. See also [Annex 2](#) for reported VOC detections by country/territory/area

Figure 5. Presence of Variant of Concern (VOC) Omicron, data as of 30 November 2021 (4 pm CET)

Presence of Omicron variant is based on information reported to WHO. It includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). See also [Annex 2](#) for reported VOC detections by country/territory/area.

Phenotypic characteristics

Available evidence on the phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the [last detailed update on 16 November](#), there are several new publications on the phenotypic characteristics of VOCs.

A retrospective cohort study (not yet peer-reviewed)¹ was conducted in the city of Belo Horizonte, Brazil to evaluate the impact of the Gamma variant on hospital admissions and mortality. The Gamma variant became the dominant variant in the country from January 2021 following its emergence in Amazonas state in December 2020. The socio-demographics varied widely across the country and prior to the arrival of the Gamma variant; mortality was less likely among those admitted to hospitals in the city as compared to those admitted to hospitals in rural areas. A total of 42 443 patients who tested positive for SARS-CoV-2 by RT-PCR between 13 March 2020 and 9 September 2021 were included in the study. Using multivariable logistic regression analysis adjusting for covariates such as gender, ethnicity, age, socioeconomic status, comorbidities and severity of symptoms, the in-hospital mortality between periods was compared, there was no difference when comparing the first period, 13 March 2020 – 18 October 2020, to the second period, 19 October 2020 – 14 February 2021, (OR=1.08, 95%CI 0.98-1.19, p=0.117). However, in-hospital mortality was higher during the third period 15 February 2021 – 9 September 2021 (OR=1.95, 95%CI=1.79-2.11, p<0.001) as compared to the first. This suggests that mortality was higher during periods of transmission of the Gamma variant however, it is unknown whether this is due to a more pathogenic effect of the virus or as a result of the increased pressure on the healthcare system.

A peer-reviewed retrospective study conducted in Israel² between February 2020 and October 2021 examined the trends in COVID-19 incidence, morbidity and mortality. A fourth surge in case incidence across the country, reported in Israel from June to September 2021, was driven by the Delta variant and characterized by the country's highest rate of infection, with over 11 000 cases per day; the number of severe hospitalizations due to COVID-19 during the fourth period was lower as compared to those reported during the previous three surges (e.g., maximum 8 per 100 000 population in the fourth surge vs. maximum 16 per 100 000 population during the second surge). During the fourth surge, higher death rates were reported among people who were not fully vaccinated as compared to those who were fully vaccinated (0.1 deaths per 100 000 population in fully vaccinated individuals vs. over 0.7 deaths per 100 000 population in partially vaccinated individuals). Most public health and social measures were lifted in April and May 2021, which may have contributed to higher transmission during the fourth surge. Authors inferred that reduced hospitalizations and mortality in the fourth surge compared to the previous waves likely reflect higher vaccine coverage.

A study (not yet peer-reviewed) to assess markers of viral shedding, was conducted by the United States Centers for Disease Control and Prevention (US CDC)³, among 95 prisoners with different vaccination status (82% fully vaccinated, 16% unvaccinated and 2% partially vaccinated), during an outbreak of the Delta variant in a federal prison (18 July-9 August 2021). A small number of participants (3% of fully vaccinated and 12% of not fully vaccinated), had a documented prior SARS-CoV-2 infection. Among individuals with no known history of infection, there was no difference in the median duration of RT-PCR positivity between those fully vaccinated and not fully vaccinated (13 days; p=0.50). The median duration of illness among those with a known history of prior infection regardless of their vaccination status was shorter, 10 days, but with no evidence of a difference as compared to those without previous infection (p=0.12). No difference was found in the median duration of RT-PCR positivity by type of vaccine received (13 days; p=0.39). Similarly, there was no difference in the duration of viral culture positivity between those fully and not fully vaccinated (median of 5 days for both groups). Finally, there was no evidence of a difference in Ct value by vaccination status, type of vaccine, time since vaccination or known prior infection (p>0.0026, the Bonferroni-corrected α threshold).

A published study conducted by the US CDC⁴, compared the odds of having laboratory-confirmed COVID-19 between unvaccinated adult patients (≥18 years) with a previous SARS-CoV-2 infection occurring 90–179 days prior to hospitalization, and patients who were fully vaccinated with an mRNA COVID-19 vaccine 90–179 days before hospitalization with no previous documented SARS-CoV-2 infection. Patients were included in the study if they had been tested at least twice: once associated with a COVID-19-like illness hospitalization during the study period (1 January– 2 September 2021) and at least once earlier (between February 1, 2020, and ≥14 days prior to the current admission). Among the 201 269 hospitalized with a COVID-19-like illness, 7348 met the study inclusion criteria of whom 1020 were previously infected and unvaccinated, and 6328, fully vaccinated and previously uninfected. In a multivariable logistic regression, the adjusted odds of laboratory confirmed COVID-19 was 5.49 times higher (95%CI 2.75-10.99) among those who were unvaccinated with previous infection compared to those who were fully vaccinated with no previous infection. These findings suggest that vaccine-induced immunity provides greater protection than infection-induced immunity against laboratory-confirmed COVID-19.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta	Omicron
Transmissibility	Increased transmissibility ⁵	Increased transmissibility ^{6,7}	Increased transmissibility ^{7,8}	Increased transmissibility ^{7,9,10}	No direct evidence for increased transmissibility.
Disease severity	Possible increased risk of hospitalization ^{11,12} , possible increased risk of severe disease and death ^{13,14}	Possible increased risk of hospitalization ¹² , possible increased in-hospital mortality ¹⁵	Possible increased risk of hospitalization ¹² , possible increased risk of severe disease ¹⁶	Possible increased risk of hospitalization ^{17,18}	Not yet known. Clinical outcome data are under review.
Risk of reinfection	Neutralizing activity retained ¹⁹ , risk of reinfection remains similar ²⁰	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²¹	Moderate reduction in neutralizing activity reported ²²	Reduction in neutralizing activity reported ^{23–25}	Preliminary evidence suggests a possible increased risk of reinfection ²⁶
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ²⁷	No impact on RT-PCR or Ag RDTs observed ²⁵	None reported to date	No impact on RT-PCR or Ag RDTs observed ²⁸	PCR continues to detect Omicron. Impact on Ag-RDTs is under investigation.

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

Table 3 summarizes the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to non-VOC settings. As of the writing of this update, no studies of neutralization or vaccine performance against Omicron are available. Since the [16 November update](#), six notable new studies have provided evidence of COVID-19 vaccine performance against the other Variants of Concern.

A peer-reviewed, test-negative case-control study from India evaluated the effectiveness of Bharat-Covaxin, an inactivated whole-virion vaccine, in preventing symptomatic disease among employees of a tertiary care hospital in New Delhi from 15 April 2021 to 15 May 2021, when Delta was the dominant circulating variant.²⁹ The VE of one and two doses of the vaccine at preventing symptomatic disease 14 or more days after vaccination was -1% (95% CI: -51-33%, not statistically significant) and 50% (33-62%), respectively. When excluding persons who had been previously infected with SARS-CoV-2, the VE of two doses of the vaccine was 47% (29-61%) against symptomatic disease among this population with high exposure, with a median follow-up time of 50 days from receipt of the second dose.

A second test-negative case-control study (not yet peer-reviewed) assessed the effectiveness of Sinovac-CoronaVac among 19 838 pregnant women 18-49 years of age in Brazil from 15 March 2021 to 3 October 2021.³⁰ Gamma was the predominant circulating variant during most of this period, while Delta became the predominant circulating variant during the last 1-2 months of the study. The effectiveness of one and two doses of the vaccine at preventing symptomatic disease 14 or more days after vaccination was 5% (-18.2%-23.7%, not statistically significant) and 41% (27.0-52.2%), respectively. The VE of one and two doses against progression to severe disease (defined as dyspnea or respiratory discomfort, persistent pressure or pain in the chest, oxygen saturation less than 95% on room air, cyanosis of the lips or face) or COVID-19 hospitalization or death, among pregnant women infected with SARS-CoV-2, was 67.7% (20.0-87.0) and 85.4% (59.4-94.8%), respectively. The maximum possible follow-up time post final dose was approximately 28 weeks.

A third retrospective cohort study (not yet peer-reviewed) from the United Arab Emirates assessed the VE of the Beijing CNBG- BBIBP-CorV vaccine against hospitalization and death among residents of Abu Dhabi from September 2020 to April 2021. During the study period, there was initially a high prevalence of non-VOCs, followed by a period of Alpha predominance, then a period of Beta predominance at the very end.³¹ Authors note that Alpha and Beta variants comprised the majority of cases over the study period, although the study did not present variant-specific VE estimates. A single dose of Beijing CNBG- BBIBP-CorV vaccine was not effective at preventing hospitalization (VE: -35%, 95% CI: -45 to -26%) and showed low VE against death 14 or more days after vaccination (VE: 12%, 95% CI: -95%-61%, not statistically significant). However, two doses of the vaccine had VE against hospitalization and death of 74% (72-76%) and 96% (69-99%) 14 or more days following immunization. The maximum possible follow-up time post final dose was approximately 33.5 weeks.

A fourth, peer-reviewed retrospective cohort study from Singapore evaluated the combined VE of Moderna-mRNA-1273 and Pfizer BioNTech-Comirnaty vaccines at preventing infection, symptomatic disease, and severe disease among 1204 household contacts of 301 confirmed Delta index cases.³² Two doses of either vaccine was 61.6% (95% CI: 37.5-80.4%), 67.9% (41.3-87.8%), and 100% (no CI available due to no events among vaccinated persons) effective at preventing infection, symptomatic disease, and severe disease, respectively, 15 or more days following receipt of the second dose. Lower VE estimates for infection and symptomatic disease than in other studies likely reflect the high exposure risk among household contacts of cases. In addition, after adjusting for age, gender, and vaccination status of household contacts, vaccinated index cases were less likely to infect household contacts compared to unvaccinated contacts, though this finding was not statistically significant (VE against transmission: 27%, 95% CI: -40-62%).

A fifth prospective cohort study from the United Kingdom (not yet peer-reviewed) evaluated the VE of AstraZeneca-Vaxzevria and Pfizer BioNTech-Comirnaty against transmission of SARS-CoV-2 infection to household contacts of Alpha index cases and Delta index cases, separately.³³ After adjusting for age and vaccination status of contacts, two doses of AstraZeneca-Vaxzevria or Pfizer BioNTech-Comirnaty vaccines were 35% (95% CI:-26%-74%, not statistically significant) and 57% (5-85%) effective at preventing transmission to household contacts of Alpha index cases, respectively, and 42% (14-69) and 31% (-3-61%, not statistically significant) effective at preventing transmission to household contacts of Delta index cases, respectively.

Finally, a test-negative case-control study from the United Kingdom (not yet peer-reviewed) assessed the VE of a third dose of Pfizer BioNTech-Comirnaty in addition to the primary series of either two doses of AstraZeneca-Vaxzevria or two doses of Pfizer BioNTech-Comirnaty among persons 50 years and older during a period when Delta was the dominant variant.³⁴ Compared to persons receiving two doses of AstraZeneca-Vaxzevria 140 or more days prior to testing with no booster, the relative VE of two doses of AstraZeneca-Vaxzevria plus an additional dose of Pfizer BioNTech-Comirnaty was 87.4% (84.9-89.4%) against symptomatic disease 14 or more days after the additional dose. The relative VE against symptomatic disease of a third dose of Pfizer BioNTech-Comirnaty following a primary series of Pfizer BioNTech-Comirnaty compared to two doses of Pfizer BioNTech-Comirnaty only was 84.4% (82.8%-85.8%). Using the unvaccinated group as the comparator, the absolute VE of a third dose of Pfizer BioNTech-Comirnaty following a primary series of AstraZeneca-Vaxzevria was 93.1% (91.7-94.3%); the absolute VE of three doses of Pfizer BioNTech-Comirnaty was 94.0% (93.4-94.6%).

Omicron														

VE refers to vaccine effectiveness and vaccine efficacy. *Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the [VIEW-hub Resources Library](#). References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table. Information for the Omicron variant will be included in upcoming issues as data becomes available.

African Region

Following a declining trend since late June 2021, the case incidence in the African Region increased by 93%, with over 43 000 new cases reported during the week of 22-28 November. To note, 43% of the new cases were from a batch reporting of antigen tests from South Africa in the last week. Twenty-one of the 49 countries in the region (43%) reported an increase of >10% in new cases as compared to the previous week, with the highest numbers of new cases reported from South Africa (29 373 new cases; 49.5 new cases per 100 000 population; an 740% increase), Mauritius (3474 new cases; 273.2 new cases per 100 000; a 63% decrease) and Réunion (1875 new cases; 209.4 new cases per 100 000; a 43% increase).

Eleven of the 49 countries reported an increase of over 10% in the number of new weekly deaths with the highest numbers of new deaths reported from South Africa (219 new deaths; <1 new death per 100 000 population; a 128% increase), Ethiopia (64 new deaths; <1 new death per 100 000; an 8% increase), and Mauritius (50 new deaths; 3.9 new deaths per 100 000; a 52% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported a 24% decline in case incidence in the last week, with over 659 000 new cases reported. This trend is largely driven by the 31% decrease in the incidence of cases in the United States of America despite the country continuing to report the highest number of cases (464 800 new cases; 140.4 new cases per 100 000) in the region. It is important to note that the public holiday in the United States of America which took place at the end of last week may have impacted testing and reporting. Twenty-seven percent (15/56) of countries in the region reported increases of over 10%. In addition to the United States of America, countries reporting the highest numbers of cases included Brazil (64 313 new cases; 30.3 new cases per 100 000; similar to the previous week's figures) and Canada (19 737 new cases; 52.3 new cases per 100 000; a 16% increase).

The incidence of deaths also declined with just under 9400 new deaths reported, a 36% decrease compared to the previous week. Despite having the highest number of deaths in the Region, the United States of America and Brazil saw reductions in the number of new deaths (5003 new deaths; 1.5 new deaths per 100 000; a 52% decrease and 1587 new deaths; <1 new death per 100 000; a 16% decrease, respectively), as compared to the numbers reported in the previous week.

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The weekly incidence of cases in the Eastern Mediterranean Region remained stable with over 94 000 reported (similar to the previous week's figures). The number of weekly deaths decreased by 8%, with just over 1700 reported. However, nearly one-third (7/22) of countries in the region reported >10% increase in weekly incidence, the highest including Sudan (143%), Tunisia (80%) and Lebanon (69%). The highest numbers of new cases were reported from the Islamic Republic of Iran which contributed to just over a third of the cases in the region (32 003 new cases; 38.1 new cases per 100 000; a 23% decrease), followed by Jordan (28 023 new cases; 274.7 new cases per 100 000; a 30% increase), and Lebanon (9401 new cases; 137.7 new cases per 100 000; a 69% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (697 new deaths; <1 new death per 100 000; a 14% decrease), Egypt (433 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Jordan (168 new deaths; 1.6 new deaths per 100 000; a 27% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region has continued to report an increase in cases since early-October 2021, with over 2.6 million new cases reported this week (a 7% increase as compared to the previous week). The incidence in deaths has remained stable compared to the previous week, with over 29 000 new deaths reported. Thirty-eight percent of countries in the region (23/61) reported an increase in new weekly cases of over 10%. Just over a third of all new cases continue to be reported from three countries: Germany (406 754 new cases; 489.1 new cases per 100 000; a 22% increase), the United Kingdom (304 374 new cases; 448.4 new cases per 100 000; an 8% increase), and the Russian Federation (239 215 new cases; 163.9 new cases per 100 000; an 8% decrease).

The highest numbers of new deaths were reported from the Russian Federation (8660 new deaths; 5.9 new deaths per 100 000; similar to the previous week's figures); Ukraine (3845 new deaths; 8.8 new deaths per 100 000; a 16% decrease) and Poland (2214 new deaths; 5.8 new deaths per 100 000; a 13% increase).

Updates from the [European Region](#)

South-East Asia Region

Since July 2021, the incidence of cases in the South-East Asia Region has continued to decline with 120 000 new cases reported this week, an 11% decrease as compared to the previous week. However, three countries reported an increase of over 10% including Sri Lanka (16%), Bhutan (14%) and Bangladesh (7%). Sri Lanka also reported the third highest number of new cases (5894 new cases; 27.5 new cases per 100 000; a 16% increase), after India (62 110 new cases; 4.5 new cases per 100 000; a 15% decrease) and Thailand (42 232 new cases; 60.5 new cases per 100 000; a 9% decrease).

The number of weekly deaths increased by 26% as compared to the previous week, with over 3500 new deaths reported this week. Three countries reported an increase of >10% including Nepal (27 new deaths; <1 new death per 100 000; a 42% increase); India (2892 new deaths; <1 new death per 100 000; a 36% increase) and Sri Lanka (178 new deaths; <1 new death per 100 000; a 35% increase). Thailand reported the second highest number of deaths after India but the number of deaths declined (320 new deaths; <1 new death per 100 000; a 9% decrease) as compared to the previous week.

Updates from the [South-East Asia Region](#)

Western Pacific Region

Following a relatively stable trend over the past month, the weekly case incidence in the Western Pacific Region increased by 24% this week with over 220 000 new cases reported. Six of the 27 countries in the region reported an increase in case incidence of >10%, including the Northern Mariana Islands (222%), Viet Nam (70%), Brunei Darussalam (40%), the Republic of Korea (28%), Australia (15%) and Lao People's Democratic Republic (13%). The highest number of new cases continued to be reported from Viet Nam (112 779 new cases; 115.9 new cases per 100 000; a 70% increase), Malaysia (37 830 new cases; 116.9 new cases per 100 000; a 7% decrease) and the Republic of Korea (25 466 new cases; 49.7 new cases per 100 000; a 28% increase).

The region reported over 3100 new deaths this week, similar to the previous week's figures. The highest numbers of new deaths continued to be reported from the Philippines (1302 new deaths; 1.2 new death per 100 000; a 20% decrease), Viet Nam (1007 new deaths; 1.0 new deaths per 100 000; a 51% increase), and Malaysia (302 new deaths; <1 new death per 100 000; a 13% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 30 November, highlights include the following:

- Ethiopia launches a nationwide COVID-19 vaccination campaign
- Training for Indigenous youth leaders to promote COVID-19 messaging in Colombia
- Addressing the urgent COVID-19 and broader health needs of vulnerable populations in Belarus through a WHO support mission
- Maintaining essential health services during COVID-19 in Afghanistan
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies

Annexes

Annex 1. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. Likewise, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.

*Newly reported in this update. indicates that information for this variant was received by WHO from official sources. indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 3: Data, table, and figure notes](#)

Annex 3. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

‘Countries’ may refer to countries, territories, areas or other jurisdictions of similar status. The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers’ products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 67, published 23 November 2021

In this edition:

- [Global overview](#)
- [Special focus: Points of entry, international travel and transport in the context of the COVID-19 pandemic](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 21 November 2021

Globally, weekly case incidence has continued to increase for more than one month, with just under 3.6 million confirmed new cases reported during the week of 15-21 November 2021, a 6% increase as compared to the previous week. Similarly, new weekly deaths increased by 6% in the past seven days as compared to the previous week, with over 51 000 new deaths reported. As of 21 November, over 256 million confirmed cases and over 5.1 million deaths have been reported globally.

The European Region reported an 11% increase in new weekly cases, while the South-East Asia and the Eastern Mediterranean Regions reported decreases of 11% and 9% respectively; the other regions reported similar weekly case incidences as compared to the previous week. While the Western Pacific Region and the Region of the Americas reported relatively stable case incidence, both regions reported large increases in new weekly deaths, 29% and 19% respectively. In contrast, the African and the South-East Asia Regions reported a decrease in new weekly deaths, while the other regions reported a similar trend as compared to the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 21 November 2021**

**See [Annex 2: Data, table, and figure notes](#)

The regions reporting the highest weekly case incidence per 100 000 population continue to be the European Region (260.2 new cases per 100 000 population) and the Region of the Americas (73.6 new cases per 100 000 population); these regions also reported the highest weekly incidence in deaths, of 3.2 and 1.3 per 100 000 population, respectively.

The highest numbers of new cases were reported from the United States of America (558 538 new cases; similar to the previous week's figures), Germany (333 473 new cases; a 31% increase), the United Kingdom (281 063 new cases; an 11% increase), the Russian Federation (260 484 new cases; similar to the previous week's figures) and Turkey (163 835 new cases; a 9% decrease).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 21 November 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 427 657 (67%)	11%	83 419 825 (33%)	29 465 (57%)	3%	1 510 654 (29%)
Americas	753 140 (21%)	0%	95 847 458 (37%)	13 603 (26%)	19%	2 334 373 (45%)
Western Pacific	174 797 (5%)	0%	9 947 215 (4%)	3 161 (6%)	29%	137 793 (3%)
South-East Asia	136 120 (4%)	-11%	44 409 237 (17%)	2 842 (6%)	-19%	702 762 (14%)
Eastern Mediterranean	92 520 (3%)	-9%	16 657 029 (6%)	1 917 (4%)	-4%	307 333 (6%)
Africa	13 164 (0%)	-4%	6 198 494 (2%)	385 (1%)	-30%	152 074 (3%)
Global	3 597 398 (100%)	6%	256 480 022 (100%)	51 373 (100%)	6%	5 145 002 (100%)

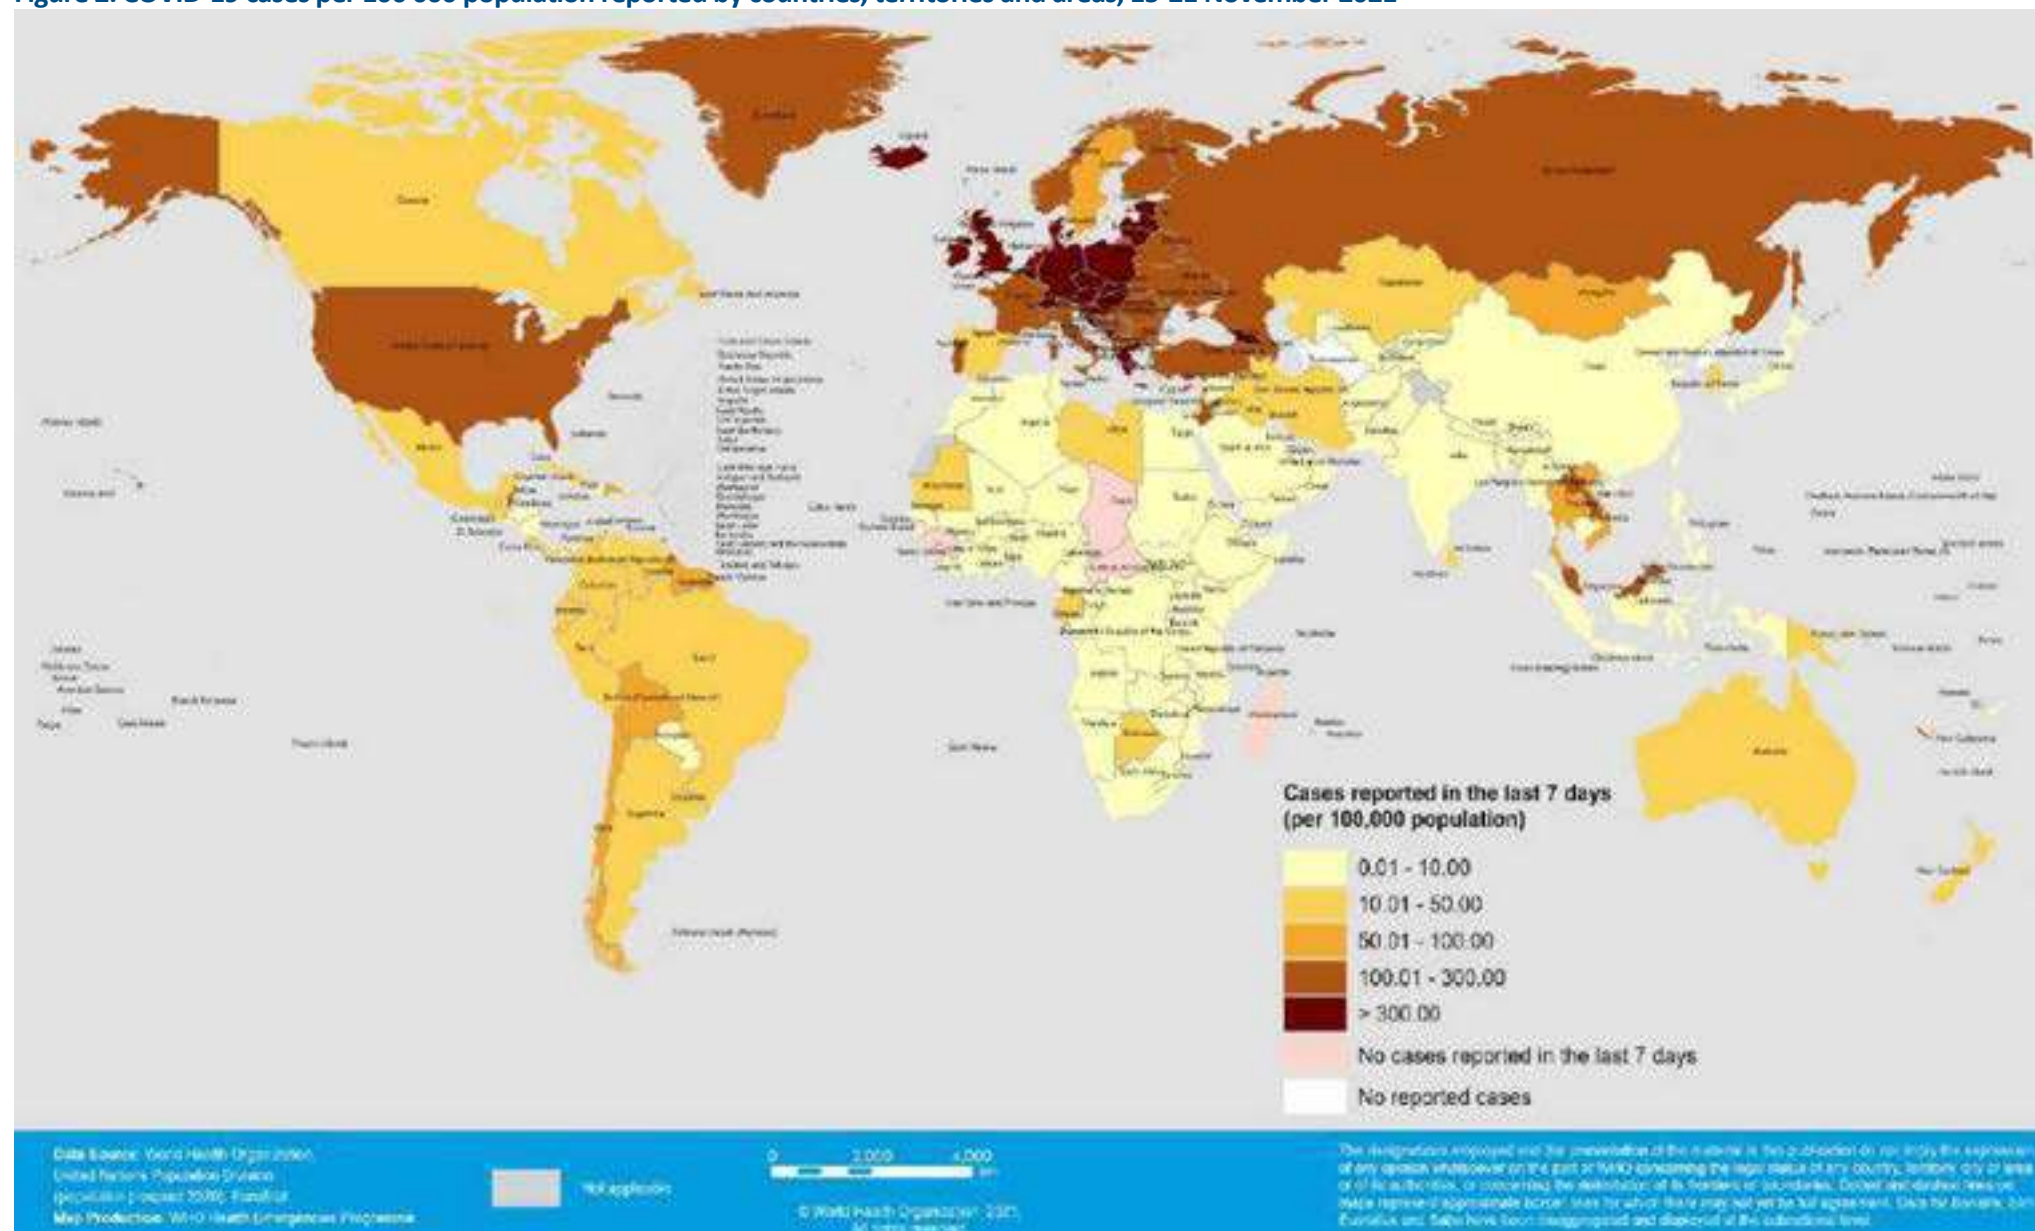

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

Special Focus: Points of entry, international travel and transport in the context of the COVID-19 pandemic

Since the characterization of the COVID-19 outbreak as a pandemic in March 2020, international travel and transport, as well as related sectors such as tourism, have been substantially impacted. For example, the United Nations World Tourism Organization (UNWTO) estimates that around 100 million jobs directly related to tourism are at risk as a result of the impact of the pandemic on the sector. According to the International Civil Aviation Organization (ICAO)'s latest economic impact analysis, despite a moderate increase in domestic passenger air travel in 2021 (up to 17% more passengers) as compared to 2020, it is estimated that there will still be up to 73% fewer international passengers in 2021 as compared to 2019. This decrease in travel translates to approximately USD 250-252 billion loss of gross operating revenues from international passenger air travel in 2021¹ with ongoing losses predicted to occur in 2022, particularly in the international air travel industry.²

The pandemic also continues to have severe repercussions for the maritime sector, seafarers in particular, many of whom continue to be denied access to medical care in ports, remain stranded on ships unable to be repatriated at the end of their contract, and encounter substantial challenges to receive COVID-19 vaccines or meet the vaccine-related entry requirements of different countries.³ [WHO recommends](#) that in establishing policies on essential travel, governments should consider situations such as emergencies and humanitarian actions (e.g., emergency medical flights and medical evacuations); travel of essential personnel including emergency responders, providers of public health technical support, and critical personnel in the transport and security sectors (e.g., seafarers); and cargo transport for essential supplies such as food, medicines and fuel. Such considerations would help mitigate the current challenges faced by these particular areas so far in the pandemic.

Overview of travel-related health measures

Under the International Health Regulations (IHR) (2005), a State Party implementing strengthened health measures on the basis of a risk to public health that significantly interferes with international traffic, shall share that information with WHO and provide the public health rationale and relevant scientific information for it. Since 6 February 2020, WHO, through its Regional Offices, has collected and shared information on strengthened health measures for 194 out of 196 State Parties on a weekly basis, publishing more than 82 updates on the Event Information Site (EIS), which is the secured platform through which WHO shares information with national focal points and other stakeholders.

Since the beginning of 2021, countries have gradually reopened their borders for international travel: at least 74 countries accept incoming travelers who present either proof of COVID-19 vaccination, a negative PCR test within a given timeframe, or proof of previous SARS-CoV-2 infection. Additionally, 121 countries require proof of a negative PCR or a rapid antigen test before departure regardless of the vaccination status, while 93 countries perform testing upon arrival and 131 countries require isolation or quarantine of some or all travelers. The cost of these measures is generally charged to the traveler, which is counter to the recommendations issued by the Director-General following the [ninth meeting of the IHR Emergency Committee](#) on 26 October 2021, given that this may be economically restrictive for many.

While at least 53 countries have recently reduced the duration of quarantine or testing requirements for vaccinated travelers, 22 countries require vaccination for entry, with limited exceptions for nationals or travelers with proof of previous SARS-CoV-2 infection. Vaccination-based entry requirements do not align with Article 42 of the IHR (2005), which advises that measures must be applied in a non-discriminatory manner, as nearly half of the global population have yet to receive one dose of vaccine.⁴ This point was further emphasized by the Director-General during the [ninth meeting of the IHR Emergency Committee](#), which recommended that countries recognize all vaccines that have

received WHO Emergency Use Listing and all vaccine schedules as per SAGE recommendations, including in the context of international travel.

Currently, at least 85 countries are performing regular risk assessments to inform the public health measures taken for international travel, frequently updating and publishing a list of countries at higher risk to which they apply more restrictive quarantine and additional testing measures. Twenty-nine countries still have entry bans for travelers arriving from certain countries affected by SARS-CoV-2 variants of concern despite the dominance of the Delta variant globally.

Latest WHO travel-related guidance

In July 2021, WHO updated its international travel risk-based interim guidance (first issued in December 2020) and published two documents on [policy and technical considerations for implementing a risk-based approach to international travel in the context of COVID-19](#). This guidance aims to support countries in implementing and calibrating their international travel-related measures, adapted to their specific epidemiological, health system and socioeconomic context, to ensure they are proportionate to the public health risk.

Key changes in the updated documents include the following:

- The inclusion of SARS-CoV-2 variants of concern (VOCs) and variants of interest (VOIs) in the risk assessment, and the application of a precautionary approach in the presence of scientific uncertainties.
- The extension of the temporary recommendation issued by the Director-General not to require proof of COVID-19 vaccination as the only pathway to allow entry to or exit from a country, in accordance with the [advice of the IHR Emergency Committee](#).
- Considerations for the application of individualized approaches to calibrate travel-related quarantine and/or testing requirements for travelers who are fully vaccinated or have proof of previous SARS-CoV-2 infection.
- Reiteration that adherence to personal protective measures such as mask use and physical distancing should continue to be respected by all international travelers, both while onboard conveyances and at points of entry and exit.
- Updated body of evidence on the effectiveness and impact of risk mitigation measures applied in the context of international travel during the COVID-19 pandemic.

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Potential Variants of Concern (VOCs), Variants of Interest (VOIs) or Variants Under Monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, with the prevalence of other variants continuing to decline among genomic sequences submitted to publicly available datasets or detections reported to WHO (Figure 4, Annex 1). Delta has outcompeted other variants, including other VOCs, in most countries.

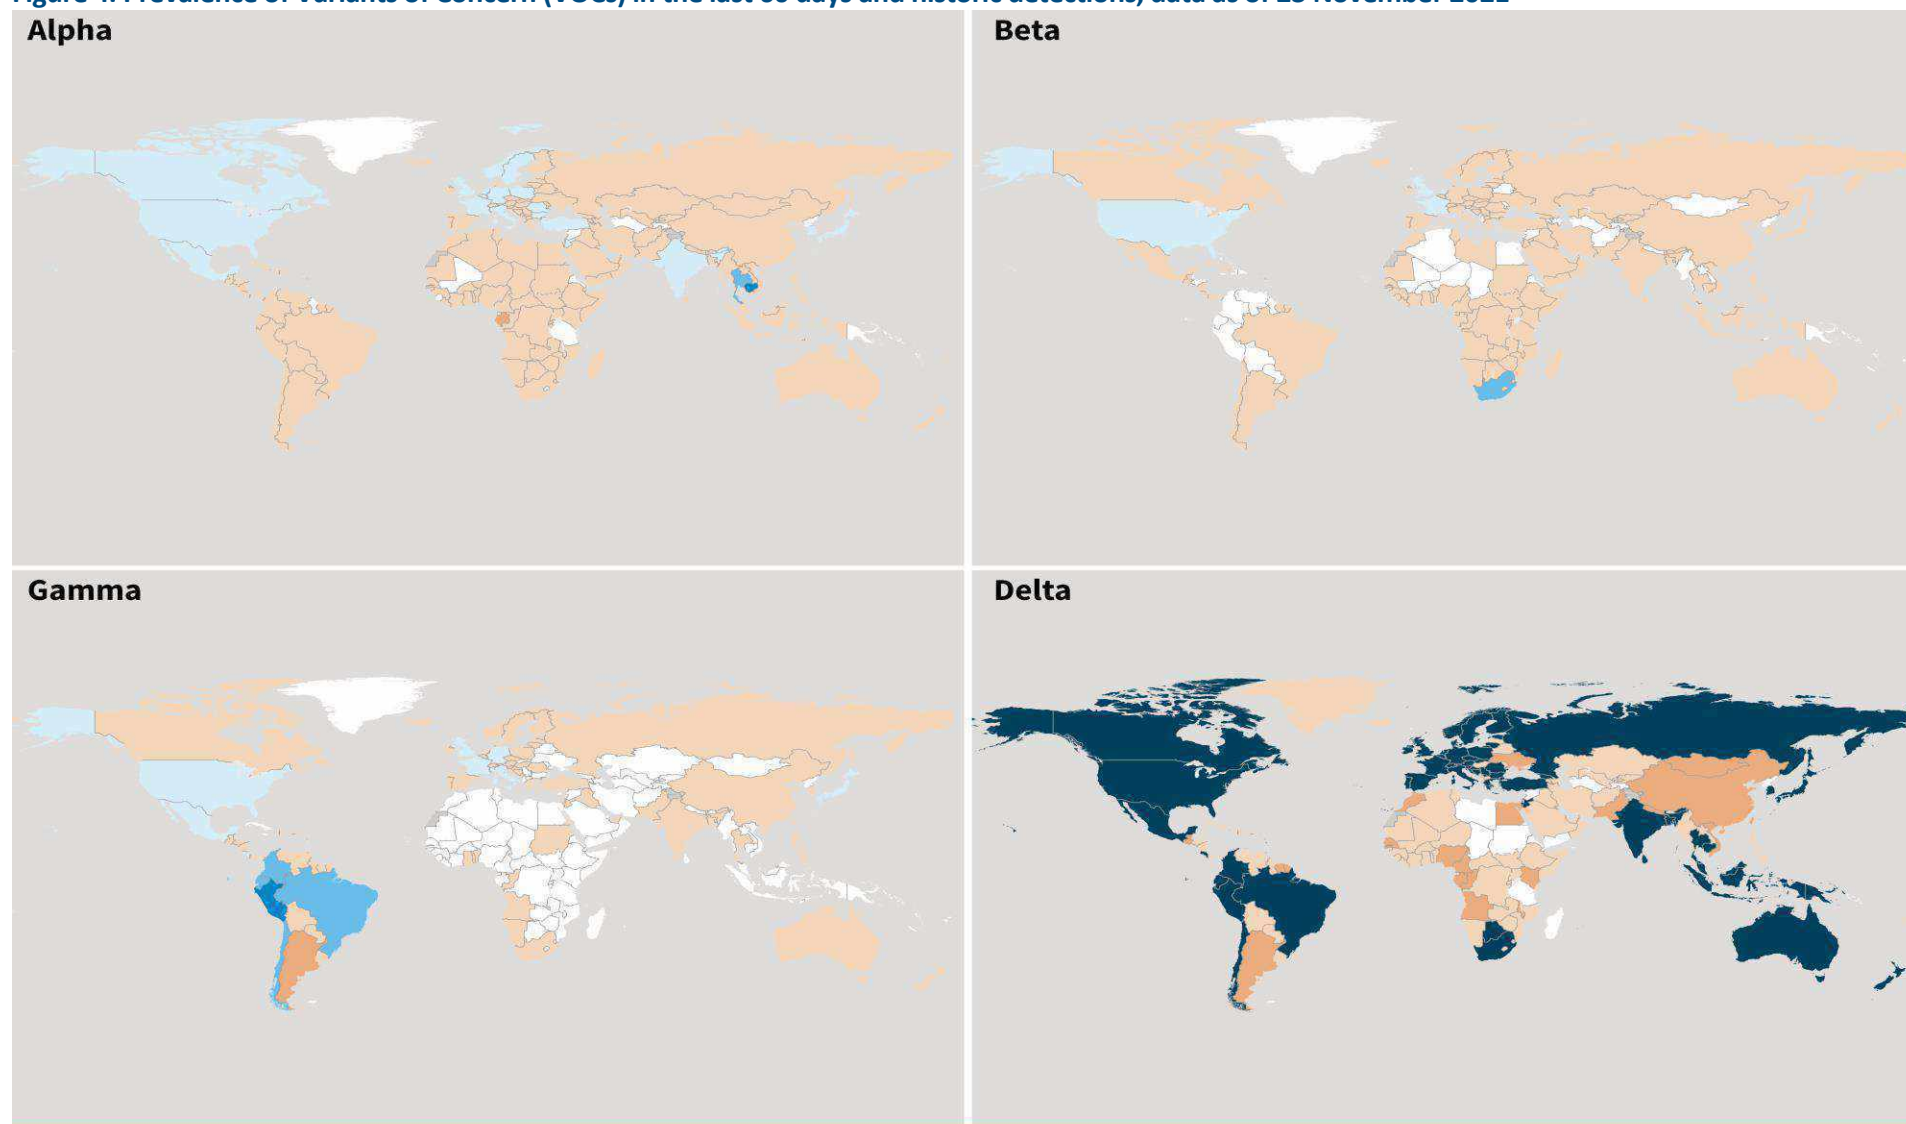

Of 845 087 sequences uploaded to GISAID with specimens collected in the last 60 days¹, 842 992 (99.8%) were Delta, 519 (0.1%) Gamma, 212 (<0.1%) Alpha, 16 (<0.1%) Beta, and 0.1% comprised other circulating variants (including VOIs Mu and Lambda). Sub-regional and country-level variation continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual, and other variants (e.g., Gamma, Lambda, Mu) still contribute a large proportion of reported sequences. Moreover, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

¹ Includes sequences submitted to [GISAID](#) with sample collected dates from 20 September to 19 November 2021 (last reported sample at the time of data extraction), excluding low coverage sequences.

Figure 4. Prevalence of Variants of Concern (VOCs) in the last 60 days and historic detections, data as of 23 November 2021

*Prevalence calculated as a proportion of VOC sequences among total sequences uploaded to GISAID with sample collection dates within the past 60 days prior to the latest date of collection, excluding low coverage sequences, limited to countries with ≥ 100 total sequences in the same period. Countries assigned by location of sample collection.

**Includes both official reports to WHO and unofficial reports of VOC detections.

The designations employed and the presentation of the material in this publication do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement.

Prevalence data based on sequences reported to [GISAID](https://gisaid.org), excluding low coverage sequences. See also [Annex 1](#) for reported VOC detections by country/territory/area

Proportion of VOC among total sequences*

- 0.501 - 1.000
- 0.101 - 0.500
- 0.011 - 0.100
- >0.000 - 0.010

- VOC detected, too few sequences to estimate proportion
- No new VOC sequences, VOC previously reported**
- No presence of VOC reported to WHO
- Not applicable

African Region

Following a decline since late June 2021, the case incidence in the African Region appears to have stabilized in the past two weeks, with over 13 000 new cases reported during the week of 15-21 November. However, 14 of the 49 countries in the Region (29%) reported an increase of >10% in new cases as compared to the previous week, with the highest numbers of new cases reported from South Africa (3498 new cases; 5.9 new cases per 100 000 population; an 82% increase), Ethiopia (1408 new cases; 1.2 new cases per 100 000; an 11% decrease), and Réunion (1308 new cases; 146.1 new cases per 100 000; a 77% increase).

The Region reported the largest decline (30%) in new weekly deaths, with 385 new deaths reported this week. The majority of countries reported a decrease in weekly deaths; however, an increasing trend was observed in nine countries, with the highest numbers of new deaths reported from South Africa (96 new deaths; <1 new death per 100 000 population; a 39% decrease), Ethiopia (59 new deaths; <1 new death per 100 000; a 28% decrease), and Algeria (38 new deaths; <1 new death per 100 000; a 6% increase).

Updates from the [African Region](#)

Region of the Americas

The case incidence rate in the Region of the Americas has been relatively stable over the past two weeks, with over 753 000 new cases reported this week. Thirty percent (17/56) of countries reported an increase of over 10% in the number of new cases in the past week. The highest numbers of new cases were reported from the United States of America (558 538 new cases; 168.7 new cases per 100 000; similar to the previous week's figures), Brazil (64 121 new cases; 30.2 new cases per 100 000; a 16% decrease), and Canada (17 085 new cases; 45.3 new cases per 100 000; similar to the previous week's figures).

Following a steady decrease since mid-September 2021, the Region reported a 19% increase in the incidence of deaths this week, with over 13 000 new deaths. Twenty-one percent (12/56) of the countries reported an increase of over 10%, with Ecuador reporting the largest proportionate increase (13 100%), followed by Mexico (50%) and Bahamas (50%). The highest numbers were reported from the United States of America (8906 new deaths; 2.7 new deaths per 100 000; a 20% increase), Brazil (1879 new deaths; <1 new death per 100 000; a 31% increase), and Mexico (1015 new deaths; <1 new death per 100 000; a 50% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

Case and death incidence rates in the Eastern Mediterranean Region have continued to decline since mid-July 2021, with over 92 000 new cases and over 1900 new deaths reported, a 9% decrease in cases and a similar number of deaths, as compared to the previous week. Out of the 22 countries in the Region, five, including Djibouti (50%), Afghanistan (49%), Oman (39%), Jordan (35%) and Sudan (34%), reported an increase of over 10% in new cases, in the past week. The highest numbers of new cases were reported from the Islamic Republic of Iran which contributed to nearly half of the cases in the Region (41 523 new cases; 49.4 new cases per 100 000; a 19% decrease), followed by Jordan (21 599 new cases; 211.7 new cases per 100 000; a 35% increase), and Egypt (6487 new cases; 6.3 new cases per 100 000; similar to the previous week's figures).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (810 new deaths; 1.0 new deaths per 100 000; a 7% decrease), Egypt (437 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Iraq (159 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region has continued to show an increase in both cases and deaths since early-October 2021, with over 2.4 million new cases reported (an increase of 11% compared to the previous week) and over 29 000 new deaths reported (similar to previous week's figures). Nearly 40% of countries in the Region (24/61) reported an increase in new cases of over 10%. Just over a third of all new cases are from three countries: Germany (333 473 new cases; 401.0 new cases per 100 000; a 31% increase), the United Kingdom (281 063 new cases; 414.0 new cases per 100 000; an 11% increase), and the Russian Federation (260 484 new cases; 178.5 new cases per 100 000; similar to the previous week's figures).

A quarter of countries in the Region reported an increase in new deaths of more than 10% in the past week, with the greatest change seen in the Faroe Islands (a 150% increase), Denmark (an 88% increase), and Poland (a 76% increase). The countries reporting the highest numbers of new deaths included the Russian Federation (8709 new deaths; 6.0 new deaths per 100 000; similar to the previous week's figures), Ukraine (4567 new deaths; 10.4 new deaths per 100 000; similar to the previous week's figures) and Romania (2002 new deaths; 10.4 new deaths per 100 000; a 15% decrease).

Updates from the [European Region](#)

South-East Asia Region

Since July 2021, the incidence of cases and deaths in the South-East Asia Region continues to decline with 136 000 new cases and 2800 new deaths, decreases of 11% and 19% respectively, as compared to the previous week. Only one country, Bhutan, reported an increase of over 10% in new cases in the past week (7 new cases; <1 new case per 100 000; a 250% increase), whilst the highest numbers of new cases were reported from India (73 106 new cases; 5.3 new cases per 100 000; an 11% decrease), Thailand (46 171 new cases; 66.1 new cases per 100 000; an 8% decrease), and Sri Lanka (5084 new cases; 23.7 new cases per 100 000; a 19% decrease).

The highest numbers of new deaths were reported from India (2132 new deaths; <1 new death per 100 000; a 22% decrease), Thailand (351 new deaths; <1 new death per 100 000; an 8 % decrease), and Sri Lanka (132 new deaths; <1 new death per 100 000; similar to the previous week's figures).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The weekly incidence in cases has been relatively stable over the past one month, with approximately 175 000 new cases reported this week. However, six countries, including the Northern Mariana Islands, Republic of Korea, Papua New Guinea, New Caledonia, Viet Nam and Lao People's Democratic Republic reported an increase of over 10%. The highest number of new cases were reported from Viet Nam (66 279 new cases; 68.1 new cases per 100 000; a 16% increase), Malaysia (40 600 new cases; 125.4 new cases per 100 000; similar to the previous week's figures) and Republic of Korea (19 965 new cases; 38.9 new cases per 100 000; a 29% increase).

The Region reported over 3100 new deaths this week, a 29% increase compared to the previous week. The highest numbers of new deaths were reported from the Philippines (1631 new deaths; 1.5 new death per 100 000; an 58% increase), Viet Nam (667 new deaths; <1 new death per 100 000; a 22% increase), and Malaysia (347 new deaths; 1.1 new deaths per 100 000; a 7% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 23 November, highlights include the following:

- Building capacity to create vaccine demand among health care and frontline community workers in Syria
- WHO Europe supports Serbia's public health laboratory financing system
- The Ministry of Health collaborates with district authorities to reduce COVID-19 transmission and mortality in Vientiane Capital, Lao People's Democratic Republic
- Building capacity of frontline health care workforce on latest COVID-19 clinical management practices in the Eastern Mediterranean Region
- Leadership in Emergencies: Building competencies for effective leadership in all-hazards emergency response
- COVID-19 Intra-Action Review (IAR) Training in Muscat, Oman
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies

Newly reported in this update.* indicates that information for this variant was received by WHO from official sources. indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available. *Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 2: Data, table, and figure notes](#)*

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 66, published 16 November 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 14 November 2021

During the week 8 to 14 November 2021, the increasing trend in new global weekly cases continued, with over 3.3 million new cases reported – a 6% increase as compared to the previous week (Figure 1). The Region of the Americas, the European and the Western Pacific Regions all reported increases in new weekly cases as compared to the previous week, while the other regions reported stable or declining trends (Table 1). Similarly, the European Region reported a 5% increase in new deaths, while the other regions reported stable or declining trends. Globally, just under 50 000 new deaths were reported, similar to the previous week's figures. As of 14 November, over 252 million confirmed cases and over 5 million deaths have been reported.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 14 November 2021**

**See [Annex 3: Data, table, and figure notes](#)

The regions reporting the highest weekly case incidence per 100 000 population were the European Region (230 new cases per 100 000 population) and the Region of the Americas (74.2 new cases per 100 000 population); these same two regions reported the highest weekly incidence in deaths, of 3.0 and 1.3 per 100 000 population, respectively.

The highest numbers of new cases were reported from the United States of America (550 684 new cases; 8% increase), the Russian Federation (275 579 new cases; similar to the previous week's figures), Germany (254 436 new cases; 50% increase), the United Kingdom (252 905 new cases; similar to the previous week's figures), and Turkey (180 167 new cases; 9% decrease).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 14 November 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	2 145 966 (64%)	8%	80 941 615 (32%)	28 304 (57%)	5%	1 480 768 (29%)
Americas	758 669 (23%)	8%	95 089 154 (38%)	12 791 (26%)	-3%	2 320 358 (46%)
Western Pacific	173 930 (5%)	6%	9 772 383 (4%)	2 437 (5%)	-5%	134 617 (3%)
South-East Asia	152 535 (5%)	-3%	44 273 117 (18%)	3 530 (7%)	1%	699 920 (14%)
Eastern Mediterranean	101 743 (3%)	-9%	16 564 274 (7%)	1 974 (4%)	-14%	305 396 (6%)
Africa	13 674 (0%)	-33%	6 185 290 (2%)	548 (1%)	3%	151 689 (3%)
Global	3 346 517 (100%)	6%	252 826 597 (100%)	49 584 (100%)	1%	5 092 761 (100%)

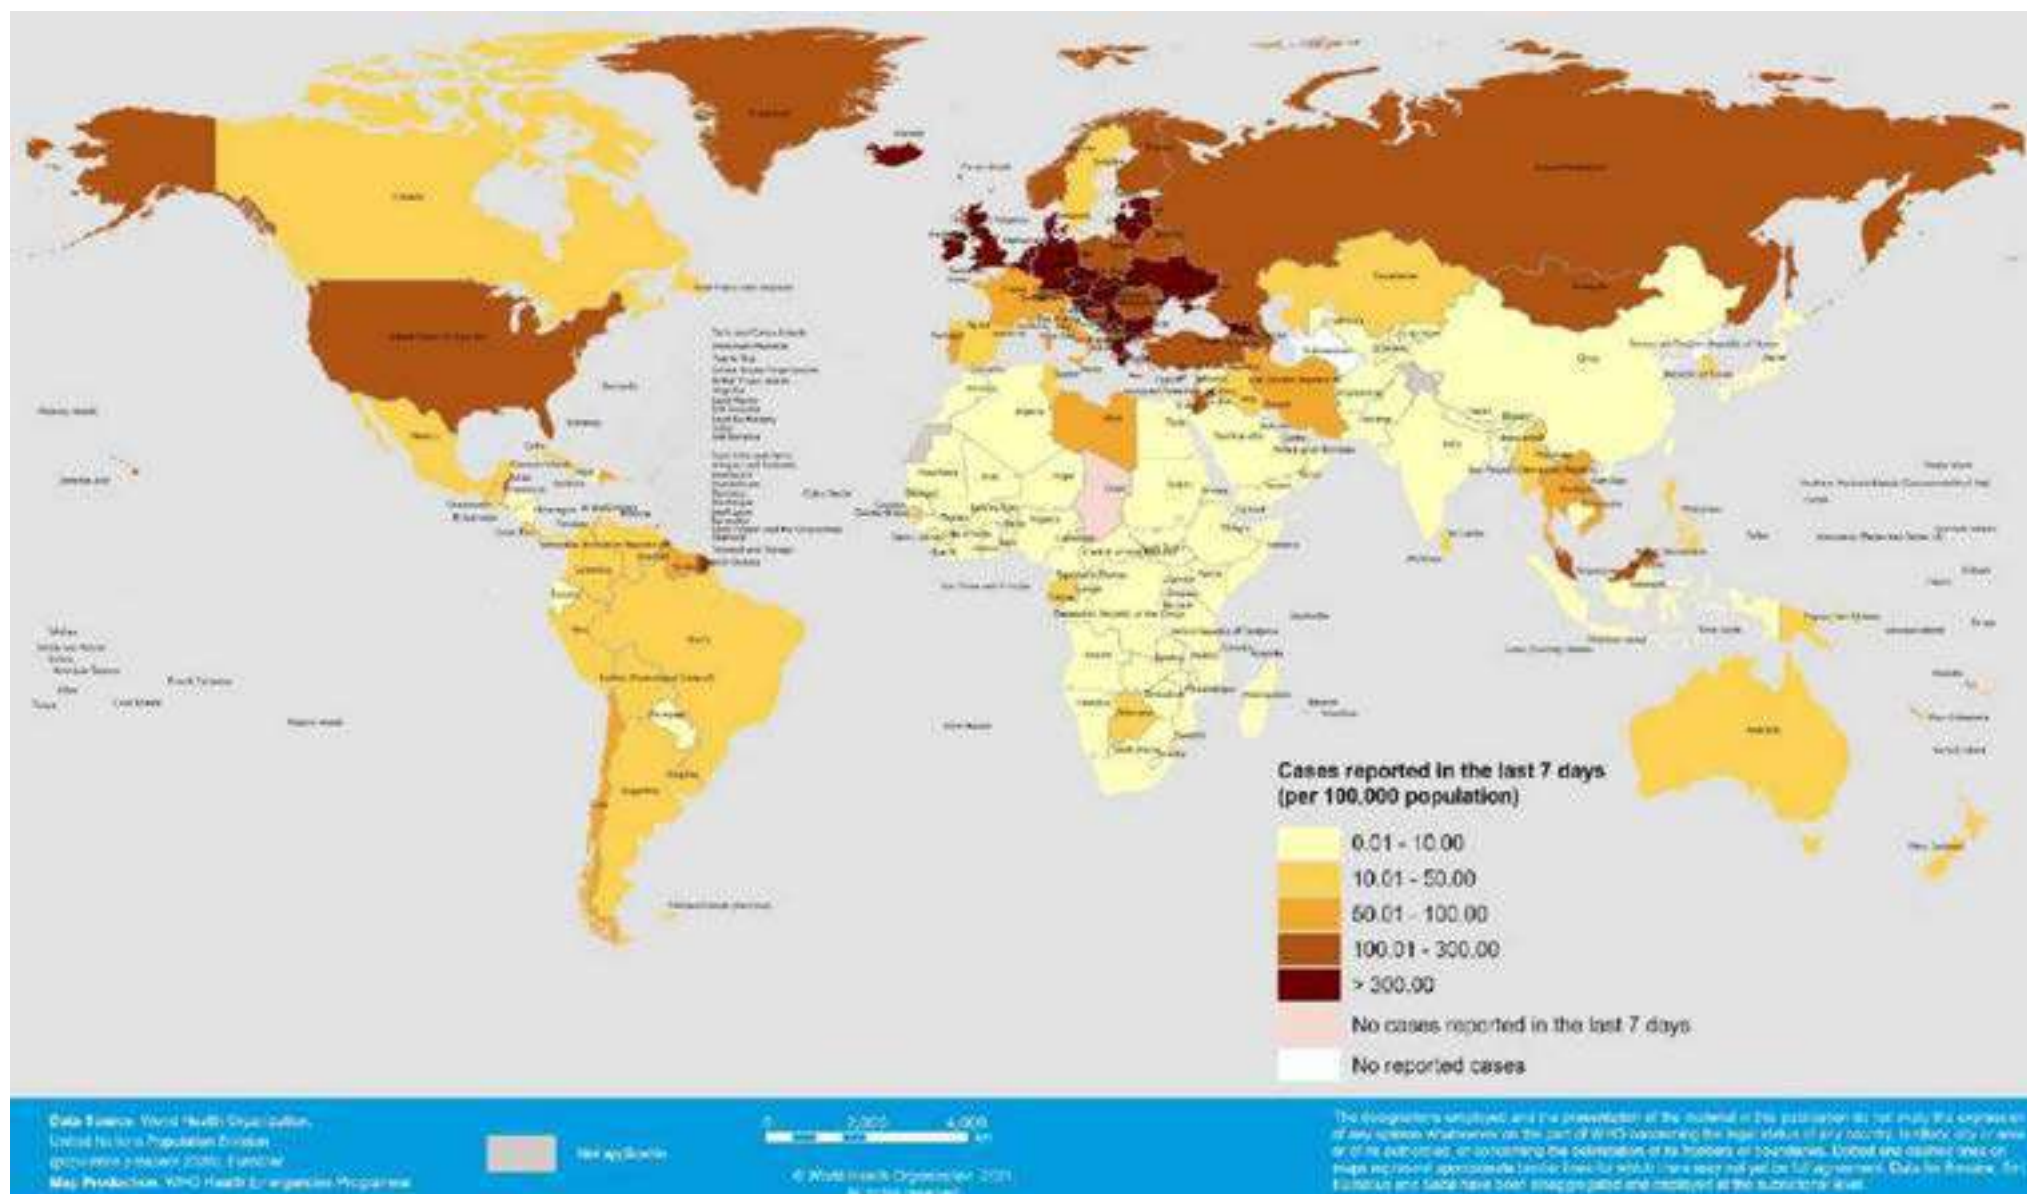

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Potential Variants of Concern (VOCs), Variants of Interest (VOIs) or Variants Under Monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

Geographic spread and prevalence of VOCs

The current global genetic epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, with the declining prevalence of other variants among sequences submitted to publicly available datasets or detections reported to WHO (Figure 4, Annex 2). Delta has outcompeted other variants, including other VOCs, in most countries. Of 799 645 sequences uploaded to [GISAID](#) with specimens collected in the last 60 daysⁱ, 797 174 (99.7%) were Delta, 791 (0.1%) Gamma, 313 (<0.1%) Alpha, 15 (<0.1%) Beta, and 0.1% comprised other circulating variants (including VOIs Mu and Lambda). Sub-regional and country-level variation continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual, and other variants (e.g., Gamma, Lambda, Mu) still contribute a large proportion of reported sequences. Moreover, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Phenotypic characteristics

Available evidence on the phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the last detailed update on 2 November, there are several new publications on the phenotypic characteristics of VOCs.

Results from a retrospective cohort study¹ of patients admitted to a referral hospital in Cape Town, South Africa, were published in a preprint on 4 November 2021. The study compares outcomes between two time periods: 26 March and 10 July 2020 (wave 1) and 15 November 2020 to 15 January 2021 (wave 2). A total of 1182 patients aged 18 years and over were included in the study: 571 during the first wave, and 611 during the second wave. Despite the reported higher numbers of cases and deaths during the second wave, there was no difference in the mortality risk [adjusted odds ratio (aOR) of 0.97, 95% confidence interval (CI) of 0.55-1.7, $p=0.9$]. Whole-genome sequencing performed on samples from the second wave, found that 97% (113/117) of those tested were identified as the Beta variant. It is possible that the increased use of corticosteroids (92.6% in the second wave as compared to 13.7% in the first), which was found to be associated with lower odds of mortality (aOR=0.4, 95%CI 0.28-0.84, $p=0.01$), and intensified anticoagulation (93.5% in the second as compared to 62.7% in the first) improved survival.

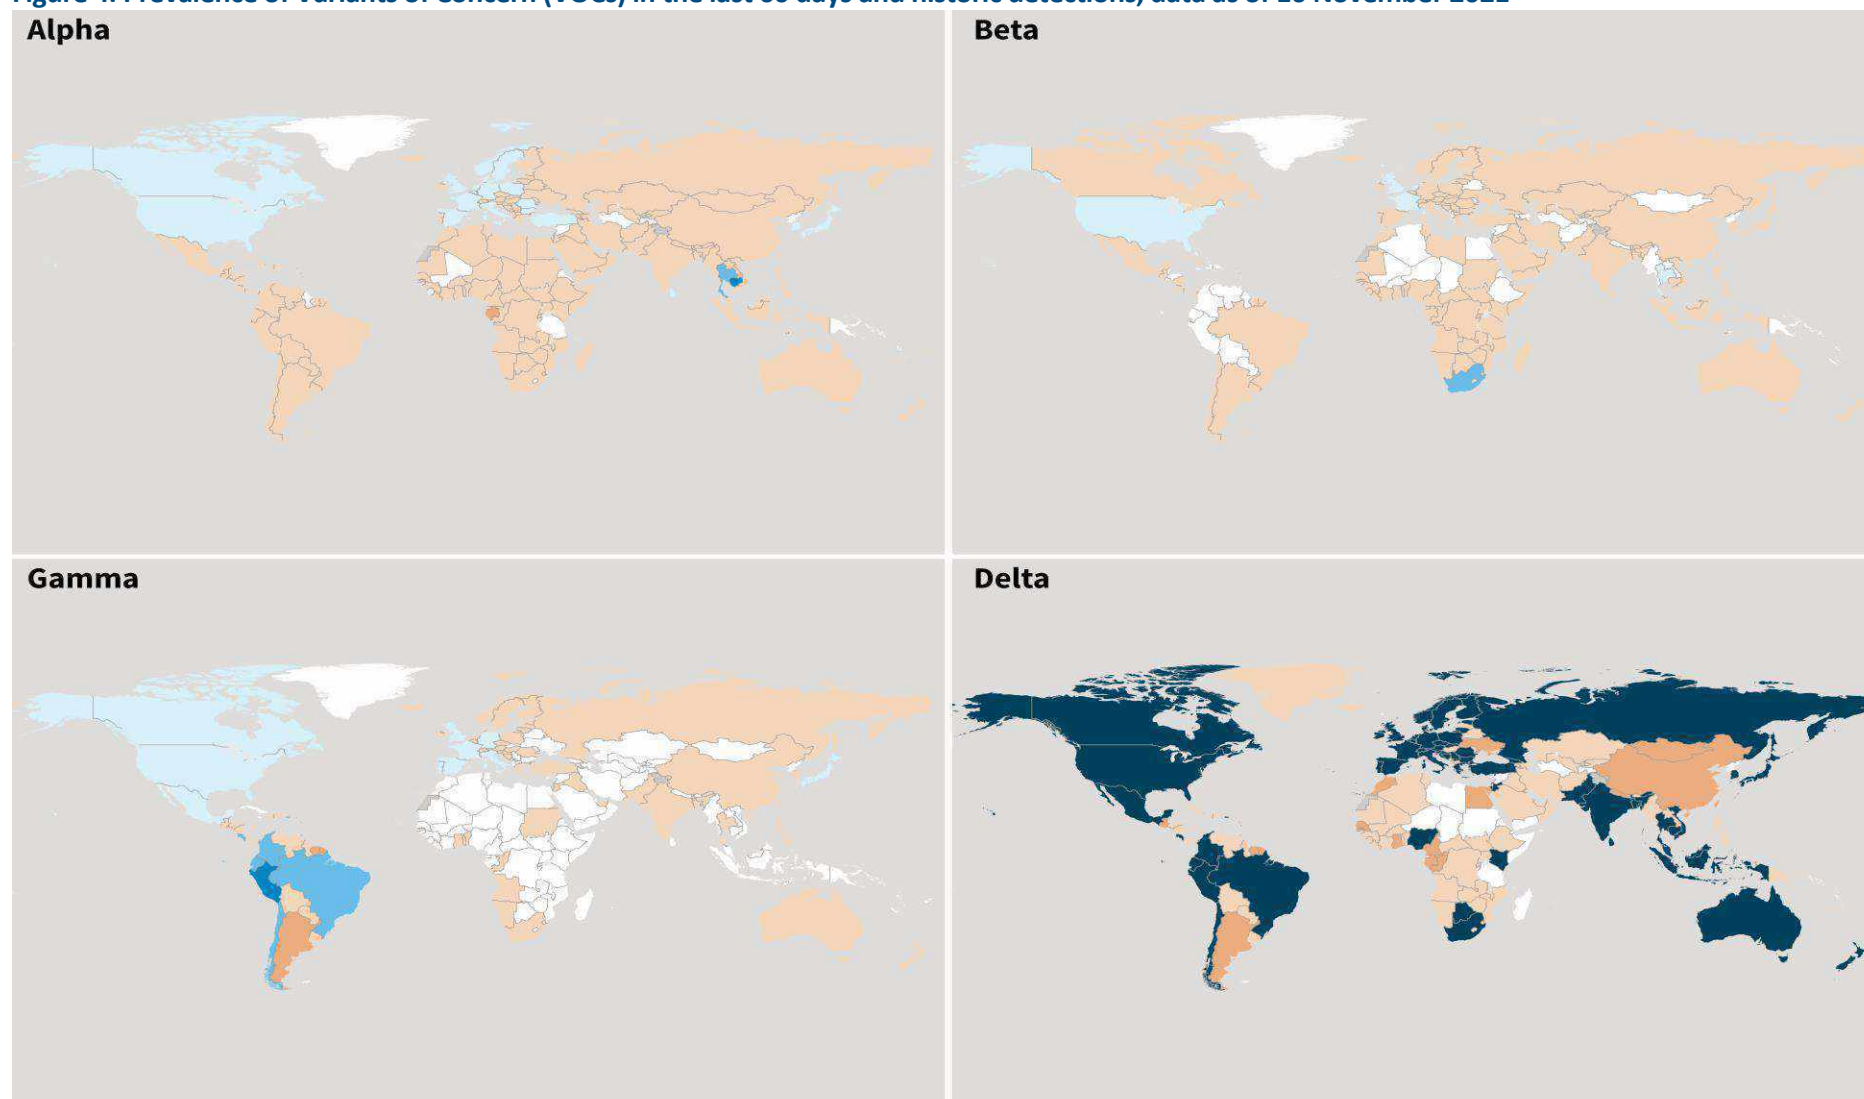

A pre-print study,² conducted in the United States of America during a period when Delta variant prevalence was above 95%, evaluated whether vaccine-induced immune responses reduce the amount of nasal viral RNA or the infectious virus titers as compared to the responses in infected, but unvaccinated persons. Authors compared RT-PCR cycle threshold (Ct) data from 699 test-positive anterior nasal swab specimens from fully vaccinated ($n=310$) or unvaccinated ($n=389$) COVID-19 cases. Fully vaccinated was defined as having received a second mRNA vaccine dose or single adenovirus vector vaccine dose ≥ 2 weeks prior to testing positive. Low Ct values (<25) were observed in

ⁱ Includes sequences submitted to [GISAID](#) with sample collected dates from 13 September to 12 November 2021 (last reported sample at the time of data extraction), excluding low coverage sequences.

212 of 310 fully vaccinated (68%) and 246 of 389 (63%) unvaccinated individuals, regardless of symptoms at the time of testing. Plaque assays were performed on an additional set of 48 samples with Ct <25, finding no difference in infectious virus titer between vaccinated and unvaccinated groups ($p=0.40$). Combined with other studies,^{3,4} these data indicate that vaccinated as well as unvaccinated individuals infected with the Delta variant may be able to transmit the virus, although other studies suggest this transmission by immunized individuals may be relatively inefficient, as vaccination accelerates viral clearance.⁵

Preliminary analysis reported in a technical briefing by the United Kingdom Health Security Agency using surveillance data from the United Kingdom⁶ between 1 August to 5 October 2021 suggests that estimated growth rates remain slightly higher for the Delta sub-lineage AY.4.2 than for other Delta lineages (parental Delta and Delta sub-lineages other than AY.4.2) and that the secondary attack rate for household contacts of cases with AY.4.2 may be slightly higher than for contacts of Delta cases (12.2% (95% CI: 11.8% - 12.7%) vs. 11.2% (95% CI: 11.1% - 11.3%). In non-household settings, the secondary attack rate was higher for AY.4.2 as compared to Delta cases, but this difference was not significant.⁷ Initial analyses did not show strong evidence of a difference in risk of hospitalization or death between AY.4.2 and Delta (parental and sub-lineages other than AY.4.2). It is important to note that these analyses did not adjust for crucial factors that can influence outcomes such as age and vaccination status and should be interpreted with caution.

Figure 4. Prevalence of Variants of Concern (VOCs) in the last 60 days and historic detections, data as of 16 November 2021

*Prevalence calculated as a proportion of VOC sequences among total sequences uploaded to GISAID with sample collection dates within the past 60 days prior to the latest date of collection, excluding low coverage sequences, limited to countries with ≥100 total sequences in the same period. Countries assigned by location of sample collection.

**Includes both official reports to WHO and unofficial reports of VOC detections.

The designations employed and the presentation of the material in this publication do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement.

Prevalence data based on sequences reported to [GISAID](#), excluding low coverage sequences. See also [Annex 2](#) for reported VOC detections by country/territory/area

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility ⁸	Increased transmissibility ^{9,10}	Increased transmissibility ^{10,11}	Increased transmissibility ^{6,10,12,13}
Disease severity	Possible increased risk of hospitalization ^{14,15} , possible increased risk of severe disease and death ^{16,17}	Possible increased risk of hospitalization ¹⁵ , possible increased in-hospital mortality ¹⁸	Possible increased risk of hospitalization ¹⁵ , possible increased risk of severe disease ¹⁹	Possible increased risk of hospitalization ^{20,21}
Risk of reinfection	Neutralizing activity retained ²² , risk of reinfection remains similar ²³	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²⁴	Moderate reduction in neutralizing activity reported ²⁵	Reduction in neutralizing activity reported ^{26–28}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ²⁹	No impact on RT-PCR or Ag RDTs observed ²⁸	None reported to date	No impact on RT-PCR or Ag RDTs observed ³⁰

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

Table 3 summarizes the impact of variants on product-specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to non-VOC settings. Since the [2 November update](#), five notable new studies have provided evidence of COVID-19 vaccine performance against variants of concern.

A peer-reviewed large retrospective cohort study from Scotland evaluated the effectiveness of AstraZeneca-Vaxzevria and Pfizer BioNTech-Comirnaty vaccines at preventing death among 98 066 persons who were aged 18 years and older and who tested positive for infection with the Delta variant.³¹ VE against death among those infected with Delta was 91% (95% CI: 86-94%) for AstraZeneca-Vaxzevria and 90% (83-94%) for Pfizer BioNTech-Comirnaty. The maximum possible follow-up time post-second dose for this study was approximately 25 weeks.

A second test-negative case-control study from the United States of America, peer-reviewed, found the Pfizer BioNTech-Comirnaty vaccine to be 90% (89-91%) effective at preventing hospitalization ≥ 14 days post-second dose among immunocompetent adults aged 18 years and older, and 79% (74-83%) effective at preventing hospitalization among immunocompromised adults (individuals with an impaired immune system).³² The maximum potential follow-up time post full vaccination was approximately 33 weeks for this study. The median interval from time of second dose to hospital admission was 89-90 days for both vaccines for both immunocompetent and immunocompromised adults.

A retrospective cohort study from Finland (not yet peer-reviewed) assessed the effectiveness of AstraZeneca-Vaxzevria, two doses of mRNA, and heterologous AstraZeneca-Vaxzevria/mRNA vaccination at preventing infection and hospitalization among healthcare workers with increasing time since vaccination.³³ VE of two doses of mRNA vaccine against SARS-CoV-2 infection declined from 85% (81-88%) 14-90 days after the second dose to 56% (46-65%) after 6 months. VE of AstraZeneca-Vaxzevria against infection declined from 88% (71-95%) 14-90 days after the second dose to 62% (-177-95%) 91-180 days post second dose. VE of heterologous AstraZeneca-Vaxzevria/mRNA vaccination declined from 80% (72-86%) 14-90 days post second dose to 63% (33-80%) 91-180 days post second dose (no estimates were available for 6+ months for these regimens). VE against hospitalization remained high (>95%) for mRNA vaccination and heterologous AstraZeneca/mRNA vaccination through 180 days post second dose; VE against

hospitalization for homologous AstraZeneca-Vaxzevria decreased from 100% ($-\infty$, 100) 14-90 days post second dose to 81% (9-96%) 91-180 days post second dose.

Finally, a peer-reviewed, large retrospective study from Israel assessed the effectiveness of the third dose of Pfizer BioNTech-Comirnaty vaccine compared to those who had received two doses of the same vaccine 5 or more months prior to the analysis.³⁴ A third dose of the Pfizer BioNTech-Comirnaty vaccine was 88% (87-90%), 91% (89-92%), 92% (82-97%), and 81% (59-97%) more effective at preventing infection, symptomatic disease, severe disease, and death, seven or more days after the booster dose.

VE refers to vaccine effectiveness and vaccine efficacy;

⁺As of submission of this update

*Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in the study. The number of studies is shown as subscripts: VE and neutralization studies informing this table can be found on the [VIEW-hub Resource Library](#). References indicated by superscripts next to VOC label are VE from randomized controlled trials (RCTs) informing this table.

African Region

The case incidence rates in the African Region have continued to decline since July, with a 33% decrease reported as compared to the previous week. However, 31% (15/49) of the countries in the region reported an increase of >10% in new cases as compared to the previous week. Over 500 new deaths were reported this week, similar to the previous week's figures. The highest numbers of new cases were reported from South Africa (1926 new cases; 3.2 new cases per 100 000 population; similar to the previous week), Ethiopia (1584 new cases; 1.4 new cases per 100 000; a 25% decrease), and Cameroon (1371 new cases; 5.2 new cases per 100 000; a 26% decrease).

The highest numbers of new deaths were reported from South Africa (157 new deaths; <1 new death per 100 000 population; similar to the previous week's figures), Ethiopia (82 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Nigeria (55 new deaths; <1 new death per 100 000; a 450% increase).

Updates from the [African Region](#)

Region of the Americas

The trend in cases in the Region of the Americas increased slightly with over 758 000 new cases reported, an 8% increase as compared to the previous week. Over 12 000 new deaths were reported, a number similar to that of the previous week. Thirty-two percent (19/59) of countries reported an increase of >10% in the number of new cases in the past week. The highest numbers of new cases were reported from the United States of America (550 684 new cases; 166.4 new cases per 100 000; an 8% increase), Brazil (76 738 new cases; 36.1 new cases per 100 000; an 11% increase), and Mexico (19 831 new cases; 15.4 new cases per 100 000; similar to the previous week's figures).

The highest numbers of new deaths were reported from the United States of America (7993 new deaths; 2.4 new deaths per 100 000; a 15% decrease), Mexico (1458 new deaths; 1.1 new deaths per 100 000; similar to the previous week), and Brazil (1431 new deaths; <1 new death per 100 000; a 10% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

Case and death incidence rates in the Eastern Mediterranean Region have continued to decline since mid-July, with over 101 000 new cases and over 1900 new deaths reported, a 9% and 14% decrease, respectively as compared to the previous week. Out of the 22 countries in the Region, five reported an increase of over 10% in new cases, in the past week. The highest numbers of new cases were reported from the Islamic Republic of Iran that contributed to half of the cases in the Region (51 315 new cases; 61.1 new cases per 100 000; a 20% decrease), followed by Jordan (15 964 new cases; 156.5 new cases per 100 000; a 24% increase), and Iraq (6449 new cases; 16.0 new cases per 100 000; a 17% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (869 new deaths; 1.0 new deaths per 100 000; a 17% decrease), Egypt (424 new deaths; <1 new death per 100 000; similar to the previous week's figures), and Iraq (164 new deaths; <1 new death per 100 000; a 9% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region has continued to show an increasing trend in both cases and deaths, with over 2.1 million new cases and over 28 000 new deaths reported, increases of 8% and 5%, respectively as compared to the previous week. Nearly half (46%) of the countries which were widely distributed across the Region reported increases of over 10% in new cases in the past week, including Germany which reported the second-highest number of new cases in the past week and a 50% increase in cases as compared to the week before (254 436 new cases; 305.9 new cases per 100 000; a 50% increase). The other countries reporting the highest numbers of new cases were the Russian Federation (275 579 new cases; 188.8 new cases per 100 000; similar to the previous week's figures), and the United Kingdom (252 905 new cases; 372.5 new cases per 100 000; similar to the previous week's figures).

An increase of over 10% in deaths in the past week was seen in 38% of the countries with the greatest change seen in Norway (a 67% increase), Slovakia (a 58% increase), and Croatia (a 55% increase). The countries reporting the highest numbers of new deaths included the Russian Federation (8572 new deaths; 5.9 new deaths per 100 000; similar to the previous week's figures) and Ukraine (4621 new deaths; 10.6 new deaths per 100 000; a 6% increase).

Updates from the [European Region](#)

South-East Asia Region

Following a declining trend since July, the incidence of cases and deaths in the South-East Asia Region has begun to plateau with over 152 000 new cases and over 3500 new deaths, similar numbers as compared to the previous week. Three of the ten countries in the region, reported increases of over 10% in new cases in the past week, while the highest numbers of new cases were reported from India (81 771 new cases; 5.9 new cases per 100 000; similar to the previous week's figures), Thailand (50 411 new cases; 72.2 new cases per 100 000; a 10% decrease), and Myanmar (6446 new cases; 11.8 new cases per 100 000; similar to the previous week's figures).

The highest numbers of new deaths were reported from India (2739 new deaths; <1 new death per 100 000; similar to the previous week's figures), Thailand (372 new deaths; <1 new death per 100 000; a 19% decrease), and Sri Lanka (139 new deaths; <1 new death per 100 000; a 23% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

During the past several weeks, the incidences of cases and deaths have been relatively stable with just under 174 000 new cases and over 2400 new deaths reported over this past week, a 6% increase and a 5% decrease, respectively as compared to the previous week. However, five of the 27 countries in the Region (19%) reported an increase this week as compared with the previous week, with the greatest changes reported in Fiji (a 42% increase), Viet Nam (a 26% increase), and New Zealand (a 20% increase). Viet Nam also reported the highest number of new cases (57 308; 58.9 new cases per 100 000).

The highest numbers of new deaths were reported from the Philippines (1033 new deaths; <1 new death per 100 000; an 14% decrease), Viet Nam (548 new deaths; <1 new death per 100 000; a 25% increase), and Malaysia (375 new deaths; 1.2 new deaths per 100 000; similar to the previous week's figures).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 15 November, highlights include the following:

- Delivering 6.6 tonnes of emergency medical kits to Sierra Leone following a fire disaster
- COVID-19 Intra-Action Review (IAR) in North Macedonia
- Launching nationwide vaccination campaign to scale up immunity against COVID-19 in Iraq
- Saving young lives through essential health services in Kenya
- Using social and behavioural data to fight COVID-19
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

Annexes

Annex 1. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection, as is the case for AstraZeneca-Vaxzevria.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine the level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from the same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as a comparator). In some instances, a study may be included for severe disease or infection outcomes even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.

Annex 2. List of countries/territories/areas reporting variants of concern as of 16 November 2021

Country/Territory/Area	Alpha	Beta	Gamma	Delta

*Newly reported in this update. indicates that information for this variant was received by WHO from official sources. indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 3: Data, table, and figure notes](#)

Annex 3. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at the global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises that remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, the number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 65, published 9 November 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 7 November 2021

During the week 1 to 7 November 2021, a slight upward trend (1% increase) in new weekly cases was observed, with just over 3.1 million new cases reported (Figure 1). The WHO European Region reported a 7% increase in new weekly cases as compared to the previous week, while other regions reported declines or stable trends (Table 1). Similarly, the European Region reported a 10% increase in new deaths, while other regions reported declining trends. Globally, over 48 000 new deaths were reported, a 4% decrease from the previous week.

As of 7 November, over 249 million confirmed cases and over 5 million deaths have been reported.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 7 November 2021**

**See [Annex 2: Data, table, and figure notes](#)

The regions reporting the highest weekly case incidence rates per 100 000 population were the European Region (208.9 new cases per 100 000 population) and the Region of the Americas (68.6 new cases per 100 000 population).

population); the same two regions reported the highest weekly incidence in deaths, of 2.9 and 1.3 per 100 000 population, respectively.

The highest numbers of new cases were reported from the United States of America (510 968 new cases; 3% decrease), the Russian Federation (281 305 new cases; 3% increase), the United Kingdom (252 104 new cases; 12% decrease), Turkey (197 335 new cases; 8% increase), and Germany (169 483 new cases; 29% increase).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 7 November 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	1 949 419 (63%)	7%	78 757 071 (32%)	26 726 (55%)	10%	1 452 069 (29%)
Americas	701 791 (23%)	-5%	94 330 064 (38%)	13 106 (27%)	-14%	2 307 543 (46%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Potential Variants of Concern (VOCs), Variants of Interest (VOIs) or Variants Under Monitoring (VUMs) are regularly assessed based on the risk posed to global public health. As evidence becomes available, classifications of variants will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and VUMs, are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

On 9 November 2021, a list of formerly monitored variants was included on the [WHO Tracking SARS-CoV-2 variants website](#). This comprises former VOCs/VOIs/VUMs, including their lineages, that have been found to no longer be circulating at levels of global public health significance; had been circulating for a long time without major impacts on the overall epidemiological situation; or, scientific evidence demonstrated that the variant is not associated with concerning properties. In addition to three previously reclassified variants, 10 VUMs were recently reclassified to this category based on diminishing numbers of detections and epidemiological risks. These variant classifications will be revisited if new evidence of epidemiological or phenotypic impacts becomes available.

Geographic spread and prevalence of VOCs

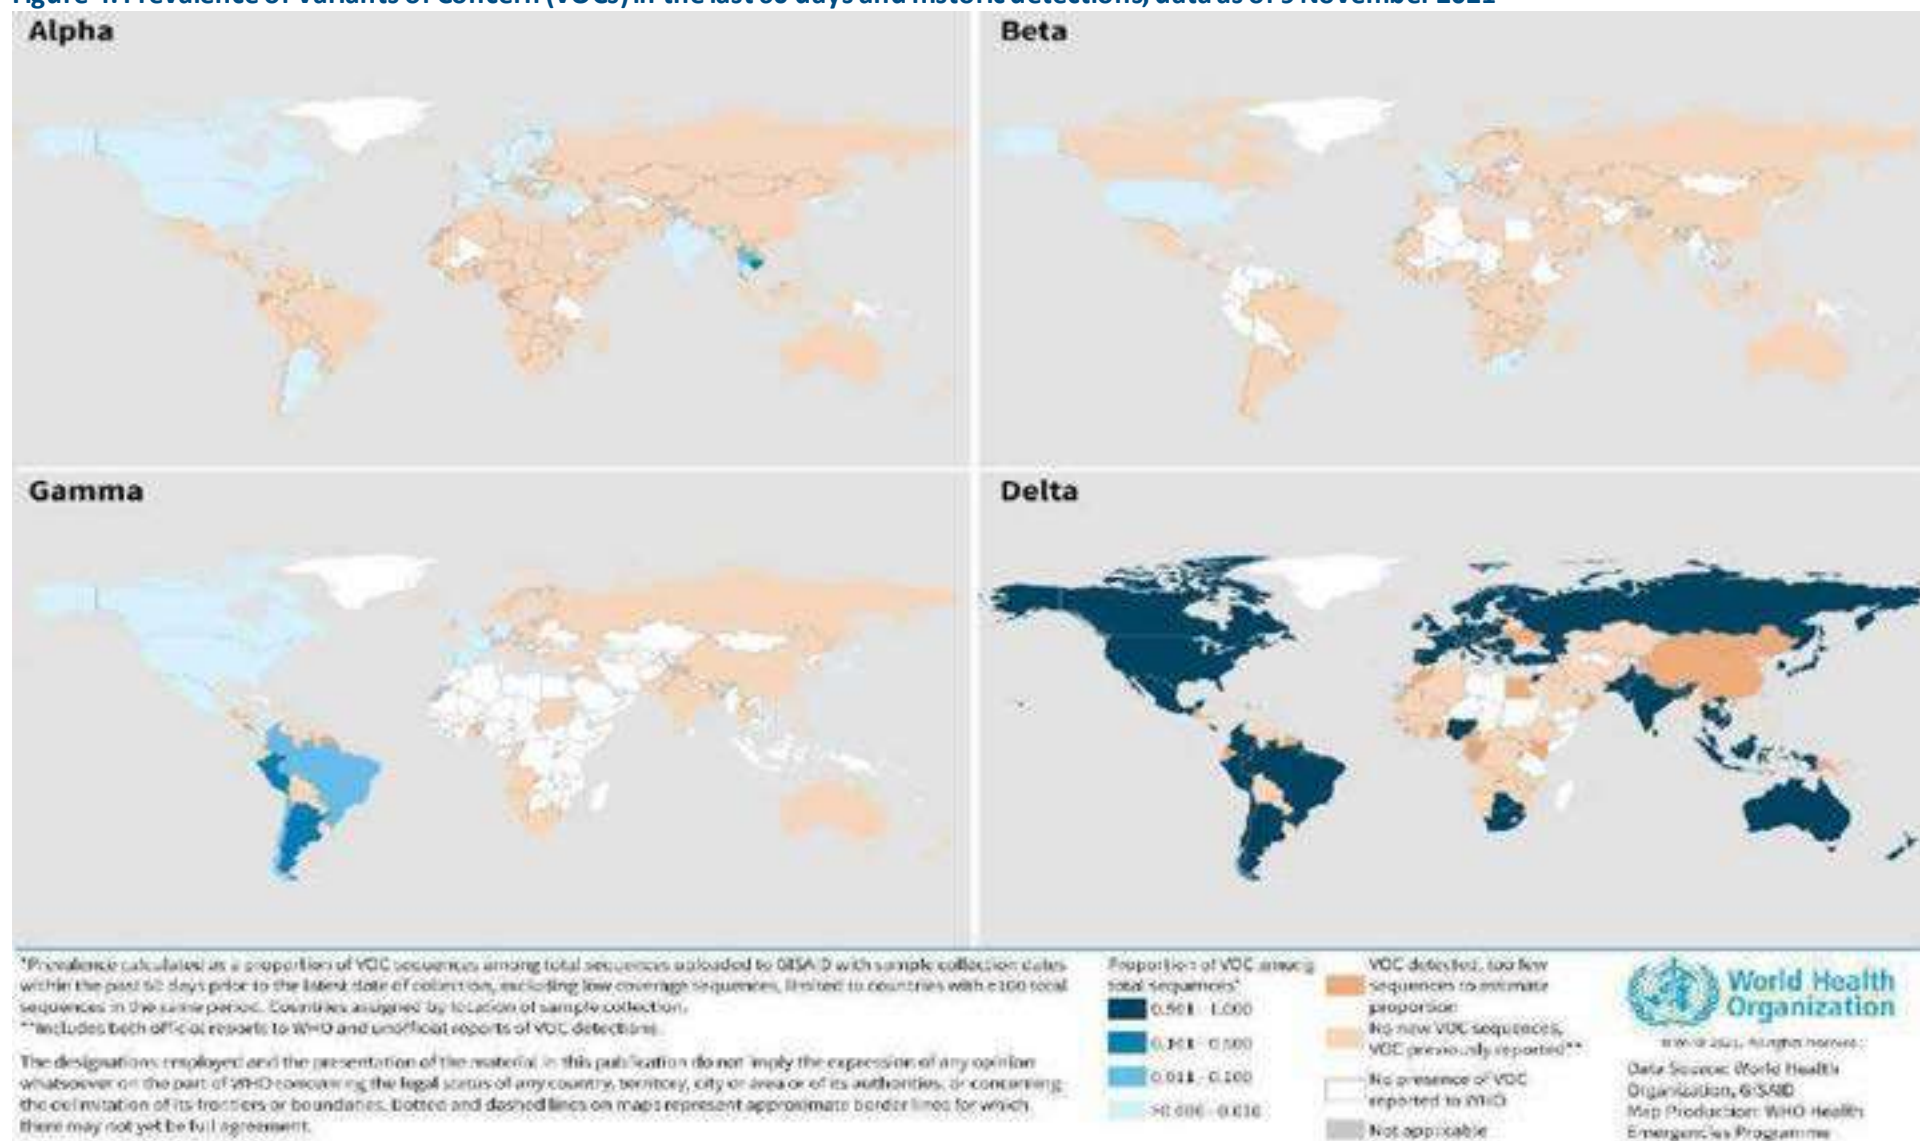

The current global genetic epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, with declining prevalence of other variants among sequences submitted to publicly available datasets or detections reported to WHO (Figure 4, Annex 1). Delta has outcompeted other variants, including other VOCs, in most countries. Of 814 165 sequences uploaded to [GISAID](#) with specimens collected in the last 60 days¹, 810 946 (99.6%) were Delta, 1163 (0.1%) Gamma, 400 (<0.1%) Alpha, 23 (<0.1%) Beta, and 0.2% comprised other circulating variants (including VOIs Mu and Lambda). Sub-regional and country-level variation continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual, and other variants (e.g., Gamma, Lambda, Mu) still contribute a large proportion of reported sequences. Moreover, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, as well as delays in reporting.

Prevalence data based on sequences reported to [GISAID](https://gisaid.org/), excluding low coverage sequences. See also [Annex 1](#) for reported VOC detections by country/territory/area

WHO regional overviews Epidemiological week 1-7 November 2021

African Region

After a decreasing trend since July 2021, case incidence rates in the African Region have begun to plateau, with over 20 000 new cases reported this week. Over 500 new deaths were reported, a 27% decrease as compared to the previous week. However, substantial increases (>15%) in new cases were reported in a third of the countries in the region (15/49; 31%). The highest numbers of new cases were reported from Botswana (6341 new cases; 269.6 new cases per 100 000 population; a 279% increase; largely due to batch reporting), Ethiopia (2102 new cases; 1.8 new cases per 100 000; a 37% decrease), and South Africa (1865 new cases; 3.1 new cases per 100 000; a 27% decrease).

The highest numbers of new deaths were reported from South Africa (156 new deaths; <1 new death per 100 000 population; a 37% decrease), Ethiopia (80 new deaths; <1 new death per 100 000; a 32% decrease), and Cameroon (45 new deaths; <1 new death per 100 000; a 48% decrease).

Updates from the [African Region](#)

Region of the Americas

The overall declining trend continued this week in the Region of the Americas, with over 701 000 new cases and over 13 000 new deaths reported, decreases of 5% and 14% respectively as compared to the previous week. Despite this, 9% (5/59) of countries reported an increase in the number of new cases in the past week. The highest numbers of new cases were reported from the United States of America (510 968 new cases; 154.4 new cases per 100 000; a 3% decrease), Brazil (69 057 new cases; 32.5 new cases per 100 000; a 15% decrease), and Mexico (19 543 new cases; 15.2 new cases per 100 000; a 4% increase).

The highest numbers of new deaths were reported from the United States of America (8101 new deaths; 2.4 new deaths per 100 000; a 15% decrease), Brazil (1598 new deaths; <1 new death per 100 000; a 31% decrease), and Mexico (1463 new deaths; 1.1 new deaths per 100 000; a 5% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

After a decreasing trend since mid-August 2021, case and death incidence rates in the Eastern Mediterranean Region have begun to plateau, with over 112 000 new cases and over 2200 new deaths reported. Out of the 22 countries in the Region, four reported an increase of over 10% in new cases, in the past week. The highest numbers of new cases were reported from the Islamic Republic of Iran that contributed to half of cases in the Region (64 049 new cases; 76.3 new cases per 100 000; similar to previous week), followed by Jordan (12 889 new cases; 126.3 new cases per 100 000; a 17% increase), and Iraq (7737 new cases; 19.2 new cases per 100 000; a 16% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1047 new deaths; 1.2 new deaths per 100 000; similar to previous week), Egypt (419 new deaths; <1 new death per 100 000; a 20% increase), and Iraq (181 new deaths; <1 new death per 100 000; a 10% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region has continued to show an increasing trend in both cases and deaths, with over 1.9 million new cases and over 26 000 new deaths reported, increases of a 7% and a 10% increase respectively as compared to the previous week. Out of the 61 countries in the Region, 26 (42%) reported increases of 10% or more in cases in the past week. The highest numbers of new cases were reported from Russian Federation (281 305 new cases; 192.8 new cases per 100 000; a 3% increase), The United Kingdom (252 104 new cases; 371.4 new cases per 100 000; a 12% decrease), and Turkey (197 335 new cases; 234.0 new cases per 100 000; an 8% increase).

The highest numbers of new deaths were reported from the Russian Federation (8276 new deaths; 5.7 new deaths per 100 000; similar to the previous week's figures), Ukraine (4355 new deaths; 10.0 new deaths per 100 000; a 13% increase), and Romania (3158 new deaths; 16.3 new deaths per 100 000; similar to the previous week's figures).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 157 000 new cases and over 3500 new deaths, a 13% and a 29% decrease respectively as compared to the previous week. This declining trend has been observed in the Region for over three months, notwithstanding a spike in deaths observed during the week 25-31 October which was largely due to a backlog in the reporting of deaths from an area in India. The highest numbers of new cases were reported from India (82 236 new cases; 6.0 new cases per 100 000; a 16% decrease), Thailand (55 975 new cases; 80.2 new cases per 100 000; a 9% decrease), and Myanmar (6743 new cases; 12.4 new cases per 100 000; a 16% increase).

The highest numbers of new deaths were reported from India (2605 new deaths; <1 new death per 100 000; a 33% decrease), Thailand (459 new deaths; <1 new death per 100 000; a 2% increase), and Indonesia (140 new deaths; <1 new death per 100 000; a 30% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Decreasing trends observed in Western Pacific Region continued this week, with over 162 000 new cases and over 2500 new deaths reported, decreases of 9% and 13% respectively as compared to the previous week. However, seven countries in the Region (25%) reported an increase this week as compared with the previous week. The highest numbers of new cases were reported from Viet Nam (45 435 new cases; 46.7 new cases per 100 000; a 48% increase), Malaysia (35 303 new cases; 109.1 new cases per 100 000; a 13% decrease), and Singapore (20 569 new cases; 351.6 new cases per 100 000; a 21% decrease).

The highest numbers of new deaths were reported from the Philippines (1195 new deaths; 1.1 new deaths per 100 000; an 18% decrease), Viet Nam (440 new deaths; <1 new death per 100 000; a 7% increase), and Malaysia (380 new deaths; 1.2 new deaths per 100 000; a 27% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 8 November, highlights include the following:

- WHO/Europe increases support to Romania during a critical phase of its COVID-19 response
- Belize receives twenty patient monitors as part of the India-UN Development Partnership Fund
- Partnering to support the COVID-19 response and resilience of Sri Lanka's primary health care system
- Returning migrant workers receive medical care and support in Lao People's Democratic Republic
- Emergency Medical Team (EMT) support to Mauritania
- WHO, faith partners and national governments collaborate for COVID-19 responses
- An offline intervention from WHO's Civil Society Organization (CSO) Initiative in the Philippines
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

**Newly reported in this update. indicates that information for this variant was received by WHO from official sources. indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available. **Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern. See also [Annex 3: Data, table, and figure notes](#).*

Annex 2. Data, table, and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the countries of interest, time period, and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories, and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory, or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories, and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 64, published 2 November 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)

Global overview

Data as of 31 October 2021

During the week 25 to 31 October 2021, a slight upward trend (3% increase) in new weekly cases was observed, with just over 3 million new cases reported (Figure 1). Apart from the WHO European Region, which reported a 6% increase in new weekly cases as compared to the previous week, other regions reported declines or stable trends (Table 1). The largest decreases were reported from the Eastern Mediterranean Region (12%), followed by the South-East Asia and African Regions (both 9%).

New weekly deaths increased by 8% as compared with the previous week, with over 50 000 new fatalities. The observed rise in new weekly deaths has been mainly driven by the South-East Asia Region, which reported the largest increase (50%), followed by the European Region (12%) and the Western Pacific Region (10%).

As of 31 October, over 246 million confirmed cases and nearly 5 million deaths have been reported.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 31 October 2021**

**See [Annex 3: Data, table and figure notes](#)

The regions reporting the highest weekly case incidence rates per 100 000 population were the European Region (192.3 new cases per 100 000 population) and the Region of the Americas (71.8 new cases per 100 000 population); the same two regions reported the highest weekly incidence in deaths, of 2.6 and 1.5 per 100 000 population, respectively.

The highest numbers of new cases were reported from the United States of America (528 455 new cases; 7% increase), the United Kingdom (285 028 new cases; 14% decrease), the Russian Federation (272 147 new cases; 9% increase), Turkey (182 027 new cases; 8% decrease), and Ukraine (152 897 new cases; 14% increase).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 31 October 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	1 794 518 (59%)	6%	76 784 507 (31%)	24 243 (48%)	12%	1 425 509 (29%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As evidence becomes available, classification for VOIs or VOCs will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification, and the current lists of VOCs, VOIs and other Variants Under Monitoring, are available on the [WHO Tracking SARS-Cov-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

Geographic spread and prevalence of VOCs

The current global genetic epidemiology of SARS-CoV-2 is characterized by a predominance of the Delta variant, with declining prevalence of other variants among sequences submitted to publicly available datasets or detections reported to WHO (Figure 4, Annex 2). Delta has outcompeted other variants, including other VOCs, in most countries. Of 842 510 sequences uploaded to GISAID with specimens collected in the last 60 days^a, 838 398 (99.5%) were Delta, 1545 (0.2%) Gamma, 584 (0.1%) Alpha, 43 (<0.1%) Beta, and 0.2% comprised other circulating variants (including VOIs Mu and Lambda). Sub-regional and country-level variation continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual, and other variants (e.g., Gamma, Lambda, Mu) still contribute a large proportion of reported sequences. Moreover, global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities, sampling strategies between countries and delays in reporting.

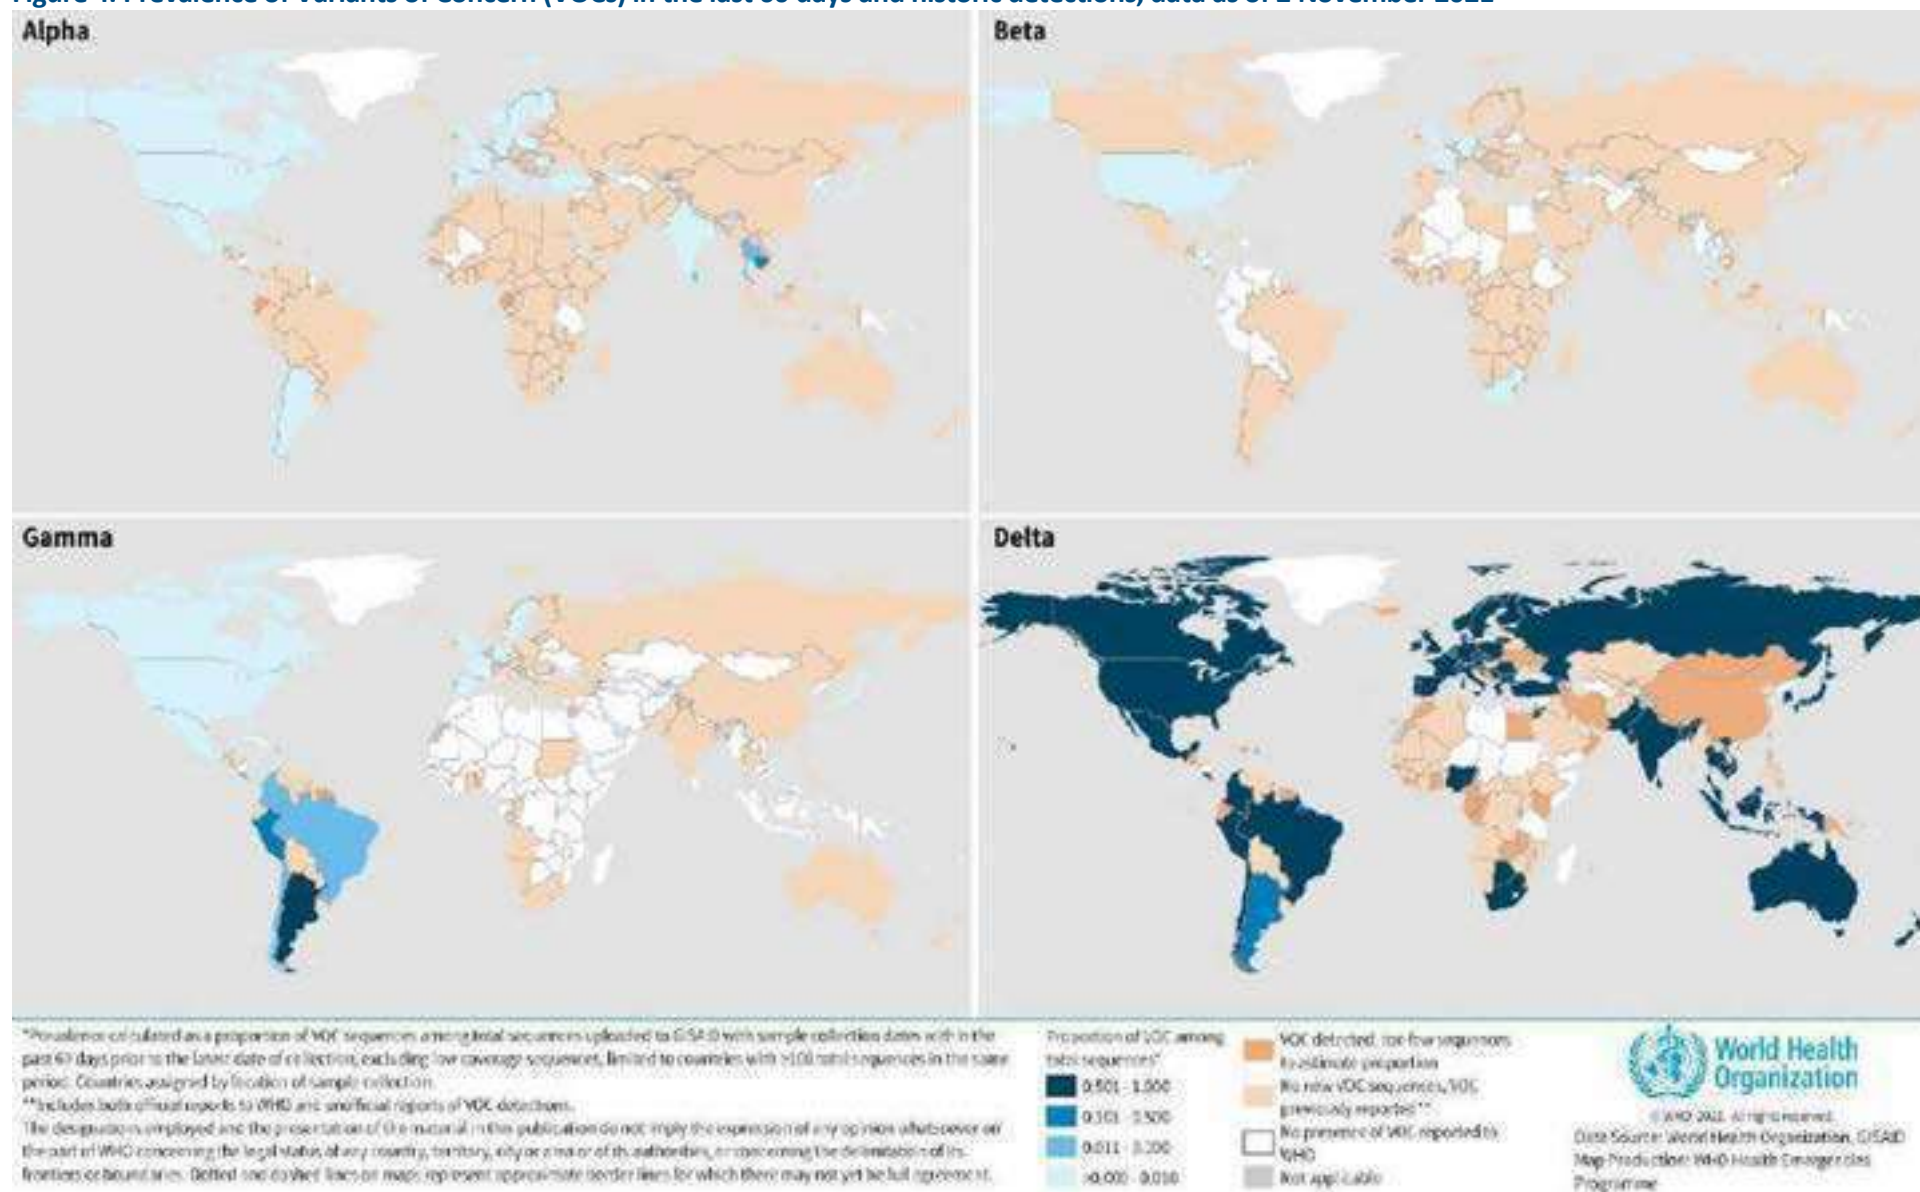

Phenotypic characteristics

Available evidence on the phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Update. Since the last detailed update on 19 October, there are several new publications on the phenotypic characteristics of VOCs.

A retrospective cohort study (peer-reviewed publication) conducted in Canada assessed the virulence of VOCs compared with non-VOC SARS-CoV-2 variants, as measured by risk of hospitalization, intensive care unit (ICU) admission and death.¹ The study population included 212 326 cases tested between 7 February 2021 and 25 June 2021. Compared with non-VOC variants, the pooled adjusted odds ratio associated with Alpha, Beta and Gamma variants was 1.52 (95% CI 1.42-1.63) for hospitalization, 1.89 (1.67-2.17) for ICU admission and 1.51 (1.30-1.78) for death. Increased risk with the Delta variant was more pronounced at 2.08 (1.78-2.40) for hospitalization, 3.35 (2.60-4.31) for ICU admission and 2.33 (1.54-3.31) for death, compared with non-VOC variants. In an additional analysis that excluded non-VOC cases, there was a significantly increased risk with Delta as compared with the pooled risk of Alpha, Beta and Gamma for hospitalization (adjusted OR 1.45, 95% CI 1.27–1.64), ICU admission (aOR 2.01, 1.60–2.47) and death (aOR 1.69, 1.16–2.35). Authors underlined that the study population infected with VOCs was, on average, younger and less likely to have comorbid conditions than non-VOC cases, but nonetheless had higher risks of hospitalization, ICU admission and deaths.

^a Includes sequences submitted to GISAID with sample collected dates from 30 August to 29 October 2021 (last reported sample at the time of data extraction), excluding low coverage sequences.

Figure 4. Prevalence of Variants of Concern (VOCs) in the last 60 days and historic detections, data as of 2 November 2021

Prevalence data based on sequences reported to [GISAID](#), excluding low coverage sequences. See also [Annex 2](#) for reported VOC detections by country/territory/area.

A peer-reviewed matched case-control study conducted in the United Kingdom estimated the odds of household transmission (≥ 2 cases within 14 days) for Delta variant index cases as compared with Alpha cases.² The study provides supporting evidence of increased transmissibility of the Delta variant, suggesting that it is more strongly associated with onward transmission within household settings as compared to the Alpha variant. During the study, cases were identified using national surveillance data between March and June 2021, matching controls based on geographical location of residence, time period of testing and property type. In total, 5976 index cases from clusters in households were sequenced and matched to 11 952 sporadic index cases (single case within a household). Of these, 43% (n=2586) of cases in household clusters were confirmed Delta variant cases as compared to 40% (n=4824) of sporadic cases. A 70% increase in the odds (aOR 1.70, 95% CI 1.48-1.95, $p < 0.001$) of household transmission was observed for infection with the Delta variant as compared to the Alpha variant, after adjusting for the index cases' vaccination status, sex, ethnicity, index of multiple deprivation, age group and number of household contacts.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility ³	Increased transmissibility ^{4,5}	Increased transmissibility ^{5,6}	Increased transmissibility ^{5,7,8}
Disease severity	Possible increased risk of hospitalization ^{9,10} , possible increased risk of severe disease and death ^{11,12}	Possible increased risk of hospitalization ¹⁰ , possible increased in-hospital mortality ¹³	Possible increased risk of hospitalization ¹⁰ , possible increased risk of severe disease ¹⁴	Possible increased risk of hospitalization ^{15,16}
Risk of reinfection	Neutralizing activity retained ¹⁷ , risk of reinfection remains similar ¹⁸	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ¹⁹	Moderate reduction in neutralizing activity reported ²⁰	Reduction in neutralizing activity reported ²¹⁻²³
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ²⁴	No impact on RT-PCR or Ag RDTs observed ²³	None reported to date	No impact on RT-PCR or Ag RDTs observed ²⁵

*Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision. Ag RDT = antigen-based rapid diagnostic test.

Table 3 summarises the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to non-VOC settings. Since the [19 October update](#), five notable new studies have provided evidence of COVID-19 vaccine performance against VOCs and VOIs.

A large test-negative case-control study from Canada (not yet peer-reviewed) evaluated the effectiveness of three vaccines, including heterologous regimens, at preventing infections and hospitalizations due to Alpha, Gamma, and Delta variants for residents 18 years and older in British Columbia and Quebec provinces.²⁶ For brevity, results are presented here for British Columbia, as the results from Quebec were similar, except where indicated. VE results are presented for fully vaccinated individuals. VE against infection due to Alpha was 74% (95% CI: 29-90%) for AstraZeneca-Vaxzevria, 95% (85-98%) for Moderna-mRNA-1273, 96% (93-98%) for Pfizer BioNTech-Comirnaty, 74% (29-90%) for heterologous regimes of AstraZeneca-Vaxzevria followed by an mRNA vaccine, and 96% (93-98%) for heterologous mRNA vaccinations. VE against infection due to Gamma was >90% for all vaccines, including both heterologous regimens. Pfizer BioNTech-Comirnaty effectiveness against hospitalization due to Alpha and Gamma was 96% (83-99%) and 95% (83-99%), respectively. VE against infection due to Delta was greater than 90% for all vaccines/regimens, except for homologous AstraZeneca vaccination (VE 70%, 66-73%). All vaccines/regimens showed >90% VE against hospitalization due to Delta after ≥ 14 days following a second dose.

To assess waning effectiveness, the same study measured VE against Delta infections and hospitalizations at different time intervals following complete vaccination. VE of both homologous mRNA vaccine regimens against infection peaked above 90% at 2-3 weeks after a second dose, and declined to 80% at 6 months. VE of heterologous mRNA vaccination against infection also peaked 97% (92-99%) at 2-3 weeks, and declined to 88% (82-91%) at 4 months. Similarly, VE of two AstraZeneca-Vaxzevria doses against infection peaked at 77% at 2-3 weeks, declining to 65% at 4+ months. All vaccines/regimens maintained high VE against hospitalization: Pfizer BioNTech-Comirnaty was 98% (91-99%) effective at 7+ months. Moderna-mRNA-1273 was 95% effective up to 4 months, declining slightly to 84% (63-93%) at 5 months; though data at this final time point was less robust and results from Quebec show a corresponding VE of >90% at 4+ months. AstraZeneca-Vaxzevria was 92% (81-97%) effective at 4+ months. Finally, VE for heterologous mRNA vaccination maintained a high VE of 98% (85-100%) at 4 months. The findings above underscore the continued effectiveness of the vaccines against severe disease associated with the Delta variant.

Two recent peer-reviewed studies from the United States of America assessed VE during periods of high Delta circulation. The first, a test-negative case-control study found that two doses of Pfizer BioNTech-Comirnaty was 93% (83%–97%) effective against hospitalization among children aged <18 years, with a maximum follow-up time of 14 weeks.²⁷ The second, a retrospective cohort study conducted during an outbreak of Delta among incarcerated men, found VE of two doses of Moderna-mRNA-1273 against infection and symptomatic disease to be 56.6% (42.0-67.5%) and 84.2% (56.4-94.3%), respectively, with a maximum follow-up time of ~27 weeks.²⁸ Of note, force of infection in closed facilities outbreaks is likely greater, and may lead to lower VE estimates than in the general population.

A fourth study (not yet peer-reviewed) used a test-negative case-control design to assess the effectiveness of Janssen-Ad26.COVS.2 among adults in Brazil during a period when Gamma was predominant.²⁹ Janssen-Ad26.COVS.2 was found to be 50.9% (35.5-63.0%), 72.9% (35.1-91.1%), and 90.5% (31.5-99.6%) effective in preventing symptomatic COVID-19, hospitalization, and death, respectively, 28 days or more following immunisation, with a maximum follow-up time of ~10 weeks.

Finally, a national population-based cohort study from Colombia (not yet peer reviewed) evaluated VE against hospitalization and death among persons 60 years and older during a period when the Mu variant was predominant.³⁰ AstraZeneca-Vaxzevria, Janssen-Ad26.COVS.2, Pfizer BioNTech-Comirnaty, and Sinovac-CoronaVac were 75.4% (48.2-88.3%), 80% (19.9-95.0%), 90.3% (87.1-92.7%), and 67.2% (63.7-70.4%) effective at preventing hospitalization, respectively. The same vaccines were 96.3% (88.4-98.8%), 75.0% (0.0-93.8%), 98.5% (97.8-98.9%), and 77.1% (75.5-78.6%) effective at preventing death, respectively. Maximum possible follow-up time since complete vaccination ranged from 4-11 weeks depending on the vaccine.

“VE” refers to vaccine effectiveness or vaccine efficacy. “Summary of VE”: indicates the general conclusions but only for the vaccines evaluated against the specific variants. **Arrows** generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study. **Subscripts** denote the number of studies informing this table, which may be found on the [VIEW-hub Resource Library](#). **Superscripts** denote article references from randomized controlled trials (RCTs) informing this table.

African Region

Declining trends observed in the Region since mid-July continued this week with over 19 000 new cases and over 700 new deaths reported, decreases of 9% and 13%, respectively, as compared to the previous week. Nevertheless, 17/49 countries (34%) reported increases of over 10% as compared with the previous week, with the largest increases observed in Rwanda (100%), Comoros (94%) and Eritrea (68%). The highest numbers of new cases were reported from Ethiopia (3313 new cases; 2.9 new cases per 100 000 population; a 14% increase), South Africa (2554 new cases; 4.3 new cases per 100 000; a 19% decrease), and Cameroon (2210 new cases; 8.3 new cases per 100 000; a 17% increase).

The highest numbers of new deaths were reported from South Africa (249 new deaths; <1 new death per 100 000 population; a 24% decrease), Ethiopia (118 new deaths; <1 new death per 100 000; a 13% decrease), and Cameroon (86 new deaths; <1 new death per 100 000; a 72% increase).

Updates from the [African Region](#)

Region of the Americas

Declining trends in the Region of the Americas have slowed, with over 734 000 new cases (similar to the previous week) and over 15 000 new deaths (similar to the previous week) reported. Eleven countries in the Region (19%) reported increases in new cases in the past week, with the largest increases observed in the Cayman Islands (145%), Uruguay (38%) and Puerto Rico (21%). The highest numbers of new cases were reported from the United States of America (528 455 new cases; 159.7 new cases per 100 000; a 7% increase), Brazil (81 558 new cases; 38.4 new cases per 100 000; similar to the figures of the previous week), and Mexico (18 880 new cases; 14.6 new cases per 100 000; a 6% decrease).

The highest numbers of new deaths were reported from the United States of America (9550 new deaths; 2.9 new deaths per 100 000; a 6% decrease), Brazil (2323 new deaths; 1.1 new deaths per 100 000; a 6% decrease), and Mexico (1539 new deaths; 1.2 new deaths per 100 000; a 40% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 113 000 new cases, a 12% increase; and over 2300 new deaths, similar to the numbers reported in the previous week. The number of new weekly cases has decreased week on week for almost two months. The highest numbers of new cases were reported from the Islamic Republic of Iran (64 541 new cases; 76.8 new cases per 100 000; an 18% decrease), Jordan (11 060 new cases; 108.4 new cases per 100 000; a 15% increase), and Iraq (9175 new cases; 22.8 new cases per 100 000; a 19% decrease). This week, five of 22 countries in the Region reported increases of over 10% in weekly case incidence.

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1074 new deaths; 1.3 new deaths per 100 000; a 9% decrease), Egypt (350 new deaths; <1 new deaths per 100 000; an 11% increase), and Iraq (201 new deaths; <1 new deaths per 100 000; similar to the numbers of the previous week).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region has continued to report an increasing trend, with nearly 1.8 million new cases and 24 000 new deaths reported this week, a 6% increase and 12% increase, respectively, as compared to the previous week; reaching regional case rates similar to those reported in December 2020. Out of the 61 countries in the Region, 25 (41%) reported increases in cases in the past week. The highest numbers of new cases were reported from the United Kingdom (285 028 new cases; 419.9 new cases per 100 000; a 14% decrease), the Russian Federation (272 147 new cases; 186.5 new cases per 100 000; a 9% increase), and Turkey (182 027 new cases; 215.8 new cases per 100 000; an 8% decrease).

The highest numbers of new deaths were reported from the Russian Federation (7938 new deaths; 5.4 new deaths per 100 000; a 9% increase), Ukraine (3857 new deaths; 8.8 new deaths per 100 000; a 19% increase), and Romania (3072 new deaths; 15.9 new deaths per 100 000; a 6% increase).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 180 000 new cases and over 4900 new deaths, a 9% decrease and a 50% increase, respectively, as compared to the previous week. While weekly case incidence has continued to decrease week on week for over three months, weekly death incidence increased for the second consecutive week. The highest numbers of new cases were reported from India (97 832 new cases; 7.1 new cases per 100 000; a 9% decrease), Thailand (61 542 new cases; 88.2 new cases per 100 000; an 8% decrease), and Myanmar (5810 new cases; 10.7 new cases per 100 000; a 9% decrease).

The highest numbers of new deaths were reported from India (3917 new deaths; 0.3 new deaths per 100 000; an 83% increase), Thailand (450 new deaths; 0.6 new deaths per 100 000; a 7% decrease), and Indonesia (200 new deaths; 0.1 new deaths per 100 000; a 21% decrease). The number of deaths in India accounted for 79% of new weekly deaths in the Region.

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 178 000 new cases, similar to numbers of the previous week, and over 2900 new deaths, a 10% increase as compared to the previous week. The highest numbers of new cases were reported from Malaysia (40 613 new cases; 125.5 new cases per 100 000; similar to the previous week), the Philippines (32 222 new cases; 29.4 new cases per 100 000; a 16% decrease), and Viet Nam (30 708 new cases; 31.5 new cases per 100 000; a 28% increase). These three countries comprised 58% of new weekly cases reported in the Region.

The highest numbers of new deaths were reported from the Philippines (1459 new deaths; 1.3 new deaths per 100 000; a 45% increase), Malaysia (522 new deaths; 1.6 new deaths per 100 000; a 5% increase), and Viet Nam (410 new deaths; 0.4 new deaths per 100 000; a 16% decrease). These three countries comprised 81% of new weekly deaths reported in the Region.

Annexes

Annex 1. Additional notes on VOC impacts on vaccines

- Reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection, as is the case for AstraZeneca-Vaxzevria.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.
- Studies reporting VOC-specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca-Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.

**Newly reported in this update.*

indicates that information for this variant was received by WHO from official sources.

indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

***Includes countries/territories/areas reporting the detection of VOCs among travellers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.*

See also [Annex 3: Data, table and figure notes](#)

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidences, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 63, published 26 October 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on WHO COVID-19 global rapid risk assessment](#)
- [Special Focus: Update on age and sex distribution from WHO COVID-19 global surveillance](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

During the week of 18 to 24 October 2021, the global number of new cases increased slightly (4%) compared to that of the previous week, with just over 2.9 million new cases (Figure 1). The European Region accounted for more than half (57%) of global new weekly cases and was the only region which reported an increase (Table 1). Other regions reported declines in the number of new cases. The largest decrease in new cases was again reported from the African Region (21%), followed by the Western Pacific Region (17%).

The number of new deaths also increased slightly by 5% during the past week, with over 49 000 new deaths reported. Increases were reported in the European (14%) and South-East Asia (13%) regions; whereas the largest declines were observed in the Western Pacific (16%), Eastern Mediterranean (13%) and the African (11%) regions.

As of 24 October, over 243 million confirmed cases and over 4.9 million deaths have been reported since the start of the pandemic.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 24 October 2021**

**See [Annex 2: Data, table and figure notes](#)

The regions reporting the highest weekly case incidence rates per 100 000 population were the European Region (179.1 new cases per 100 000 population) and the Region of the Americas (72.9 new cases per 100 000 population); the same two regions reported the highest weekly incidence in deaths, of 2.3 and 1.8 per 100 000 population, respectively.

The highest numbers of new cases were reported from the United States of America (512 956 new cases; 12% decrease), the United Kingdom (330 465 new cases; 16% increase), the Russian Federation (248 956 new cases; 15% increase), Turkey (196 850 new cases; 8% decrease) and Ukraine (134 235 new cases; 43% increase).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 24 October 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Europe	1 671 245 (57%)	18%	74 963 293 (31%)	21 475 (43%)	14%	1 400 894 (28%)
Americas	745 287 (25%)	-9%	92 891 596 (38%)	18 684 (38%)	1%	2 279 034 (46%)
South-East Asia	197 673 (7%)	-8%	43 782 373 (18%)	3 309 (7%)	13%	687 913 (14%)
Western Pacific	174 271 (6%)	-17%	9 243 232 (4%)	2 684 (5%)	-16%	126 708 (3%)
Eastern Mediterranean	129 949 (4%)	-5%	16 236 262 (7%)	2 420 (5%)	-13%	298 757 (6%)
Africa	21 911 (1%)	-21%	6 131 276 (3%)	841 (2%)	-11%	149 882 (3%)
Global	2 940 336 (100%)	4%	243 248 796 (100%)	49 413 (100%)	5%	4 943 201 (100%)

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to seven days prior

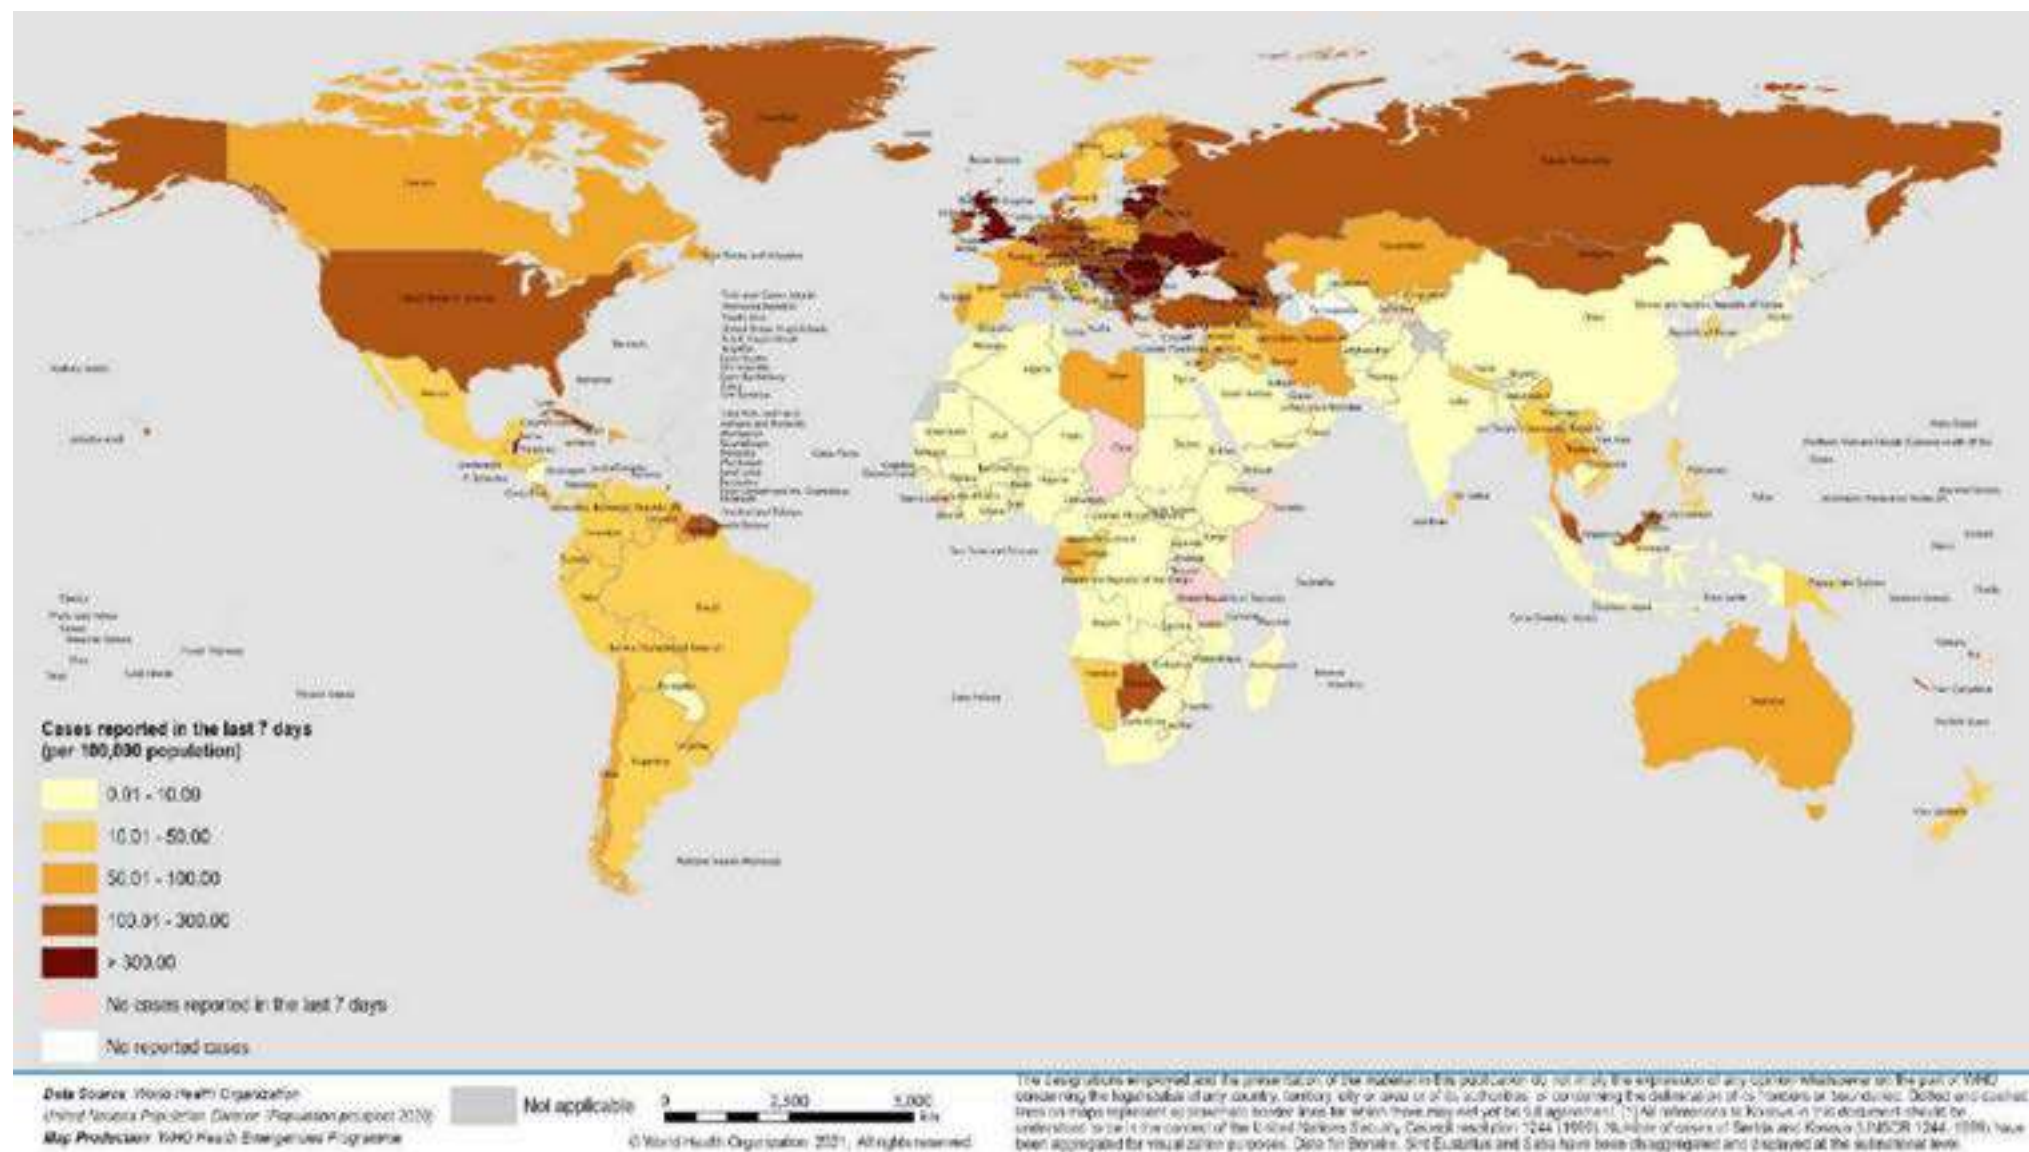

**See [Annex 2: Data, table and figure notes](#)

On 22 October, the ninth meeting of the Emergency Committee was convened by the WHO Director-General under the International Health Regulations (2005) (IHR) regarding the COVID-19 pandemic. The Director-General determined that the COVID-19 pandemic continues to constitute a Public Health Emergency of International Concern (PHEIC). He accepted the advice of the Committee and issued the Committee's advice to States Parties as Temporary Recommendations under the IHR. See the [statement summarising the meeting proceedings and Temporary Recommendations to State Parties](#) for further information.

Special Focus: Update on WHO COVID-19 global rapid risk assessment

The COVID-19 pandemic continues to evolve, as does our understanding of the SARS-CoV-2 virus, and the response needed to control the spread and impact of the virus. In WHO's most recent rapid risk assessment, conducted on 18 October 2021, the global public health risk remains very high.

Under the [Emergency Response Framework](#), WHO undertakes risk assessments and situation analyses on a regular basis to inform our response to emerging situations. In addition, WHO periodically reviews the current risk status of public health events through an in-depth hazard, exposure and context assessment. This also includes a review of the vulnerabilities and capacities available to respond to the public health event and to investigate the current risk to human health, risks of ongoing spread globally, and risk of insufficient control capacities. Such assessments are used as an internal WHO decision-making tool, and to support independent deliberations, including but not limited to meetings of the [International Health Regulations \(IHR 2005\) Emergency Committee regarding the COVID-19 pandemic](#). To date, 12 global rapid risk assessments have been undertaken for COVID-19, and additional assessments have been conducted for specific events such as the emergence of SARS-CoV-2 variants. Here, we provide a synopsis of the most recent in-depth global rapid risk assessment for COVID-19.

While COVID-19 case and death incidence has been decreasing in five out of the six WHO regions (except for the European Region) over a prolonged period, it remains high overall, and numerous countries are experiencing an increase in cases, hospitalizations, and deaths. These increases are due to multiple factors, including high prevalence of variants with increased transmissibility; easing of and/or poor adherence to public health and social measures (PHSM) coupled with increased social mixing and resumption of non-essential travel; reopening of schools; and continued susceptibility of a large proportion of the population due to limited vaccine access and coverage.

The rapid spread of the highly transmissible Delta variant has continued to drive sharp resurgences in the three months since the [last risk assessment](#) in many countries across all six WHO regions. In almost all countries in which Delta has been reported, it has replaced all other variants including other Variants of Concern (VOCs), quickly becoming the dominant circulating variant. These resurgences have come as many countries face considerable pressure to ease PHSM due to the prolonged duration of the pandemic and the impact of restrictions on societies and economies, SARS-CoV-2 evolution and epidemiology, including the impact of known and emerging variants, and may lead to additional challenges in outbreak containment, particularly as many countries move towards further reopening. Easing PHSM without robust surveillance and testing infrastructure, coupled with an increase in the number of regional and global mass gathering events, may increase the risk of new outbreaks and the emergence of additional VOCs. Additionally, as a proportion of all cases, an increase in the number of cases among those aged 0-24 year has been reported, particularly in the European and Western Pacific regions. This trend could be due to older age groups being more likely to be vaccinated, increased social mixing in younger age groups and in-person learning increasing the exposure potential among 0-24-year-olds. In addition, the reopening of schools has been accompanied by increased testing of this age group. However, overall rates of infection and severe disease remain relatively low among children and young adults.

While more than 6 billion COVID-19 vaccines doses have been administered, as of 18 October, less than half (47%) of the world's population have received at least one dose of vaccine. Nearly two-thirds of vaccines administered have been in ten high-income countries, while only 35% have been in low-income or lower-middle-income countries, highlighting ongoing vaccine inequities. The administration of additional/booster doses beyond those recommended by the Strategic Advisory Group of Experts on Immunization (SAGE) in a number of high-income countries further constrains the global vaccine supply and exacerbates the inequalities in vaccine distribution.

Despite improvements in the global supply chain, some countries continue to experience shortages and lack of access to testing, vaccines, medical oxygen, personal protective equipment, and other supplies that are essential to the pandemic response. These shortages place additional pressure on already strained health systems in many countries, which directly impacts the delivery of essential health services globally, including in well-resourced countries. Insufficient funding for the global response is an additional challenge; WHO faces a US\$ 900 million gap in its funding goal, approximately half of the target set in the COVID-19 Strategic Preparedness and Response Plan (SPRP) 2021.

Knowledge gaps remain, including the phenotypic impact of identified and emerging variants, details on waning immunity, and further characterization of the post-COVID-19 condition. In addition, further investigations are required to determine whether there are any changes in the severity profile those infected with VOCs, including children and adolescents.

Special Focus: Update on age and sex distribution from WHO COVID-19 global surveillance

WHO has been supporting global COVID-19 epidemiological surveillance since January 2020. In addition to the daily count of confirmed cases and deaths, WHO requested Member States to report a minimal set of information via a case-based reporting system, using a [case reporting form](#) (CRF) or via the [weekly aggregated reporting system](#). Weekly aggregate surveillance data include the number of cases and deaths disaggregated by age groups and sex, health care workers status, the number of hospitalizations, recoveries, and tests performed.

As of 12 October 2021, over 20 months since the beginning of the pandemic, a total of 184 countries, territories and areas have shared detailed information on 167 million COVID-19 cases, representing over 70% of reported cases, globally. The completeness of these data varies by region (Figure 4), and among income categories, with data being less complete for lower-income countries. Regarding information on COVID-19 mortality, 184 countries reported 1 934 548 deaths to this case-based reporting system, representing less than 40% of the number of deaths reported globally.

Figure 4. Data completeness by WHO region, data as of 12 October 2021 (n=237 973 361)

Distribution by age and sex

Data on sex was reported for 122 921 974 cases, representing 52% of global cases. Of these, 51% (n=62 191 734) were female. However, males accounted for a larger proportion of deaths, 58% (n=1 201 236). These ratios vary by region, for example, in the Eastern Mediterranean and African regions, there is a greater proportion of males in both cases and in deaths.

Age was reported from a total of 99 067 915 cases, representing 40% of global cases (Figure 5). Since the beginning of July 2021, an increase in the proportion of cases among those aged 0-24 years began to has been observed (Figure 6), especially in the European and Western Pacific regions. This is likely due in part to the prioritization of older age groups for vaccination in most countries. Additionally, resumption of in-person schooling, together with the implementation of strengthened testing strategies among children and young people, may also have contributed to the observed increase in reported cases among those aged 0-24 years. However, overall rates of infection and disease remain low among children and young adults.

Figure 5: Distribution by age of confirmed COVID-19 cases per week, COVID-19 WHO surveillance, January 2020 to 12 October 2021 (n=99 067 915)

Figure 6: Proportion by age of confirmed COVID-19 cases per week, COVID-19 WHO surveillance, January 2020 to 12 October 2021 (n=99 067 915)

Trends in age-specific case fatality ratios (CFR)

Figure 7 shows CFRs by age-group and year-quarter. Among those aged under 64 years, the CFR has remained below 2.5% throughout the pandemic. Since the second quarter of 2020 (April-September), the CFR substantially decreased among those aged 65 years and over, declining from 26% in the second quarter of 2020, to 5% in the third quarter of 2021, likely as result of the implementation of targeted COVID-19 preventive measures including but not limited to vaccination in this age group as well as the improvements in clinical care over time.

Figure 7. COVID-19 Case fatality ratio (CFR) by age group and quarter, 2020 to 2021 Quarter 3, as of 12 October 2021

Conclusions and recommendations

Data submitted to the WHO has highlighted differences in the proportion of COVID-19 cases by age groups and sex, including a recent surge of cases in younger age groups (0-24 years-old), although these proportions are not evenly distributed worldwide. The CFR in people over 65 years has dropped to below 5% recently, which may be due to several factors including, but not limited to, non-pharmaceutical interventions, improved clinical understanding and management of COVID-19, and the impact of vaccination.

Despite the great effort in COVID-19 surveillance being made by Member States, there is still room for improvement. The completeness of surveillance data is still low and varies regionally and among income categories, with lower-income countries reporting less complete data. WHO recommends ongoing surveillance for COVID-19 in order to understand the incidence and mortality among different age groups, which populations are at higher risk for severe disease and death, and potential epidemiological changes over time.

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As evidence becomes available, classification for VOIs or VOCs will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification and the current lists of VOCs, VOIs and other Variants Under Monitoring are available on the [WHO Tracking SARS-Cov-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

As these risks evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website). The prevalence of different variants is being monitored in light of other co-circulating variants, such as Delta. The global distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries, and delays in reporting.

Geographic spread and prevalence of VOCs

The current global genetic epidemiology is characterized by a predominance of Delta variant, with declining prevalence of other variants among SARS-CoV-2 sequences submitted to publicly available datasets or reported to WHO (Figure 5, Annex 1). Delta has outcompeted other variants, including other VOCs, in most countries. However, sub-regional and country-level variation continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual, and other variants (e.g. Gamma, Mu) still contribute a large proportion of sequences.

Global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities, sampling strategies between countries and delays in reporting. Current efforts are underway to strengthen genomic surveillance in several regions and countries to enhance coverage of sequencing and detection of variants globally.

Lineage AY.4.2

With ongoing spread and evolution of SARS-CoV-2, new branches of the COVID-19 evolutionary tree continue to be defined, including within the Delta VOC. The characterization of Pango lineages and Nextstrain clades, together with other genomic systems and tools, assists researchers and public health agencies worldwide to track the evolution of SARS-CoV-2. [Nextstrain](#) has recently identified two additional subclades of Delta that have grown in frequency globally, and therefore currently divides the Delta variant into 3 clades: 21A, 21I, 21J. As per the latest [Pango nomenclature](#), which is more fine-scaled, 67 lineages have been designated within Delta. Each of the three Nextstrain clades (21A, 21I and 21J) correspond to multiple Pango AY lineages. New lineages are regularly assigned as new sequencing data becomes available and processed to define epidemiologically relevant phylogenetic clusters, e.g. an introduction into a district geographic area with evidence of onward transmission.¹ Past sequences and associated metadata are also retrospectively updated, which should be taken into account when interpreting GISAID data. WHO, in collaboration with the SARS-CoV-2 Virus Evolution Working Group, continues to monitor and assess SARS-CoV-2 variants, including the AY lineages within Delta VOC.

AY.4.2 is a newly designated Pango lineage within Delta VOC, which has three additional mutations, including two in the spike protein: A222V and Y145H. An increase in AY.4.2 sequence submissions has been observed since July 2021, and as of 25 October, over 26 000 AY.4.2 sequences have been uploaded to GISAID from 42 countries. The majority (93%) of these sequences were reported from the United Kingdom, where a gradual increase in the proportional contribution of AY.4.2 has been observed; accounting for an estimated 5.9% of overall Delta cases reported in the week beginning 3 October 2021.² Epidemiological and laboratory studies are ongoing to assess if AY.4.2 confers any additional phenotypic impacts (e.g. a change in transmissibility or a decrease in the ability of antibodies to block the virus).

African Region

The declining trend observed in the African Region since mid-July continued this week with over 22 000 new cases and over 800 new deaths reported, a decrease of 21% and 11% respectively as compared to the previous week. While this is reassuring, ten out of the 49 countries (20%) in the Region reported increases in new weekly cases as compared with the previous week, with the greatest increase observed in Réunion (578%), Botswana (116%), and Gambia (100%). The highest numbers of new cases were reported from South Africa (3153 new cases; 5.3 new cases per 100 000 population; a 33% decrease), Botswana (3063 new cases; 130.3 new cases per 100 000; a 116% increase), and Ethiopia (2908 new cases; 2.5 new cases per 100 000; a 38% decrease).

The highest numbers of new deaths were reported from South Africa (327 new deaths; <1 new death per 100 000 population; an 11% increase), Ethiopia (136 new deaths; <1 new death per 100 000; a 45% decrease), and Nigeria (52 new deaths; <1 new death per 100 000; a 12% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 745 000 new cases this week, a 9% decline as compared to the previous week and a continuation of the declining trend in the region observed since the end of August 2021. Nevertheless, 25% of countries (14/56) reported an increase in new cases this week as compared to the previous week, with the largest increases observed in Dominica (166%), Cayman Islands (156%) and Paraguay (136%). The highest numbers of new cases were reported from the United States of America (512 956 new cases; 155.0 new cases per 100 000; a 12% decrease), Brazil (84 367 new cases; 39.7 new cases per 100 000; a 10% increase), and Mexico (32 940 new cases; 25.5 new cases per 100 000; a 7% decrease).

Deaths remain stable as compared with the previous week, with the highest numbers of new deaths reported from the United States of America (11 604 new deaths; 3.5 new deaths per 100 000; similar to the number reported last week), Brazil (2470 new deaths; 1.2 new deaths per 100 000; a 10% increase), and Mexico (2324 new deaths; 1.8 new deaths per 100 000; similar to the number reported last week).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The number of cases and deaths continued to decline this week in the Eastern Mediterranean Region, with just under 130 000 new cases and over 2400 new deaths reported, a 5% and a 13% decrease respectively as compared to the previous week. This declining trend in both cases and deaths has been observed since late July 2021. In the past week, just under one third of the countries (6/22; 27%) in the region reported an increase in new cases and the highest increases were observed in Sudan (57%) and the Syrian Arab Republic (26%). The highest numbers of new cases were reported from the Islamic Republic of Iran (78 251 new cases; 93.2 new cases per 100 000; similar to the number reported in the previous week), Iraq (11 290 new cases; 28.1 new cases per 100 000; similar to the number reported in the previous week), and Jordan (9641 new cases; 94.5 new cases per 100 000; a 25% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1176 new deaths; 1.4 new deaths per 100 000; a 22% decrease), Egypt (316 new deaths; <1 new death per 100 000; an 18% increase), and Iraq (199 new deaths; <1 new death per 100 000; similar to the number reported in the previous week).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 1.6 million new cases and over 21 000 new deaths, an 18% and a 14% increase respectively compared to the previous week. The trend observed since the end of September continued this week with an increasing number of new cases and deaths reported in the Region. More than half (42/61; 69%) of the countries in the European Region reported an increase in cases in the past week. The highest numbers of new cases were reported from the United Kingdom (330 465 new cases; 486.8 new cases per 100 000; a 16% increase), the Russian Federation (248 956 new cases; 170.6 new cases per 100 000; a 15% increase), and Turkey (196 850 new cases; 233.4 new cases per 100 000; an 8% decrease).

The highest numbers of new deaths were reported from the Russian Federation (7288 new deaths; 5.0 new deaths per 100 000; a 6% increase), Ukraine (3239 new deaths; 7.4 new deaths per 100 000; a 51% increase), and Romania (2889 new deaths; 14.9 new deaths per 100 000; a 22% increase).

Updates from the [European Region](#)

South-East Asia Region

Since the end of July 2021, new weekly cases continue to decline in the Region, with 197 000 new cases reported this week, an 8% decrease as compared with the previous week. All the countries reported a decreasing trend except for Maldives (23% increase), Timor-Leste (37% increase) and Nepal (42% increase). The highest numbers of new cases were reported from India (107 749 new cases; 7.8 new cases per 100 000; a 6% decrease), Thailand (66 781 new cases; 95.7 new cases per 100 000; an 8% decrease), and Myanmar (6410 new cases; 11.8 new cases per 100 000; a 30% decrease).

On the other hand, new weekly deaths increased by 13% this week as compared with the previous week, largely driven increases in India (40% increase) and Nepal (21% increase). The highest numbers of new deaths were reported from India (2145 new deaths; <1 new death per 100 000; a 40% increase), Thailand (482 new deaths; <1 new death per 100 000; a 17% decrease), and Indonesia (253 new deaths; <1 new death per 100 000; a 16% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 174 000 new cases and over 2600 new deaths, a 17% and a 16% decrease respectively, as compared to the previous week. Despite the ongoing declining trends in the Region, of the countries reporting cases (19/26; 73%), more than a quarter (5/19; 26%) still reported increases in new cases in the past week. The highest numbers of new cases were reported from Malaysia (41 508 new cases; 128.2 new cases per 100 000; a 21% decrease), the Philippines (38 189 new cases; 34.8 new cases per 100 000; a 35% decrease), and Singapore (24 141 new cases; 412.6 new cases per 100 000; a 15% increase).

The highest numbers of new deaths were reported from the Philippines (1005 new deaths; <1 new death per 100 000; a 7% decrease), Malaysia (496 new deaths; 1.5 new deaths per 100 000; a 16% decrease), and Viet Nam (489 new deaths; <1 new death per 100 000; a 29% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 25 October, highlights include the following:

- Rapid Response Mobile Laboratory (RRML/GOARN) initiative strengthens international RRML deployment capabilities
- PAHO and US Centers for Disease Control and Prevention Partner to Bolster COVID-19 Response in Jamaica
- Leveraging polio campaign to integrate COVID-19 vaccination in Nigeria
- HealthBuddy+ in Bulgaria: innovative COVID-19 chatbot supports mental health during the pandemic
- Online courses support rollout of Go.Data outbreak investigation tool
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

*Newly reported in this update.

indicates that information for this variant was received by WHO from official sources.

indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table and figure notes](#)

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 62, published 19 October 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 17 October 2021

With just over 2.7 million new cases and over 46 000 new deaths reported during the week of 11 to 17 October 2021, the global number of new cases and deaths remained similar to that of the previous week (Figure 1). Apart from the European Region, which reported a 7% increase in the number of new weekly cases when as compared to the previous week, all the other regions reported declines in new weekly cases (Table 1). The largest decrease in new weekly cases was reported from the African Region (18%), followed by the Western Pacific Region (16%). The cumulative number of confirmed cases reported globally is now over 240 million and the cumulative number of deaths is just under 4.9 million.

The African Region also reported the largest decline in weekly deaths (25%) followed by the South-East Asia and Eastern Mediterranean Regions with 19% and 8% declines, respectively. All other regions reported new deaths in numbers similar to those of the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 17 October 2021**

**See [Annex 3: Data, table and figure notes](#)

The regions reporting the highest weekly case incidence rates per 100 000 population were the European Region (145.6 new cases per 100 000 population) and the Region of the Americas (79.9 new cases per 100 000 population); the same two regions reported the highest weekly incidence in deaths, of 1.9 and 1.8 per 100 000 population, respectively.

The highest numbers of new cases were reported from the United States of America (582 707 new cases; 11% decrease), the United Kingdom (283 756 new cases; 14% increase), the Russian Federation (217 322 new cases; 15% increase), Turkey (213 981 new cases; similar to the number reported in the previous week) and India (114 244 new cases; 18% decrease).

Globally, three additional countries, territories or areas (hereafter countries) reported cases with VOCs in the past week. As of 19 October, cases of Alpha variant have been reported from 196 countries (one new country added), Beta variant from 145 countries (no new country added), Gamma variant from 99 countries, and Delta variant from 193 countries (two new countries added) across all six WHO regions.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 17 October 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Africa	27 606 (1%)	-18%	6 109 365 (3%)	940 (2%)	-25%	149 041 (3%)
Americas	816 860 (30%)	-14%	92 142 897 (38%)	18 322 (40%)	-1%	2 260 259 (46%)
Eastern Mediterranean	136 074 (5%)	-6%	16 106 313 (7%)	2 769 (6%)	-8%	296 337 (6%)
Europe	1 358 284 (49%)	7%	73 226 218 (30%)	17 998 (39%)	4%	1 378 412 (28%)
South-East Asia	214 984 (8%)	-13%	43 584 700 (18%)	2 933 (6%)	-19%	684 604 (14%)
Western Pacific	210 149 (8%)	-16%	9 068 961 (4%)	3 178 (7%)	1%	124 024 (3%)
Global	2 763 957 (100%)	-4%	240 239 218 (100%)	46 140 (100%)	-2%	4 892 690 (100%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As evidence becomes available, classification for VOIs or VOCs will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology. Criteria for variant classification and the current lists of VOCs, VOIs and other Variants Under Monitoring (VUMs) are available on the [WHO Tracking SARS-CoV-2 variants website](#). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

Geographic spread and prevalence of VOCs

The current global genetic epidemiology is characterized by a predominance of Delta variant, with declining prevalence of other variants among SARS-CoV-2 sequences submitted to publicly available datasets (Figure 4). Given its higher transmissibility, Delta has outcompeted other variants, including other VOCs, in many countries. Important sub-regional and country-level variation, nevertheless, continues to be observed; most notably within some South American countries, where the progression of the Delta variant has been more gradual than that observed in other regions, and other variants (e.g. Gamma, Mu) still contribute a large proportion of sequences samples.

To better reflect recent changes and the current geographic distribution of VOCs at a global level, we present here a revised set of global maps overlaying recent estimates of VOC prevalence, with data previously presented on detection of VOC reported officially or unofficially to WHO (Figure 5). Country-specific prevalence estimates were calculated as a proportion of total SARS-CoV-2 sequences uploaded to GISAID with a specimen collection date within the past 60 days, summarised into three groups to illustrate locations where the prevalence of VOCs is currently: dominant (>50% prevalence), moderate (11-50% prevalence) or low ($\leq 10\%$). To ensure robustness of estimates, proportion estimates were limited to countries with 100 or more sequences uploaded during the reporting period. For countries with fewer than 100 sequences submitted, data on the detection or absence of submitted VOCs sequences, as well as previous reports of VOC detection are shown, and are detailed in Annex 2. Overall, these maps further highlight that in recent months, Delta is the most prevalent variant with widespread global circulation. Other VOCs and other variants are still circulating in some countries, however, largely at low levels.

Global VOCs distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities, sampling strategies between countries and delays in reporting. Current efforts are underway to strengthen genomic surveillance for SARS-CoV-2, including variants, in several regions and countries to enhance coverage of sequencing and detection of variants globally.

Figure 4: Proportion of current global VOC or VOI sequences reported among total sequences submitted over time by WHO Region, 1 August 2020 – 15 October 2021*

*Data source: [GISAID Initiative](#)

Alpha

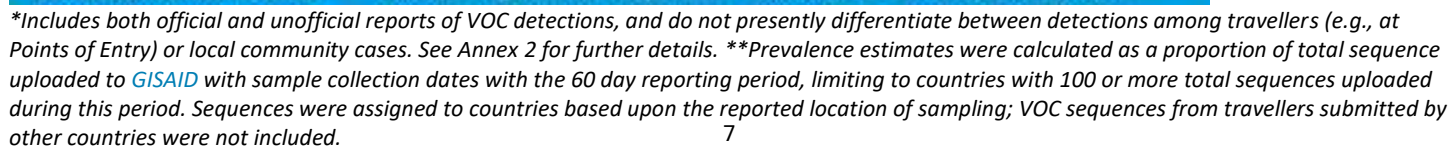

Proportion of VOC among total sequences (countries with ≥ 100 sequences in last 60 days)

- 0.51 - 1.00
- 0.11 - 0.50
- $\leq 0.00 - 0.10$

VOC selected: too few sequences to estimate proportion

No new VOC sequences: VOC previously reported

No presence of VOC reported to WHO

Gamma

Delta

*Includes both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. See Annex 2 for further details. **Prevalence estimates were calculated as a proportion of total sequence uploaded to [GISAID](#) with sample collection dates with the 60 day reporting period, limiting to countries with 100 or more total sequences uploaded during this period. Sequences were assigned to countries based upon the reported location of sampling; VOC sequences from travellers submitted by other countries were not included.

Phenotypic characteristics

Available evidence on the phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of the COVID-19 Weekly Epidemiological Updates. Since the last detailed update on 5 October, there are several new publications on the phenotypic characteristics of VOCs.

A prospective study, not yet peer reviewed, assessed the illness profiles (symptom prevalence, duration and burden), hospital presentation, and presence of long (≥ 28 days) illness among 1400 symptomatic school-aged children in two groups (younger children aged 5–11 years and older children aged 12–17 years) who tested positive for SARS-CoV-2. The study was conducted in the United Kingdom at a time when either Alpha (28 December 2020 to 6 May 2021) or Delta (26 May to 8 July 2021) were the predominant circulating SARS-CoV-2 variant.¹ Findings from the study suggested that disease in school-aged children due to Delta variant resembles illness due to the Alpha variant, with short duration and similar symptom burden. Median illness duration was short with either variant: 5 days (IQR 2–9.75) with Alpha, and 5 days (IQR 2–9) with Delta. The median symptom burden (number of symptoms) over the entire period of illness (28 days) was slightly greater among children infected with Delta compared to Alpha infection (in younger children, 3 (IQR 2–5) with Alpha, 4 (IQR 2–7) with Delta; in older children 5 (IQR 3–8) with Alpha and 6 (IQR 3–9) with Delta infection. The seven most prevalent symptoms were common to both variants and included headache, fatigue, fever, dysosmia (disordered smell perception), sneezing, rhinorrhoea, and sore throat; suggesting no meaningful clinical differences in the disease presentation with either variant. Only a small number of children infected with either variant presented to the hospital, and the presence of long (≥ 28 days) illness was reported to be low.

Findings in another pre-print study conducted in Indonesia², among adults, evaluated the impact of Delta variant versus non-Delta variant infections on the outcomes of COVID-19 patients. The study included 69 cases with confirmed isolation of the Delta variant compared with 92 cases of non-Delta variant. Analysis of associated individual variables showed no significant differences in hospitalization or mortality between patients with Delta and non-Delta variant infections ($p=0.80$ and 0.29 , respectively). Additionally, multivariate analysis suggested that age ≥ 65 years (OR 11.5; 95% CI 1.3–102.6; $P=0.028$), obesity (OR 16.6; 95% CI 2.5–107.1; $p=0.003$), diabetes (OR 5.5; 95% CI 1.3–23.7; $p=0.021$), and hypertension OR 5.8; 95% CI 1.02–32.8; $p=0.047$), were prognostic factors for mortality in both groups. Conversely, no prognostic factors were found to be associated with the hospitalization of COVID-19 patients.

A peer-reviewed retrospective study³ conducted in Ireland, analysed the effect of SARS-CoV-2 infection during pregnancy, and the impact of Alpha variant on neonatal clinical outcomes. The study included all liveborn neonates from mothers who tested positive for SAR-CoV-2 at any time during pregnancy and up to 24 hours post-partum. This included 133 neonates who were delivered between 1 March 2020 and 1 March 2021, of which 66 (49.6%) were born following maternal SARS-CoV-2 infection after 1 January 2021, corresponding to a time when Alpha was the dominant variant in circulation in Ireland. The findings suggested no increase in the incidence of preterm birth or neonatal intensive care unit admission when compared with 5-year, pre-pandemic hospital data. Maternal infection before and after Alpha variant circulation or maternal symptom status also did not influence neonatal outcomes. While this is a reassuring initial finding, further studies to evaluate the impact of VOC infections during pregnancy, particularly the Delta variant, are required.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility ⁴	Increased transmissibility ^{5,6}	Increased transmissibility ^{6,7}	Increased transmissibility ^{6,8,9}
Disease severity	Possible increased risk of hospitalization ^{10,11} , possible increased risk of severe disease and death ^{12,13}	Possible increased risk of hospitalization ¹¹ , possible increased in-hospital mortality ¹⁴	Possible increased risk of hospitalization ¹¹ , possible increased risk of severe disease ¹⁵	Possible increased risk of hospitalization ^{16,17}
Risk of reinfection	Neutralizing activity retained ¹⁸ , risk of reinfection remains similar ¹⁹	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²⁰	Moderate reduction in neutralizing activity reported ²¹	Reduction in neutralizing activity reported ^{22–24}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF), no impact on overall result from multiple target RT-PCR; No impact on Ag RDTs observed ²⁵	No impact on RT-PCR or Ag RDTs observed ²⁴	None reported to date	No impact on RT-PCR or Ag RDTs ²⁶ observed

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

Table 3 presents the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to VE in non-VOC settings. Of note, reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection, as is the case for AstraZeneca-Vaxzevria.

Table 3. Summary of vaccine performance against Variants of Concern

VE refers to vaccine effectiveness and vaccine efficacy

⁺As of submission of this update

*Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant

Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used.

“Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the VIEW-hub Resources page (<https://view-hub.org/resources>). For individual vaccine effectiveness studies, see ‘COVID-19 Vaccine Effectiveness Results Summary’, reference numbers noted with a ‘#’. For a list of all neutralization studies, see ‘COVID-19 Vaccine Neutralization Studies Table’.

References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table and are included in the Annex-1.

Since the [5 October update](#), four notable new studies have provided evidence of COVID-19 vaccine performance after full vaccination against Variants of Concern.

A test-negative case control study from the United States of America (not yet peer reviewed) evaluated the effectiveness of Moderna-mRNA-1273 against SARS-CoV-2 infection among members (4.6 million) of a large healthcare system in Southern California aged 18 years and older³⁴. A total of 8, 153 cases were included in the study and 5 controls were matched to each case. Vaccination with Moderna-mRNA-1273 was found to be highly effective at preventing SARS-CoV-2 infection due to Delta 14-60 days post second dose (VE: 94.1%, 95% CI: 60.5-96.3), but declined to 80.0% (95% CI: 70.2-86.6%) at 151-180 days post second dose. VE against infection due to non-Delta variants showed a similar pattern with a VE against infection 14-60 days post second dose of 98.6% (97.3-99.3%) which reduced to 88.7% (73.2-95.2%) at 121-150 days.³⁴ VE against hospitalization due to Delta over the entire study period (≥ 14 days post second dose) was 97.6% (92.8-99.2%). VE estimates against infection over the entire study period (≥ 14 days post second dose) were 98.4% (96.9-99.1%), 95.5% (90.9-97.8%), and 90.4% (73.9-96.5%) for Alpha, Gamma, and Mu variants, respectively.

A second study from Canada (not yet peer-reviewed) provided updated results from a previous version of the pre-print.³⁵ The study evaluated VE of Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273, and AstraZeneca-Vaxzevria vaccines against symptomatic disease and against hospitalization or death due to Alpha, Beta, Gamma, and Delta VOCs. All vaccines were highly effective at preventing both symptomatic disease as well as hospitalization or death 14 or more days post final vaccination (two doses). VE against symptomatic disease was $\geq 86\%$ for each vaccine and against each VOC. VE against hospitalization or death was $\geq 92\%$ for each vaccine against each VOC. These estimates include a follow-up time post full vaccination of up to 28 weeks, 25 weeks, and 3 weeks for Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273, and AstraZeneca-Vaxzevria vaccines, respectively. Of note, VE of AstraZeneca-Vaxzevria against hospitalization or death due to Beta was not reported; several VE estimates were approximated to be 100% but could not be reliably assessed due to no cases in the vaccinated group.

A third peer-reviewed study from Spain, assessed the effectiveness of Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273, AstraZeneca-Vaxzevria and Janssen-Ad26.COV 2.S vaccines in preventing SARS-CoV-2 infection due to Alpha and Delta variants based on the vaccine status of close contacts of index cases³⁶. Moderna-mRNA-1273, Janssen-Ad26.COV 2.S Pfizer BioNTech-Comirnaty, and AstraZeneca-Vaxzevria were found to be 86% (56-95%), 77% (27-93%), 71% (61-78%), and 38% (-42-73%) effective at preventing infection among close contacts due to Alpha 14 or more days post final dose, respectively, with follow-up time since complete vaccination up to 28, 23, 31 and 16 weeks for each of the vaccines, respectively. VE against infection due to Delta was similar to Alpha for the mRNA vaccines [67% (59-74%) for Pfizer BioNTech-Comirnaty, 77% (63-85%) for Moderna-mRNA-1273]. However, VE against Delta infection was lower for Janssen-Ad26.COV2.S at 42% (18-59%) than that against Alpha, although with very wide confidence intervals for both VE estimates. The VE of AstraZeneca-Vaxzevria against Delta was 55% (39-67%); comparison to that of Alpha is hindered due to the very small numbers with Alpha infection. This study also evaluated the VE of one dose of AstraZeneca-Vaxzevria followed by a second dose of Pfizer BioNTech-Comirnaty vaccine against infection due to Delta. VE of this heterologous regimen against Delta infection 14 or more days post second dose was 86% (45-97%), with a follow-up time up to 21 weeks post full vaccination. The lower VE estimates from this study compared to estimates from other studies can possibly be explained by the fact that close contacts of index cases face frequent exposure and are, therefore, at higher risk of becoming infected even if vaccinated.

A fourth study from Israel (not yet peer reviewed) evaluated the effectiveness of a booster dose of Pfizer BioNTech-Comirnaty at preventing infection, severe disease, and death compared to two doses of the same vaccine during a time when Delta was the predominant variant³⁷. Protection against confirmed infection was lower among individuals receiving a third booster dose relative to those who received two doses of the vaccines 5 or more months prior by a factor of 8.8-17.6 depending on age group. The rate of severe disease among individuals 60 years and older was 18.7-fold (95% CI 15.7-22.4) lower in the group who received a booster dose, as compared to the group who did not receive a booster dose, and among individuals 40-59 years old, was 22-fold (95% CI 10.3-47) lower. Among persons 60 years and older, the rate of death was lower in the group who received a booster dose by a factor of 14.7 (9.4-23.1) compared to the group who did not receive a booster dose. Follow up time post-booster ranged from 3.5 weeks for individuals 16-29 years to 8 weeks for persons 60 years and older.

WHO, with support of the Strategic Advisory Group of Experts (SAGE) on Immunization and its COVID-19 Vaccines Working Group, continues to review the emerging evidence on the need for and timing of a booster dose for the currently available COVID-19 vaccines which have received Emergency Use Listing (EUL). As concluded in the [Interim Statement released 4 October 2021](#), introducing booster doses should be firmly evidence-driven and targeted to the population groups in greatest need. The rationale for implementing booster doses should be guided by evidence on waning vaccine effectiveness, in particular a decline in protection against severe disease in the general population and in high-risk populations, or due to a circulating VOC. To date, the evidence remains limited and still inconclusive on any widespread need for booster doses following a primary vaccination series. In the context of ongoing global vaccine supply constraints, broad-based administration of booster doses risks exacerbating inequities in vaccine access by driving up demand and diverting supply while priority populations in some countries, or in subnational settings, have not yet received a primary vaccination series. Focus remains on urgently increasing global vaccination coverage with the primary series driven by the objective to protect against severe disease.

WHO regional overviews Epidemiological week 11-17 October 2021

African Region

The declining trend observed in the African Region since mid-July continued this week with over 27 000 new cases and over 900 new deaths reported, decreases of an 18% and a 25% decrease respectively as compared to the previous week. While this is reassuring, 13/49 countries (28%) in the Region reported increases of over 15% in the number of reported cases the past week. One third of the new weekly cases in the Region was reported by two countries: Ethiopia and South Africa. The highest numbers of new cases were reported from Ethiopia (4706 new cases; 4.1 new cases per 100 000 population; a 22% decrease), South Africa (4682 new cases; 7.9 new cases per 100 000; a 20% decrease), and Cameroon (3003 new cases; 11.3 new cases per 100 000; similar to previous week).

The highest numbers of new deaths were reported from South Africa (295 new deaths; <1 new death per 100 000 population; a 45% decrease), Ethiopia (247 new deaths; <1 new death per 100 000; a 10% decrease), and Nigeria (59 new deaths; <1 new death per 100 000; a 181% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 816 000 new cases this week a 14% decline as compared to the previous week and a continuation of the declining trend in the region witnessed since the end of August. A small proportion (9/56; 16%) of the countries in the Region of the Americas reported increases in new cases in the past week. Just over 18 000 new deaths were reported this week, a similar incidence as compared to the previous week. The highest numbers of new cases were reported from the United States of America (582 707 new cases; 176.0 new cases per 100 000; an 11% decrease), Brazil (76 746 new cases; 36.1 new cases per 100 000; a 27% decrease), and Mexico (35 468 new cases; 27.5 new cases per 100 000; a 17% decrease).

The highest numbers of new deaths were reported from the United States of America (11 158 new deaths; 3.4 new deaths per 100 000; a 23% increase), Mexico (2398 new deaths; 1.9 new deaths per 100 000; a 34% decrease), and Brazil (2244 new deaths; 1.1 new deaths per 100 000; a 30% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 136 000 new cases and over 2700 new deaths, a 6% and an 8% decrease respectively as compared to the previous week. This follows the decline observed since mid-August 2021. While most of the countries (15/22; 68%) reported a decrease in new weekly cases, Sudan and Afghanistan reported the largest increase as compared to the previous week (22% and 34%, respectively). The highest numbers of new cases were reported from the Islamic Republic of Iran (81 785 new cases; 97.4 new cases per 100 000; similar numbers as those reported last week), Iraq (11 628 new cases; 28.9 new cases per 100 000; a 22% decrease), and Jordan (7718 new cases; 75.6 new cases per 100 000; an 8% increase).

The majority of the countries (17/22; 77%) in the Region reported a decline in new weekly deaths last week as compared to the previous week, with the exception of Afghanistan and Libya that reported an increase of 89% and 11%, respectively. The highest numbers of new deaths were reported from the Islamic Republic of Iran (1506 new deaths; 1.8 new deaths per 100 000; similar numbers as those reported last week), Egypt (268 new deaths; <1 new death per 100 000; similar numbers as those reported last week), and Iraq (201 new deaths; <1 new death per 100 000; similar numbers as those reported last week's).

Updates from the [Eastern Mediterranean Region](#)

European Region

For the third consecutive week the European Region has shown an increase in new weekly COVID-19 cases, with over 1.3 million new cases reported during this week, a 7% increase as compared with the previous week. Over half of the countries in the Region (35/61; 57%) showed an increase in the number of new weekly cases. The highest numbers of new cases were reported from the United Kingdom (283 756 new cases; 418.0 new cases per 100 000; a 14% increase), the Russian Federation (217 322 new cases; 148.9 new cases per 100 000; a 15% increase), and Turkey (213 981 new cases; 253.7 new cases per 100 000; similar to last week's figures).

Over 18 000 new deaths have been reported in the Region; a similar rate to that of the previous week (4%). The largest increase in deaths has been observed in Luxembourg (200%), Denmark (83%) and Slovakia (82%). The highest numbers of new deaths were reported from the Russian Federation (6897 new deaths; 4.7 new deaths per 100 000; a 6% increase), Romania (2360 new deaths; 12.2 new deaths per 100 000; a 27% increase), and Ukraine (2140 new deaths; 4.9 new deaths per 100 000; a 25% increase).

Updates from the [European Region](#)

South-East Asia Region

Declining trends continued in the South-East Asia Region, with just under 215 000 new cases and over 2900 new deaths reported, decreases of 13% and 19% respectively as compared to the previous week. All countries in the Region reported a decline in new cases and deaths this week, apart from Thailand that reported a similar number of cases as compared to the previous week. The highest numbers of new cases were reported from India (114 244 new cases; 8.3 new cases per 100 000; an 18% decrease), Thailand (72 817 new cases; 104.3 new cases per 100 000; a similar number as those reported last week), and Myanmar (9202 new cases; 16.9 new cases per 100 000; a 10% decrease).

The highest numbers of new deaths were reported from India (1535 new deaths; <1 new death per 100 000; a 13% decrease), Thailand (582 new deaths; <1 new death per 100 000; a 14% decrease), and Indonesia (301 new deaths; <1 new death per 100 000; a 37% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Declining trends continued in the Western Pacific Region, with over 201 000 new cases reported this week, a 16% decrease as compared to the previous week. Most of the countries (19/26; 73%) reported a decrease in new weekly cases this week. The highest numbers of new cases were reported from the Philippines (59 052 new cases; 53.9 new cases per 100 000; a 20% decrease), Malaysia (52 321 new cases; 161.7 new cases per 100 000; an 18% decrease), and Viet Nam (24 726 new cases; 25.4 new cases per 100 000; a 25% decrease).

The weekly number of deaths also continue to decline, with over 3100 new deaths reported this week, a 16% decrease as compared to the previous week. Nevertheless, 13% (8/26 countries) reported an increase in new deaths this week as compared to the previous week, with Papua New Guinea reporting a 481% increase. The highest numbers of new deaths were reported from the Philippines (1075 new deaths; 1.0 new death per 100 000; a 27% increase), Viet Nam (689 new deaths; <1 new death per 100 000; an 18% decrease), and Malaysia (593 new deaths; 1.8 new deaths per 100 000; a 15% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) Monitoring and Evaluation team, which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework, and to highlight country-level actions and WHO support to countries. In this week's edition published on 18 October, highlights include:

- Ongoing COVID-19 vaccine rollout in Ghana
- COVID-19 response at mental health care facilities in Azerbaijan
- Two-day vaccination campaign to boost coverage in Samoa
- IT equipment and supplies for vaccine safety surveillance in Belize
- A review of the COVID-19 response in Somalia
- Six in seven COVID-19 infections go undetected in Africa: initiative to enhance community screening
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

Annex

Annex 1. Additional notes on VOC impacts on vaccines

- Studies reporting VOC-specific vaccine efficacy or effectiveness (VE) estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates for these outcomes, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than 4 months post final dose.

*Newly reported in this update.

indicates that information for this variant was received by WHO from official sources.

indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community).

Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

-Kindly note that Delta has been discarded for Syrian Arab Republic upon verification.

See also [Annex 3: Data, table and figure notes](#)

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

COVID-19 Weekly Epidemiological Update

Edition 61, published 13 October 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 10 October 2021

Globally, the numbers of weekly COVID-19 cases and deaths have continued to decline since late August (Figure 1). Over 2.8 million new cases and over 46 000 new deaths were reported during the week of 4 to 10 October 2021, representing decreases of 7% and 10% respectively, as compared to the previous week (Table 1). Apart from the European Region, which reported a 7% increase in the number of new weekly cases as compared to the previous week, all the other regions reported declines in new weekly cases. The largest decrease in new weekly cases was reported from the African Region (32%), followed by the Western Pacific Region (26%). The cumulative number of confirmed cases reported globally is now over 237 million and the cumulative number of deaths is over 4.8 million.

The number of new weekly deaths reported showed a large (>10%) decline for all regions except for the European Region, which reported an 11% increase as compared to the previous week. The largest decline in weekly deaths was reported from the Western Pacific and the African Regions, with both showing declines of 34% as compared to the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 10 October 2021**

**See [Annex 2: Data, table and figure notes](#)

The regions reporting the highest weekly case incidence rates per 100 000 population were the European Region (135.1 new cases per 100 000 population) and the Region of the Americas (92.8 new cases per 100 000 population), and the same two regions reported the highest weekly incidence in deaths, with both reporting 1.8 per 100 000 population.

The highest numbers of new cases were reported from the United States of America (653 837 new cases; 12% decrease), the United Kingdom (249 699 new cases; similar to the number reported in the previous week), Turkey (205 266 new cases; similar to the number reported in the previous week), the Russian Federation (188 829 new cases; 14% increase), and India (139 572 new cases; 13% decrease).

Globally, no new countries, territories or areas (hereafter countries) reported cases with VOCs in the past week. As of 12 October, cases of Alpha variant have been reported from 195 countries, Beta variant from 145 countries, Gamma variant from 99 countries, and Delta variant from 191 countries across all six WHO regions.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 10 October 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	949 371 (33%)	-13%	91 325 885 (38%)	18 565 (40%)	-14%	2 241 923 (46%)
Europe	1 260 455 (44%)	7%	71 863 813 (30%)	17 198 (37%)	11%	1 360 102 (28%)
South-East Asia	247 814 (9%)	-11%	43 369 716 (18%)	3 636 (8%)	-16%	681 671 (14%)
Eastern Mediterranean	144 710 (5%)	-13%	15 970 239 (7%)	3 002 (6%)	-16%	293 568 (6%)
Western Pacific	249 098 (9%)	-26%	8 858 812 (4%)	3 141 (7%)	-34%	120 846 (2%)
Africa	33 563 (1%)	-32%	6 081 759 (3%)	1 247 (3%)	-34%	148 101 (3%)
Global	2 885 011 (100%)	-7%	237 470 988 (100%)	46 789 (100%)	-10%	4 846 224 (100%)

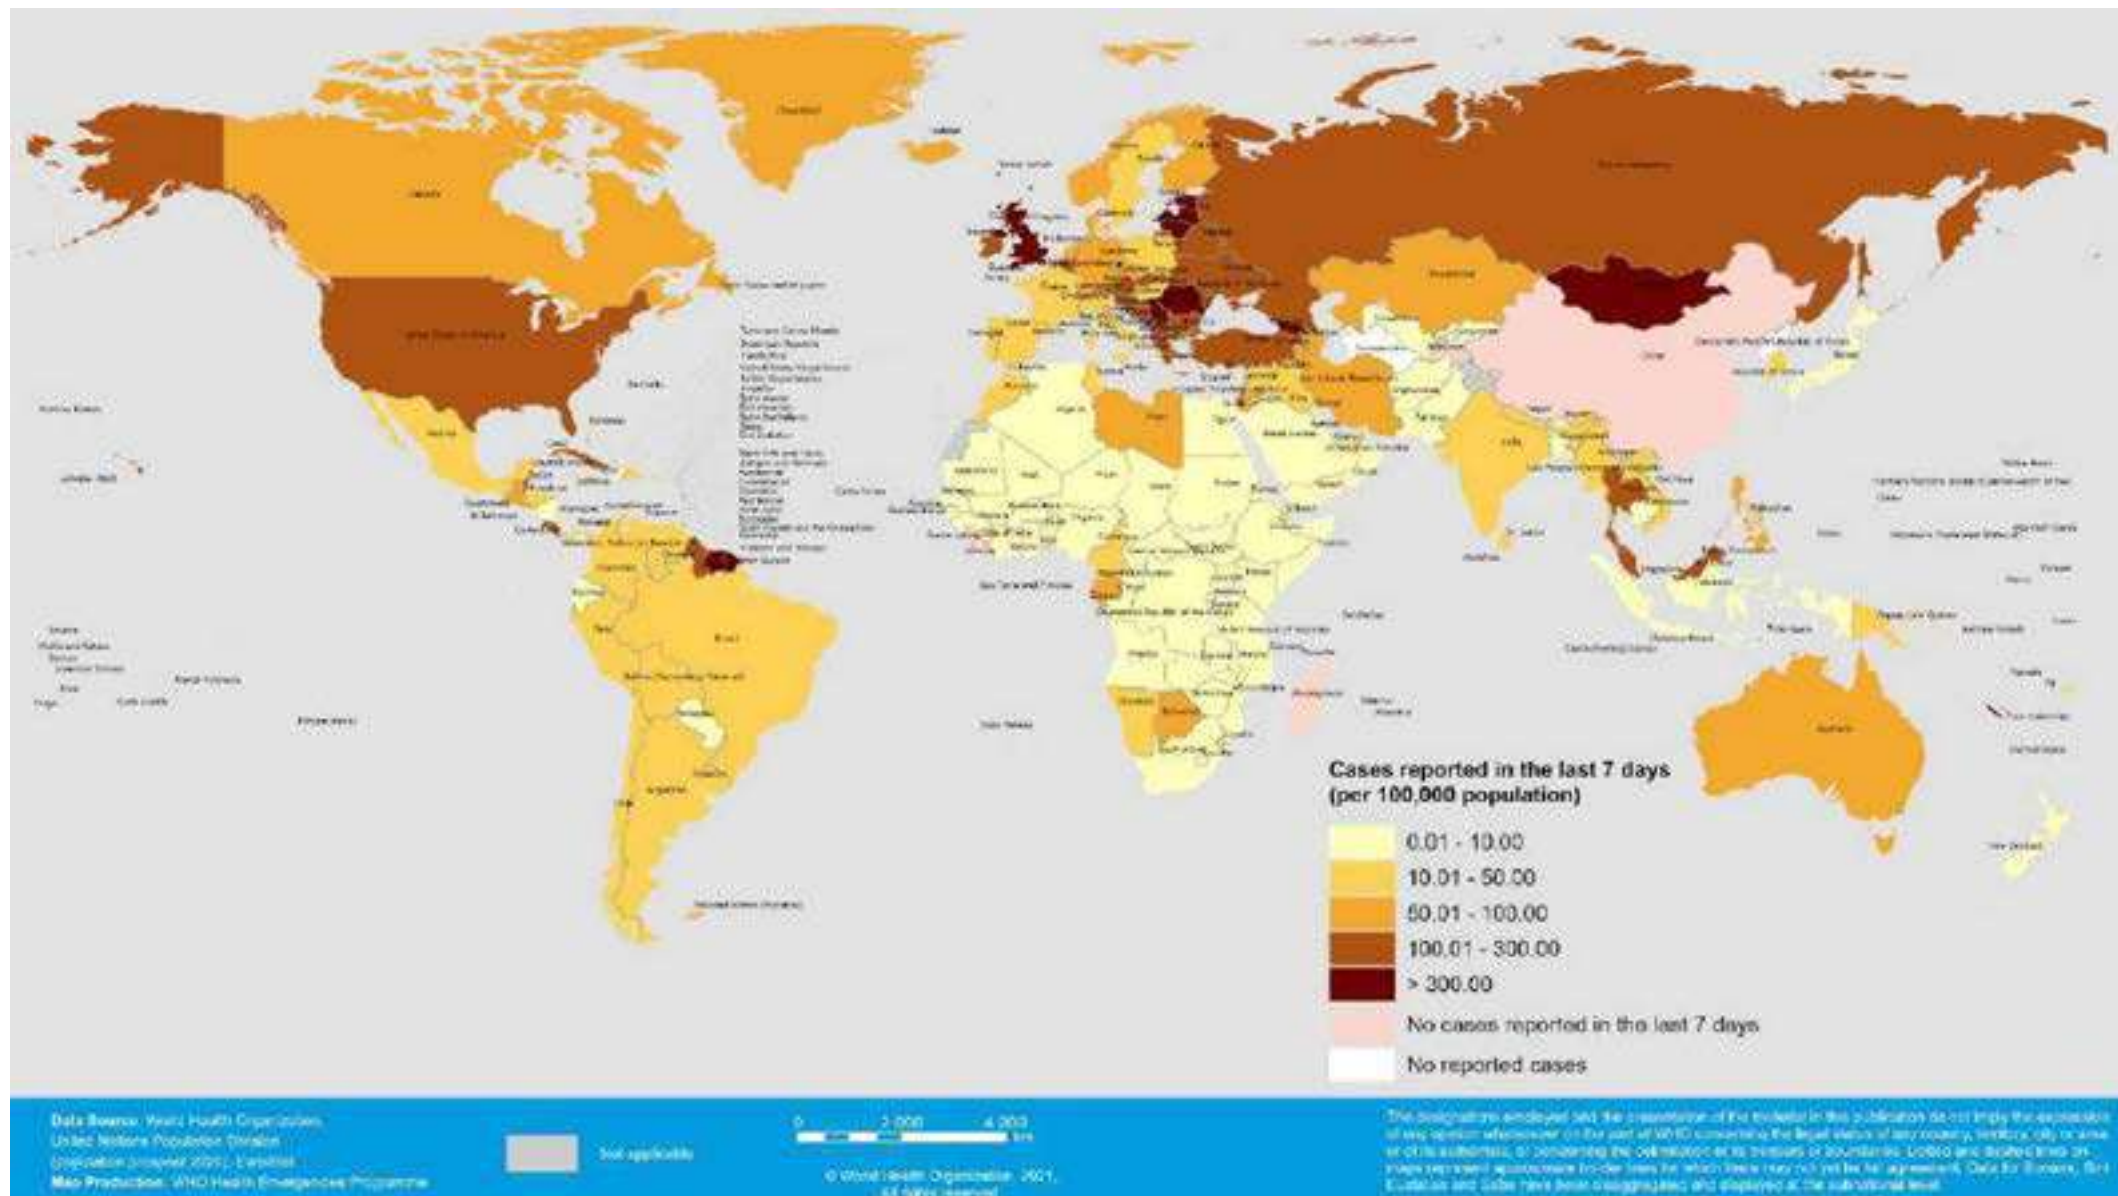

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As evidence becomes available, classification for VOIs or VOCs will be revised to reflect the continuous evolution of circulating variants and their changing epidemiology (see criteria for variant classification [here](#)). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

As these risks evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website). The prevalence of different variants is being monitored in light of other co-circulating variants, such as Delta.

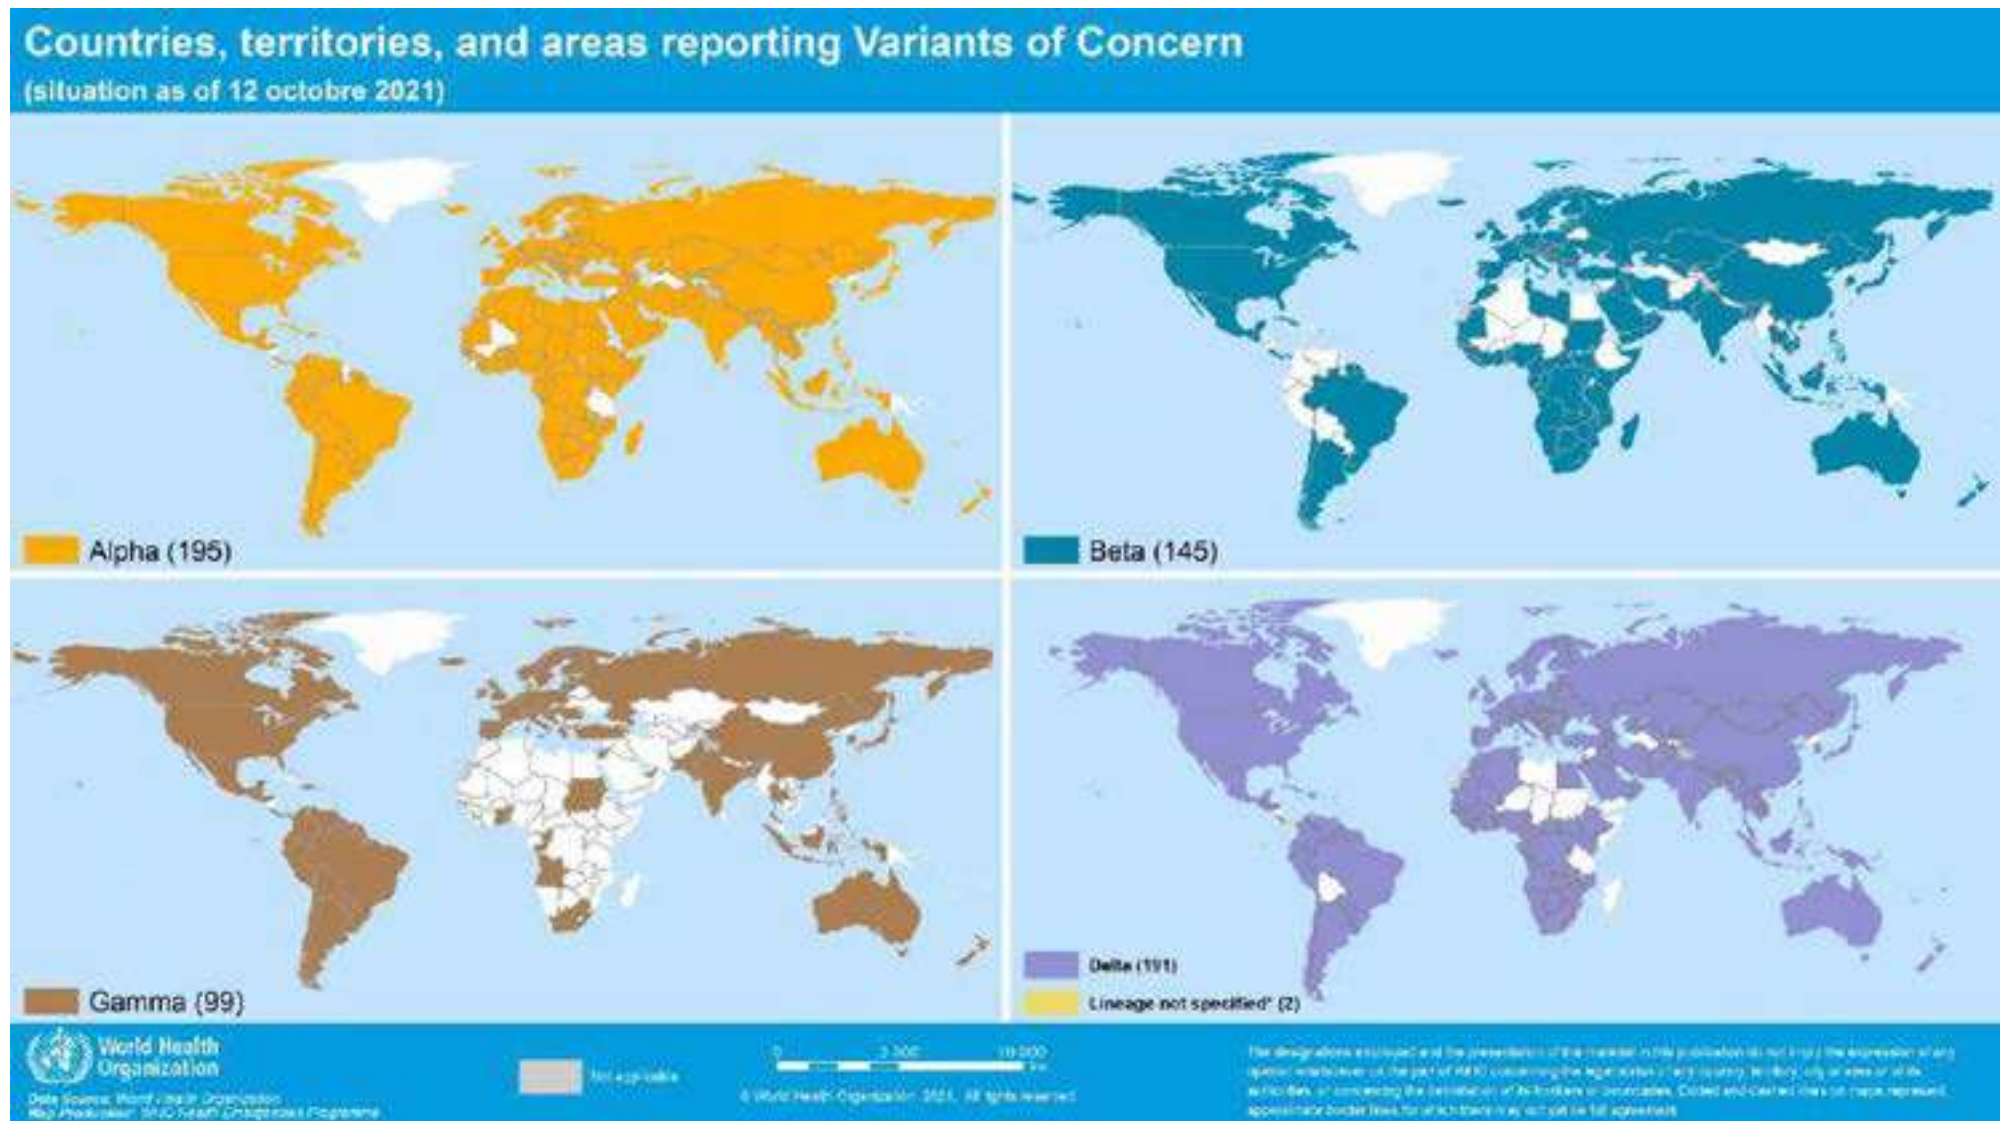

Globally, no new countries reported cases with VOCs in the past week (Figure 4, Annex 1). The current global epidemiology can be characterized by a predominance of the Delta variant, with declining prevalence of other VOCs among SARS-CoV-2 sequences reported to publicly available datasets. The global distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities, sampling strategies between countries and delays in reporting.

The inequitable access to vaccines increases the risk of emergence of new and even more threatening variants. As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on thorough risk assessments conducted systematically and routinely.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 12 October 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see Annex 2 for further details

WHO regional overviews Epidemiological week 4-10 October 2021

African Region

Since mid-July, the African Region has shown a constant decline in the number of COVID-19 cases and deaths, with over 33 000 new cases and over 1200 new deaths reported last week, a 32% and a 34% decrease respectively as compared to the previous week. While the majority of countries (35/49; 71%) reported a decrease in new weekly cases, seven countries reported an increase, with Chad (by 54%) reporting the greatest increase. The highest numbers of new cases were reported from Ethiopia (6061 new cases; 5.3 new cases per 100 000; a 15% decrease), South Africa (5884 new cases; 9.9 new cases per 100 000; a 39% decrease), and Cameroon (3096 new cases; 11.7 new cases per 100 000; a 55% decrease).

Concerning new weekly deaths, 75% of countries in the Region reported a decline whereas there was a marked increase observed in Senegal (by 125%) and Mali (by 100%). The highest numbers of new deaths were reported from South Africa (539 new deaths; <1 new death per 100 000; a 28% decrease), Ethiopia (275 new deaths; <1 new death per 100 000; a 10% decrease), and Cameroon (58 new deaths; <1 new death per 100 000; a 36% decrease).

Updates from the [African Region](#)

Region of the Americas

Since the end of August, the Region of the Americas has been reporting a declining trend in COVID-19 cases, with over 949 000 new cases reported this week, a 13% decrease as compared to previous week. Despite the declining trend in cases, 30% (17 out of 56 countries) reported an increase, with Montserrat (absolute numbers remain low), Saint Kitts and Nevis, and Saint Martin reporting the highest increase. The highest numbers of new cases were reported from the United States of America (653 837 new cases; 197.5 new cases per 100 000; a 12% decrease), Brazil (105 079 new cases; 49.4 new cases per 100 000; an 11% decrease), and Mexico (42 781 new cases; 33.2 new cases per 100 000; a 19% decrease).

For new weekly deaths, over 18 000 new deaths were reported this week, a 14% decrease compared to the previous week. The highest numbers of new deaths were reported from the United States of America (9080 new deaths; 2.7 new deaths per 100 000; a 21% decrease), Mexico (3632 new deaths; 2.8 new deaths per 100 000; an 11% increase), and Brazil (3200 new deaths; 1.5 new deaths per 100 000; a 10% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

During this week, the Eastern Mediterranean Region reported over 144 000 new cases and over 3000 new deaths, a 13% and a 16% decrease respectively as compared to the previous week; this follows the decline observed since mid- August 2021. While most of the countries (16/22; 73%) reported a decrease in new weekly cases, with the greatest decrease reported from Tunisia, Sudan and Somalia reported large increases in case incidence as compared to the previous week. The highest numbers of new cases were reported from the Islamic Republic of Iran (79 934 new cases; 95.2 new cases per 100 000; a 13% decrease), Iraq (14 882 new cases; 37.0 new cases per 100 000; similar figures as last week), and Pakistan (8986 new cases; 4.1 new cases per 100 000; a 21% decrease).

While most countries (14/22; 64%) in the Region reported a decline in new weekly deaths last week as compared to the previous week, Libya, Somalia and Sudan reported an increase. The highest numbers of new deaths were reported from the Islamic Republic of Iran (1490 new deaths; 1.8 new deaths per 100 000; an 18% decrease), Egypt (259 new deaths; <1 new death per 100 000; similar figures as last week), and Pakistan (256 new deaths; <1 new death per 100 000; a 17% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

Following a plateau in new weekly COVID-19 cases since mid-July, the Region reported a 7% increase compared to the previous week, with over 1.2 million new cases reported this week. Forty-six percent (28/61) of the countries showed an increase in the number of new weekly cases. The highest numbers of new cases were reported from the United Kingdom (249 699 new cases; 367.8 new cases per 100 000; similar to last week's figures), Turkey (205 266 new cases; 243.4 new cases per 100 000; similar to last week's figures), and the Russian Federation (188 829 new cases; 129.4 new cases per 100 000; a 14% increase).

During this week, over 17 000 new deaths have been reported in the Region, an 11% increase as compared to the previous week; continuing a steady increase observed since the end of June. Several countries in Eastern Europe including Czechia, Estonia, Hungary, Kyrgyzstan, Romania and Ukraine reported the greatest increase in new weekly deaths. Overall, the highest numbers of new deaths were reported from the Russian Federation (6497 new deaths; 4.5 new deaths per 100 000; an 8% increase), Romania (1854 new deaths; 9.6 new deaths per 100 000; a 54% increase), and Ukraine (1718 new deaths; 3.9 new deaths per 100 000; a 50% increase).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 247 000 new cases and over 3600 new deaths, an 11% and a 16% decrease, respectively as compared to the previous week. All countries reported a decrease in weekly new cases and weekly new deaths this week, with the greatest decrease reported from Timor-Leste. Overall, cases and deaths have continued to decline since early August. The highest numbers of new cases were reported from India (139 572 new cases; 10.1 new cases per 100 000; a 13% decrease), Thailand (73 452 new cases; 105.2 new cases per 100 000; similar to last week's figures), and Myanmar (10 188 new cases; 18.7 new cases per 100 000; similar to last week's figures).

The highest numbers of new deaths were reported from India (1772 new deaths; <1 new death per 100 000; a 7% decrease), Thailand (677 new deaths; <1 new deaths per 100 000; a 9% decrease), and Indonesia (478 new deaths; <1 new death per 100 000; a 32% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Since late August, COVID-19 cases have continued to show a declining trend in the region, with over 249 000 new cases, a 26% decrease as compared to the previous week. While most of the countries reported a decline in weekly cases this week, New Zealand, Papua New Guinea, Singapore and Australia reported an increase in cases as compared to the previous week. The highest numbers of new cases were reported from the Philippines (74 277 new cases; 67.8 new cases per 100 000; a 32% decrease), Malaysia (63 722 new cases; 196.9 new cases per 100 000; a 24% decrease), and Viet Nam (32 932 new cases; 33.8 new cases per 100 000; a 42% decrease).

Deaths continue to decline since early September, with over 3100 new deaths reported this week, a 34% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Philippines (849 new deaths; <1 new death per 100 000; a 32% decrease), Viet Nam (841 new deaths; <1 new death per 100 000; a 30% decrease), and Malaysia (700 new deaths; 2.2 new deaths per 100 000; a 50% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) (WOU) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework. In this week's edition, published on 13 October, highlights of country-level actions and WHO support to countries include:

- Scale-up to genomic sequencing capacities and monitoring of the evolution of SARS-CoV-2 in the African Region
- Supporting health workforce with personal protective equipment (PPE) in Yemen
- Support to national coordination through establishing Public Health Emergency Operations Centres in Armenia and Kyrgyzstan
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Roll-out of COVID-19 vaccine in Lao People's Democratic Republic
- Translating training tools to support frontline workers in Timor-Leste
- Issuing the SPRP mid-term report and updated appeal for urgent priorities and funding requirements
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

indicates that information for this variant was received by WHO from official sources.

indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community).

Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

-Kindly note that Delta has been discarded for Syrian Arab Republic upon verification.

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 60, published 5 October 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 3 October 2021

Globally, the numbers of weekly COVID-19 cases and deaths continued to decline. This is a trend that has been observed since August (Figure 1). Over 3.1 million new cases and just over 54 000 new deaths were reported during the week of 27 September to 3 October 2021. Cases this week decreased by 9% as compared to the previous week, while the number of deaths remained similar to that of the past week (Table 1). All regions reported a decline in the number of new cases this week apart from the European Region which reported a number similar to that of the previous week. The largest decrease in new weekly cases was reported from the African Region (43%), followed by the Eastern Mediterranean Region (21%), the South-East Asia Region (19%), the Region of the Americas (12%) and the Western Pacific (12%). The cumulative number of confirmed cases reported globally is now over 234 million and the cumulative number of deaths is just under 4.8 million.

The number of new weekly deaths reported showed a large (>10%) decline for all regions except for the Regions of the Americas and Europe, which both reported a similar number of weekly deaths as compared to previous week. The largest decline in weekly deaths was reported from the African Region, with a 25% decline as compared to the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 3 October 2021**

**See [Annex 2: Data, table and figure notes](#)

The regions reporting the highest weekly case incidence rates per 100 000 population were the European Region (123.1 new cases per 100 000 population) and the Region of the Americas (109.5 new cases per 100 000 population), while the same two regions reported this highest weekly incidence in deaths per 100 000 population; the Region of the Americas (2.4 new cases per 100 000 population) and the European Region (1.6 new cases per 100 000 population).

The highest numbers of new cases were reported from the United States of America (760 571 new cases; similar to the number reported in the previous week), the United Kingdom (239 781 new cases; similar to the number reported in the previous week), Turkey (197 277 new cases; similar to the number reported in the previous week), the Russian Federation (165 623 new cases; 13% increase), and India (161 158 new cases; 21% decrease).

Globally, cases of the Alpha variant have been reported in 195 countries, territories or areas (hereafter countries; two new countries added since last week), while 145 countries (3 new country since last week) have reported cases of the Beta variant; and 99 countries have reported cases of the Gamma variant (4 new countries since last week, with 1 report of the Gamma variant from last week being discarded upon sequencing). The Delta variant has been reported in 192 countries (seven new countries since last week: 2 under verification and 5 verified), across all six WHO regions as of 5 October.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 3 October 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 120 999 (36%)	-12%	90 357 809 (39%)	24 311 (45%)	2%	2 220 453 (46%)
Europe	1 164 750 (37%)	5%	70 589 709 (30%)	15 403 (28%)	2%	1 342 600 (28%)
South-East Asia	278 657 (9%)	-19%	43 121 902 (18%)	4 318 (8%)	-18%	678 035 (14%)
Eastern Mediterranean	166 068 (5%)	-21%	15 825 445 (7%)	3 567 (7%)	-17%	290 562 (6%)
Western Pacific	338 603 (11%)	-12%	8 609 714 (4%)	4 725 (9%)	-10%	117 705 (2%)
Africa	49 333 (2%)	-43%	6 048 196 (3%)	1 897 (3%)	-25%	146 854 (3%)
Global	3 118 410 (100%)	-9%	234 553 539 (100%)	54 221 (100%)	-4%	4 796 222 (100%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

Updates to the WHO SARS-CoV-2 variant tracking website

Given the continuous need to understand the epidemiological and clinical impacts of VOCs and VOIs, WHO regularly monitors and reviews circulation of variants. The changes in the rise of new variants are being monitored in light of other co-circulating variants, such as Delta.

This may mean that Variants of Interest (VOIs) or Variants of Concern (VOCs) may be outcompeted by newly emerging variants, such as VOC Delta. As evidence becomes available, we will revise classifications accordingly. These revisions reflect the continuous evolution of circulating variants and their changing epidemiology (see criteria for variant classification [here](#)).

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the strengthening of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Phenotypic characteristics

A recent peer-reviewed study evaluating persons infected with the Delta variant in France measured and compared the relative viral load with three other SARS-CoV-2 variants: Alpha, Beta and the non-VOC (20A.EU2) SARS-CoV-2 variant, collected from four hospital laboratories in the Paris area.¹ A total of 738 real time polymerase chain reaction (RT-PCR) SARS-CoV-2 positive nasopharyngeal samples collected from newly diagnosed COVID-19 cases, were screened to determine SARS-CoV-2 viral lineages and measure viral load. The results showed significant differences in the relative viral loads between Delta and other variants: viral loads of 2.5-fold higher were observed compared to Beta (median 7.26 [6.10–8.37]) ($p < 0.05$) and to the non-VOC variant; while infections with Alpha and Delta variants had similar viral loads.

A cross-sectional study (not yet peer reviewed), focusing on demographic characteristics, including severity of the illness and mortality rate, was conducted in India among COVID-19 cases caused by the non-VOC (B.1) variant and the Delta variant (B.1.617.2).² Using viral genomic sequences from 9500 COVID-19 patients, the study found an increased number of infections among younger age groups (0-19 years) and women, a lower mean age for infection and symptomatic illness/hospitalization, higher

mortality, and more frequent incidences of post-vaccination infections with Delta variant compared to the non-VOC (B.1) variant.

A retrospective cohort study conducted in the United States of America between 1 December 2020 and 30 July 2021 used sentinel surveillance to estimate the risk of hospitalization following infection with VOC or VOI, adjusting for age, sex, and vaccination status.³ Of the 27 814 cases identified, 23 170 (83.3%) samples were sequenced through sentinel surveillance, of which 726 (3.1%) were hospitalized due to COVID-19. A higher hospitalization risk was found for infections with Gamma (HR 3.17, 95% CI 2.15–4.67), Beta (HR: 2.97, 95% CI 1.65–5.35), Delta (HR: 2.30, 95% CI 1.69–3.15), and Alpha (HR 1.59, 95% CI 1.26–1.99) compared to infections with a non-VOC variant. Following infection with a VOC, unvaccinated patients showed a higher hospitalization risk when compared to patients with non-VOC infections. Additionally, vaccinated patients showed an overall lower risk of hospitalization when compared to unvaccinated patients although there was no increased risk in these groups when comparing VOC and non-VOC infections.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility ⁴	Increased transmissibility ^{5,6}	Increased transmissibility ^{6,7}	Increased transmissibility and secondary attack rate ^{6,8}
Disease severity	Increased risk of hospitalization ⁹ , possible increased risk of severity and mortality ^{10,11}	Not confirmed, possible increased risk of in-hospital mortality ¹²	possible increased risk of hospitalization ¹³ , risk of severity ¹⁴	Increased risk of hospitalization ^{15,16}
Risk of reinfection	Neutralizing activity retained ¹⁷ , risk of reinfection remains similar ¹⁸	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ¹⁹	Moderate reduction in neutralizing activity reported ²⁰	Reduction in neutralizing activity reported ^{21–23}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF); no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed ²⁴	No impact on RT-PCR or Ag RDTs observed ²³	None reported to date	None reported to date

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

VE refers to vaccine effectiveness and vaccine efficacy

⁺As of submission of this update

*Summary of VE: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization.

reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used.

“Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the VIEW-hub Resources page (<https://view-hub.org/resources>). For individual vaccine effectiveness studies, see ‘COVID-19 Vaccine Effectiveness Results Summary’, reference numbers noted with a ‘#’. For a list of all neutralization studies, see ‘COVID-19 Vaccine Neutralization Studies Table’.

References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table and are included in the reference section below.

Additional notes on VOC impacts on vaccines

- Studies reporting VOC-specific vaccine efficacy or effectiveness (VE) estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates for these outcomes, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Table 3 summarizes the impact of VOCs on COVID-19 vaccine performance in the absence of waning, and, therefore, does not include studies that only assess VE greater than four months post final dose.

Table 3 presents the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to VE in non-VOC settings. Of note, reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of approximately 85%. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection overall, as is the case for the AstraZeneca-Vaxzevria vaccine.

Since the [21 September update](#), six notable new studies have provided evidence of COVID-19 vaccine performance after full vaccination against VOCs.

A pre-print study from the United Kingdom provided VOC-specific estimates of the effectiveness of COVID-19 vaccines. This study found that Pfizer BioNTech-Comirnaty provided similar levels of protection against infection due to Alpha (VE: 94%, 95% CI: 90-96%) and Delta (VE: 90%, 95%CI: 87-92%) 14 or more days post second dose, among household contacts of confirmed cases, with follow-up time since full vaccination up to ~20.5 weeks for Alpha cases and ~29 weeks for Delta cases.³² AstraZeneca-Vaxzevria also had similar levels of protection against infection due to Alpha and Delta, with VE estimates of 71% (51-83%) and 72% (68-75%), respectively, with follow-up time since full vaccination up to ~8 weeks for Alpha cases and ~16 weeks for Delta cases.

A second study, not yet peer reviewed, evaluated the performance of Moderna-mRNA-1273 in the United States of America among persons who were included in a phase III randomized clinical trial of the vaccine, after study participants had been unblinded and persons in the placebo group were offered vaccination.³³ During the period from July to August 2021 (when Delta accounted for 97% of all cases sequenced), persons initially randomized to the vaccine arm and vaccinated between July and December 2020 experienced a higher incidence rate (IR) of symptomatic disease and severe disease (symptomatic disease IR: 77.1/1000 person-years; severe disease IR: 6.2/1000 person years) compared to persons initially assigned to the placebo group but vaccinated more recently between December 2020 and April 2021 (symptomatic disease

IR: 49.0/1000 person-years; severe disease IR: 3.3/1000 person years). This finding is suggestive of waning vaccine efficacy, although it was not possible to calculate an efficacy estimate using this case-only approach.

Two additional studies assessed performance of COVID-19 vaccines in outbreak settings. The first pre-print study evaluated the effectiveness of Pfizer BioNTech-Comirnaty in preventing infection and disease among residents and staff of a nursing home in Germany during an outbreak of the Alpha variant.³⁴ Two doses of the vaccine was 45% (0-69%), 68% (36-84%), and 88% (37-98%) effective at preventing infection, symptomatic disease, and hospitalization due to Alpha, respectively, seven or more days post second dose. The maximum follow-up after full vaccination was ~11 weeks. Authors also found that cycle threshold values at the time of SARS-CoV-2 detection were higher (suggesting lower viral load) among cases vaccinated more than 21 days prior compared to those vaccinated within 21 days of SARS-CoV-2 detection. Furthermore, the secondary attack rate was lower among household contacts of vaccinated cases (22.2%) than among household contacts of unvaccinated cases (66.7%). Another investigation of an outbreak of Delta in a prison in the USA found higher attack rates among unvaccinated (93%) persons as compared to those who had been vaccinated with Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273, or Janssen-Ad26.COV 2.5, combined (70%).³⁵ In addition, higher attack rates were observed among persons vaccinated ≥ 4 months prior to the outbreak (89%) compared to those vaccinated within two weeks to two months prior to the outbreak (61%). Among those vaccinated, 66% had received Pfizer BioNTech-Comirnaty, 27% had received Moderna-mRNA-1273, and 7% had received Janssen-Ad26.COV 2.5; all persons vaccinated ≥ 4 months prior to the outbreak had received Pfizer BioNTech-Comirnaty.

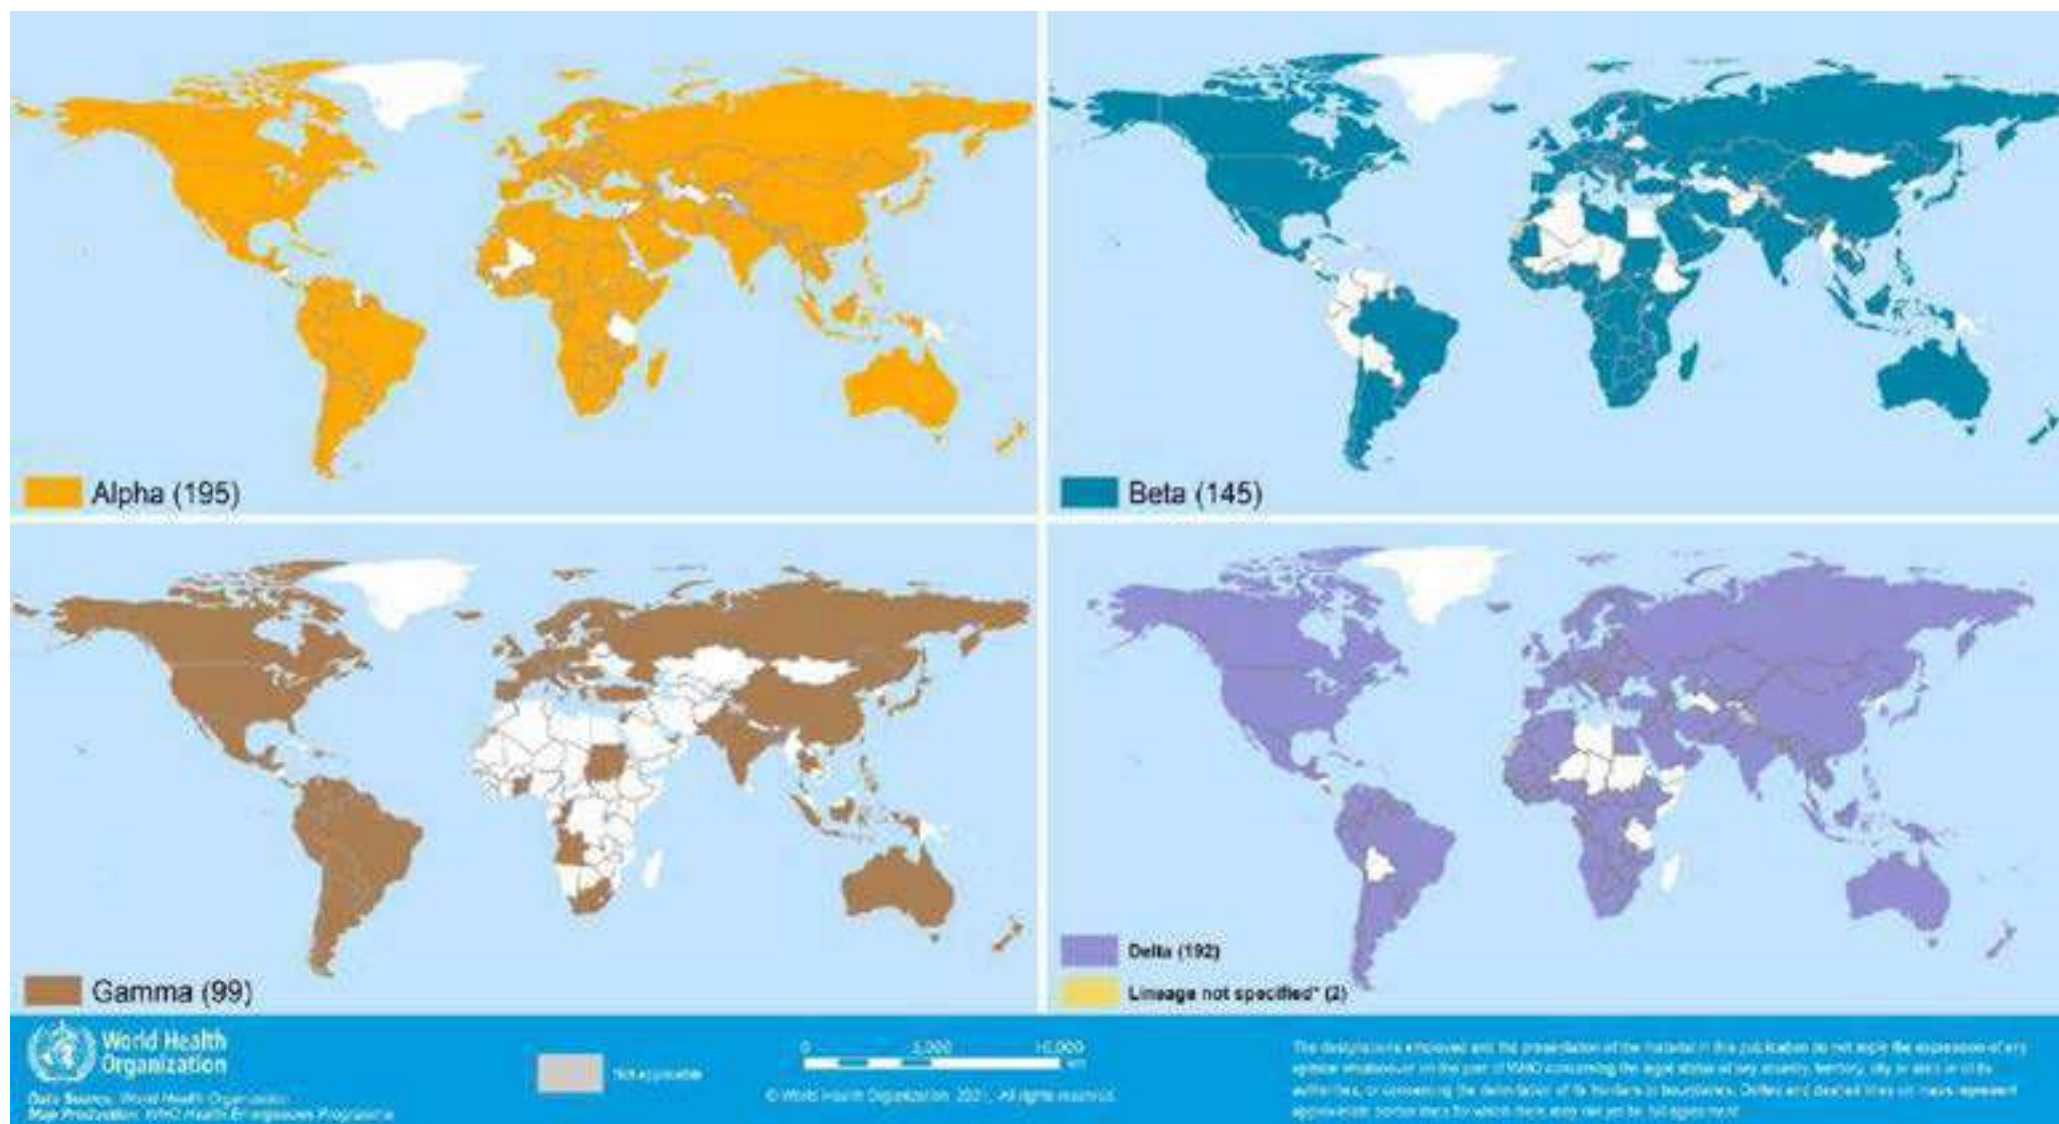

Finally, two retrospective cohort studies from Israel provide further data on the effectiveness of the Pfizer BioNTech-Comirnaty vaccine. The first, a peer-reviewed study, conducted during a period of high Alpha prevalence, found that the vaccine was over 95% effective for each at preventing infection, symptomatic disease, hospitalization, and death 22-28 days post receipt of the second dose among persons 16 years and older.³⁶ The second study, a pre-print, conducted during a time of high Delta prevalence, found Pfizer BioNTech-Comirnaty to be 91.5% (88.2-93.9%) effective against SARS-CoV-2 infection 8-28 days post second dose in children 12-15 years of age.³⁷

Together these studies provide further evidence of high effectiveness of the mRNA vaccines and AstraZeneca-Vaxzevria vaccine against SARS-CoV-2 infection, and symptomatic and severe COVID-19 disease due to Alpha and Delta variants, although there remains some indication of decreasing effectiveness against infection and symptomatic disease as time since complete vaccination.

Figure 5. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 5 October 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see Annex 2 for further details

WHO regional overviews Epidemiological week 27 September-3 October 2021

African Region

The African Region reported over 49 000 new cases and just under 1900 new deaths, decreases of 43% and 25% respectively as compared to the previous week. The declining trend in cases reported in the region and observed since early July continued this week. While this trend is true for most countries in the region, in the past week, seven countries reported increases of over 20% in new cases as compared to the previous week.

The highest numbers of new cases were reported from South Africa (9637 new cases; 16.2 new cases per 100 000 population; a 38% decrease), Ethiopia (7127 new cases; 6.2 new cases per 100 000; a 19% decrease), and Lesotho* (6943 new cases; 324.1 new cases per 100 000). The highest numbers of new deaths were reported from South Africa (752 new deaths; 1.3 new deaths per 100 000 population; a 15% decrease), Ethiopia (306 new deaths; <1 new death per 100 000; a 20% increase), and Lesotho* (231 new deaths; 10.8 new deaths per 100 000).

Updates from the [African Region](#)

* This marked increase was reported by Lesotho on 30 September 2021 as a batch number for both cases and deaths and will be reviewed as more information becomes available.

Region of the Americas

The Region of the Americas reported over 1.1 million new cases, a 12% decrease as compared to the previous week, and just over 24 000 new deaths, which was similar to the number reported the previous week. Overall, while the region has been reporting declining trends in both cases and deaths over the past month, the weekly incidence remains at levels below the peak seen in March.

The highest numbers of new cases were reported from the United States of America (760 571 new cases; 229.8 new cases per 100 000; similar to last week), Brazil (131 501 new cases; 61.9 new cases per 100 000; a 47% decrease), and Mexico (52 496 new cases; 40.7 new cases per 100 000; a 21% decrease). The highest numbers of new deaths were reported from the United States of America (13 736 new deaths; 4.1 new deaths per 100 000; a 12% increase), Brazil (4060 new deaths; 1.9 new deaths per 100 000; similar to last week), and Mexico (3275 new deaths; 2.5 new deaths per 100 000; a 21% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

Since a peak in incidence in both cases and deaths in early August this year, weekly cases and deaths have continued to consistently decline in the Eastern Mediterranean Region. This week, the region reported over 166 000 new cases and over 3500 new deaths, decreases of 21% and 17% respectively as compared to the previous week. The highest numbers of new cases were reported from the Islamic Republic of Iran (91 972 new cases; 109.5 new cases per 100 000; a 17% decrease), Iraq (15 599 new cases; 38.8 new cases per 100 000; an 18% decrease), and Pakistan (11 314 new cases; 5.1 new cases per 100 000; a 28% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1808 new deaths; 2.2 new deaths per 100 000; a 21% decrease), Pakistan (307 new deaths; <1 new death per 100 000; a 21% decrease), and Iraq (272 new deaths; <1 new death per 100 000; an 8% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 1.1 million new cases and over 15 000 new deaths, with both numbers similar to the numbers reported in the previous week. Following sharp declines in the incidence in both cases and deaths between March and June this year, numbers in the European Region spiked again in July and have since remained at higher but more stable levels ($\leq 5\%$ change) for the past three months. The highest numbers of new cases were reported from the United Kingdom (239 781 new cases; 353.2 new cases per 100 000; similar to previous week), Turkey (197 277 new cases; 233.9 new cases per 100 000; a number similar to that of the previous week), and the Russian Federation (165 623 new cases; 113.5 new cases per 100 000; a 13% increase).

The highest numbers of new deaths were reported from the Russian Federation (6018 new deaths; 4.1 new deaths per 100 000; a 6% increase), Turkey (1529 new deaths; 1.8 new deaths per 100 000; a number similar to that of previous week), and Ukraine (1149 new deaths; 2.6 new deaths per 100 000; a 53% increase).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 278 000 new cases and over 4300 new deaths, decreases of 19% and 18% respectively as compared to the previous week. This sustained regional decline in both cases and deaths has been observed since late July. This week, only one country- Bhutan - reported an increase in cases - although absolute numbers reported remain low. Similarly, Nepal was the only country to report an increase in the number of new deaths this week (68 new deaths; a 21% increase). The highest numbers of new cases were reported from India (161 158 new cases; 11.7 new cases per 100 000; a 21% decrease), Thailand (75 794 new cases; 108.6 new cases per 100 000; an 11% decrease), and Indonesia (11 271 new cases; 4.1 new cases per 100 000; a 35% decrease).

The highest numbers of new deaths were reported from India (1899 new deaths; <1 new death per 100 000; a 9% decrease), Thailand (746 new deaths; 1.1 new deaths per 100 000; an 18% decrease), and Indonesia (706 new deaths; <1 new death per 100 000; a 29% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 338 000 new cases and over 4700 new deaths, decreases of 12% and 10% respectively as compared to the previous week. After a sustained period of relatively stable numbers of both weekly cases and deaths, both began to rapidly increase from late June this year. However, this has been followed by consistent decreases in new cases and deaths observed in the region for over a month now and this is largely driven by declines in the Philippines and Malaysia. The highest numbers of new cases were reported from the Philippines (110 023 new cases; 100.4 new cases per 100 000; a 10% decrease), Malaysia (83 368 new cases; 257.6 new cases per 100 000; an 18% decrease), and Viet Nam (56 524 new cases; 58.1 new cases per 100 000; a 19% decrease).

The highest numbers of new deaths were reported from Malaysia (1406 new deaths; 4.3 new deaths per 100 000; a 33% decrease), the Philippines (1251 new deaths; 1.1 new deaths per 100 000; a 52% increase), and Viet Nam (1201 new deaths; 1.2 new deaths per 100 000; a 22% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) (WOU) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this week's edition of the COVID-19 Weekly Operational Update, published on 4 October, highlights of country-level actions and WHO support to countries include:

- Nearly a third of African countries hit 10% COVID-19 vaccination goal: support to accelerate vaccine rollouts
- Supporting national vaccine cold chain system in Islamic Republic of Iran
- WHO/Europe supports COVID-19 intensive care in Georgia
- Fourth Intra-Action Review (IAR) Meeting to strengthen Indonesia's COVID-19 response
- Working together in Nicaragua to bring training to the front lines
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

For more information, see the [Weekly operational update on COVID-19](#)

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

indicates that information for this variant was received by WHO from official sources.

indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 59, published 28 September 2021

In this edition:

- [Global overview](#)
- [Special focus: Approaches to determining waning COVID-19 vaccine effectiveness](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 26 September 2021

Globally, the numbers of weekly COVID-19 cases and deaths continued to decline (Figure 1). Over 3.3 million new cases and over 55 000 new deaths were reported during the week of 20 – 26 September 2021, decreases of 10% as compared to the previous week for both cases and deaths (Table 1). The largest decrease in new weekly cases was reported from the Eastern Mediterranean Region (17%), followed by the Western Pacific Region (15%), the Region of the Americas (14%), the African Region (12%) and the South-East Asia Region (10%); while weekly cases in the European Region were similar to the previous week. The cumulative number of confirmed cases reported globally is now over 231 million and the cumulative number of deaths is more than 4.7 million.

The number of new weekly deaths reported showed a large (>15%) decline for all regions except for the European Region, which reported a similar number of weekly deaths compared to previous week, and the African Region which reported a slight increase (5%). The largest decline in weekly deaths was reported from the Western Pacific Region, with a 24% decline as compared to the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 26 September 2021**

****See [Annex 2: Data, table and figure notes](#)**

The regions reporting the highest weekly case and death incidence rates per 100 000 population remain the same as in the previous weeks: the Region of the Americas (124.6 new cases per 100 000 population; 2.3 deaths per 100 000 population) and the European Region (117.6 new cases per 100 000 population; 1.6 deaths per 100 000 population).

The highest numbers of new cases were reported from the United States of America (765 827 new cases; 31% decrease), Brazil (247 397 new cases; 135% increase due to changes in reporting), the United Kingdom (230 494 new cases; 14% increase), India (204 582 new cases; similar to previous week), and Turkey (192 778 new cases; similar to previous week), while the highest numbers of new deaths were from the United States of America (14 842 new deaths, a 17% decrease), the Russian Federation (5469 new deaths, similar to the previous week), Mexico (3689 new deaths, a 13% increase), Brazil (3727 new deaths, a 10% increase), and the Islamic Republic of Iran (2967 new deaths, a 23% decrease) respectively.

Globally, cases of the Alpha variant have been reported in 193 countries, territories or areas (hereafter countries; no new country added since last two weeks), while 142 countries (no new country since last week) have reported cases of the Beta variant; and 96 countries (no new countries since last week) have reported cases of the Gamma variant. The Delta variant has been reported in 187 countries (two new countries since last week), across all six WHO regions as of 28 September.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 26 September 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 273 971 (38%)	-14%	89 236 517 (39%)	23 890 (43%)	-10%	2 196 144 (46%)
Europe	1 097 735 (32%)	-1%	69 411 718 (30%)	14 638 (26%)	-1%	1 326 559 (28%)
South-East Asia	344 305 (10%)	-10%	42 843 227 (19%)	5 249 (9%)	-20%	673 717 (14%)
Eastern Mediterranean	209 329 (6%)	-17%	15 659 306 (7%)	4 284 (8%)	-16%	286 995 (6%)
Western Pacific	378 919 (11%)	-15%	8 266 265 (4%)	5 233 (9%)	-24%	112 945 (2%)
Africa	87 135 (3%)	-12%	5 998 863 (3%)	2 536 (5%)	5%	144 957 (3%)
Global	3 391 394 (100%)	-10%	231 416 660 (100%)	55 830 (100%)	-10%	4 741 330 (100%)

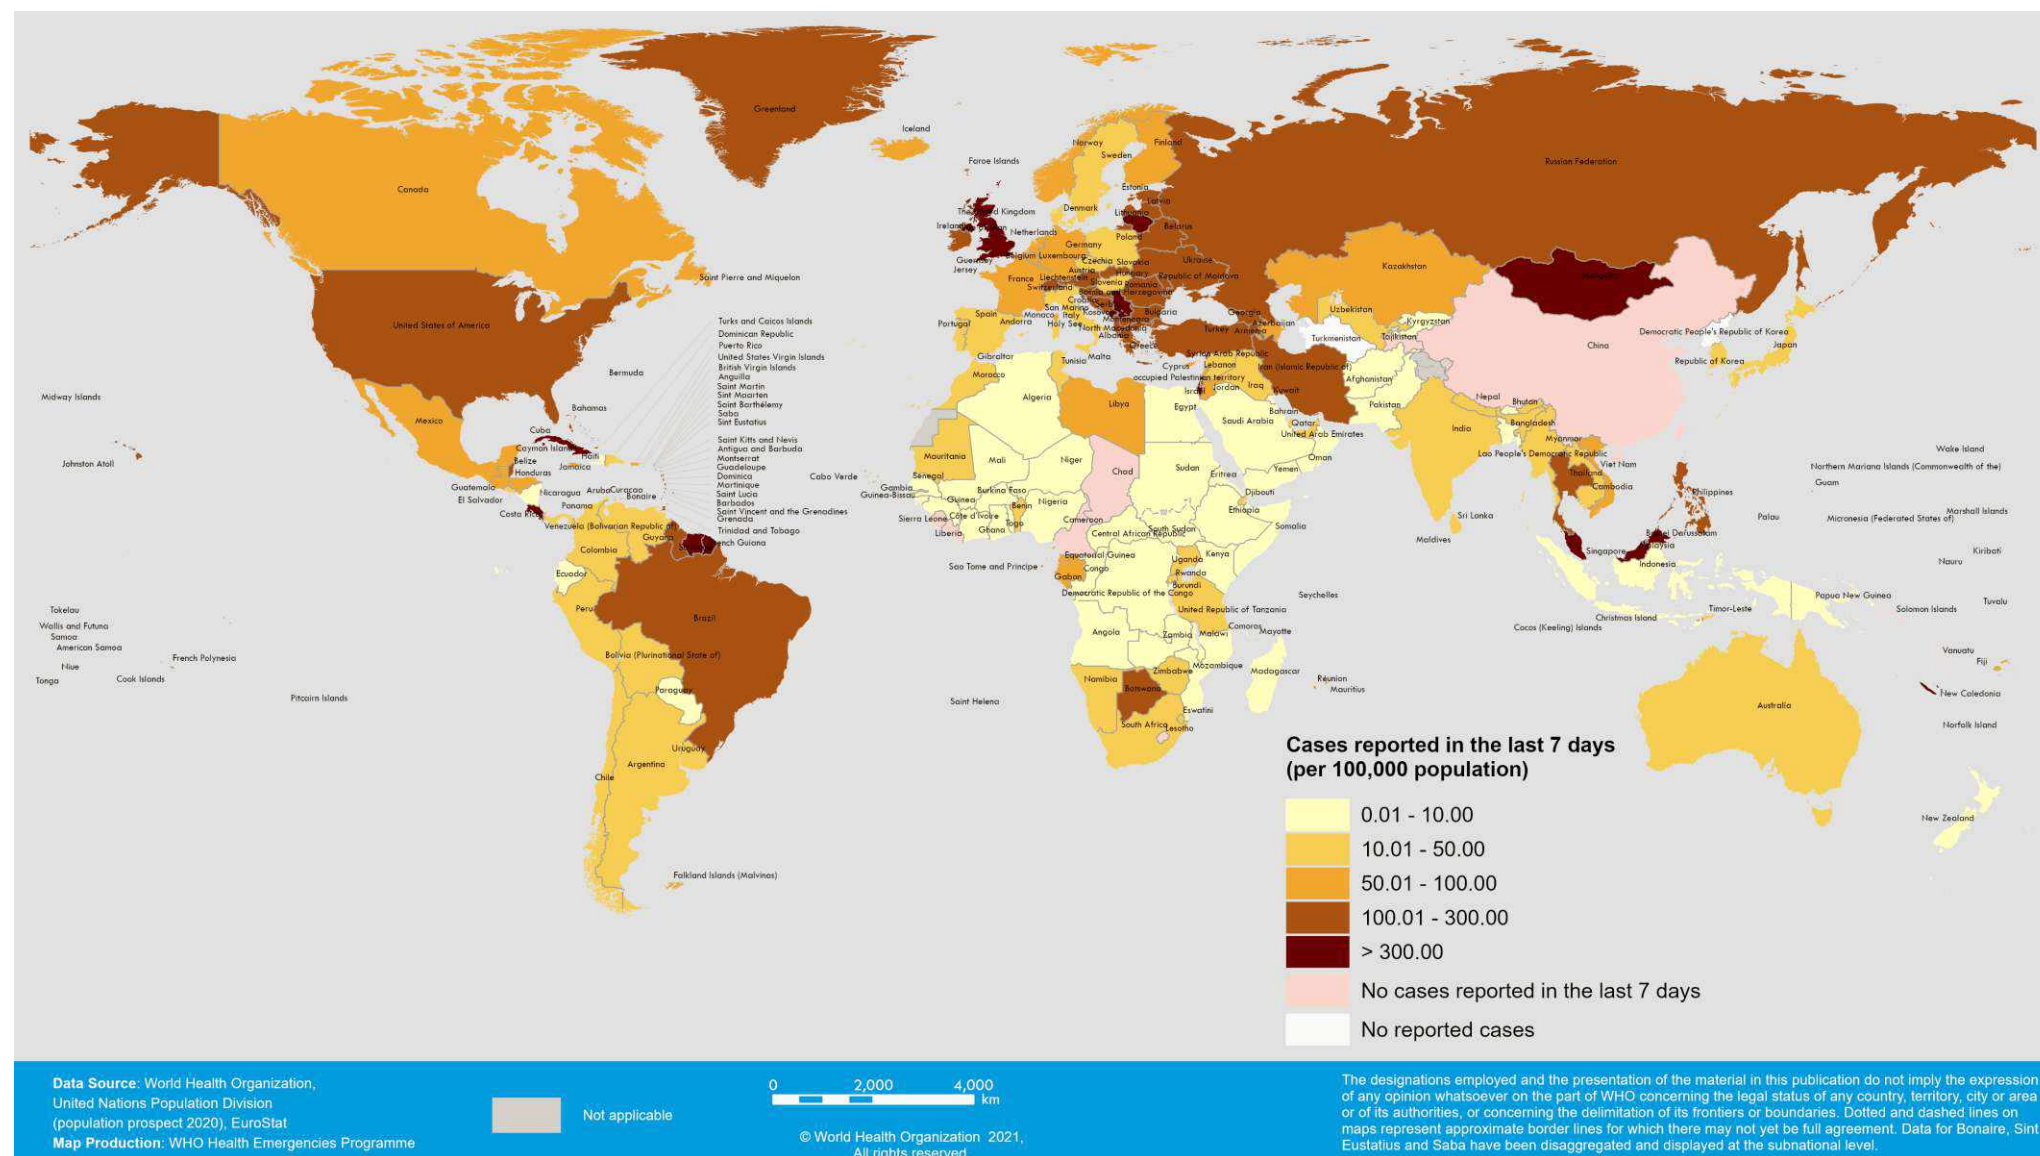

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

Special Focus: Approaches to determining waning COVID-19 vaccine effectiveness

Why should we be concerned about waning immunity?

More than 21 months into the pandemic, there remains critical information that remains unknown about SARS-CoV-2 and the disease it causes: COVID-19. One of these topics is whether immunity conferred after vaccination or infection wanes over time. Knowing whether and to what extent immunity may wane in the mid- to long-term is critical to inform the public health response and policy decisions. Here, we focus on waning immunity following vaccination – we describe the different ways in which scientists have studied changes in vaccine effectiveness in people who have been vaccinated over time and provide a summary of the findings thus far.

Does immunity wane after vaccination?

Multiple COVID-19 vaccines have received [Emergency Use Listing \(EUL\)](#) from WHO based on vaccine efficacy results from randomized controlled clinical trials¹. However, the follow-up time of the clinical trials used to assess vaccine efficacy for EUL was shorter than the usual follow-up time for trials of other new vaccines, with most efficacy results having a median follow-up time of two months. Outside clinical trial settings, vaccine effectiveness (VE) results among persons immunized as part of national vaccine roll-outs were similar to the findings of the clinical trials in the first few months after vaccines began to be administered². However, despite the encouraging results of early VE studies, the duration of reported protection for COVID-19 vaccines require continued monitoring because in vitro studies of neutralization by vaccine-induced antibodies showed that, levels of most vaccine-derived antibodies declined over time (for more details, please see Special Focus published in [Weekly Epidemiological Update on 27 July](#))³. However, it is important to consider that the antibody response is only one part of the immune response. It is not known what level of antibodies in the body is needed to provide protection against SARS-CoV-2 infection or severe disease, nor whether vaccine-derived memory cells will be activated in response to subsequent exposure to SARS-CoV-2, nor whether any observed decline in antibodies correspond to decreases in VE and if so, over what timeframe⁴.

Approaches to assess waning vaccine effectiveness against infection and all symptomatic disease

Interval-based estimates

Most VE studies provide estimates of cumulative VE to represent VE from 7-14 days after full vaccination through a defined follow-up period, the duration of which varies by study⁵. However, cumulative VE estimates can obscure any waning VE during the latter part of the follow-up period, particularly in situations when most cases occur in the months soon after vaccination. Several approaches have been taken to address this limitation, the most common being to measure the VE at fixed intervals after vaccination. As of 21 September 2021, an interval-based assessment of efficacy from one randomized controlled trial⁶ and VE from eight real-world studies have identified waning VE for infection and symptomatic disease in several settings, for four COVID-19 vaccines⁷⁻¹⁴ (Figure 4). Vaccine effectiveness appears to peak 1-2 months after vaccination and then starts to decline from the third month after vaccination for Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines in some studies^{6-8,12-13}. Only one study has assessed VE at different time intervals up to 3.5 months post-vaccination for the Moderna-mRNA-1273 vaccine and, unlike the studies mentioned above, did not show any apparent waning against symptomatic infection⁷.

A potential problem with the interval-based approach to VE estimates is that circulation of a new variant with more pronounced immune escape characteristics, such as the Beta or Delta variants, during the follow-up period can confound the later VE estimates. Limiting the analysis to only cases caused by a single variant over time can disaggregate waning VE from reduced VE due to a specific variant. To address this potential confounding factor, a study from the United Kingdom, using a test-negative design, demonstrated waning VE against symptomatic disease caused by the Delta variant for both the Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines from 10 weeks after full vaccination⁷. A study conducted in Qatar, found

waning VE against infection with Alpha, Beta and Delta variants three to four months after complete vaccination with Pfizer BioNTech-Comirnaty; however, confidence intervals for some time periods were wide and overlapping⁸. Most VE studies do not conduct genomic characterization for all cases as the studies in the United Kingdom and Qatar did, which limits the ability to differentiate waning VE from reduced VE due to variants.

Case-only analysis of vaccinated cases

Another approach to the interval-based approach is to undertake a case-only analysis of vaccinated cases, comparing rates of breakthrough infections and disease during a defined time period, stratified by the time of vaccination. A recent study from Israel measured incidence during a 3-week period in July 2021 when the Delta variant was the predominant variant, stratified by the month of vaccination¹². It found rates of SARS-CoV-2 infection in July 2021 were two-fold or higher for those vaccinated in late January 2021 compared to May 2021. A case-only approach does not yield a VE estimate, which requires a comparison to unvaccinated persons, so this study did not provide estimates of waning VE.

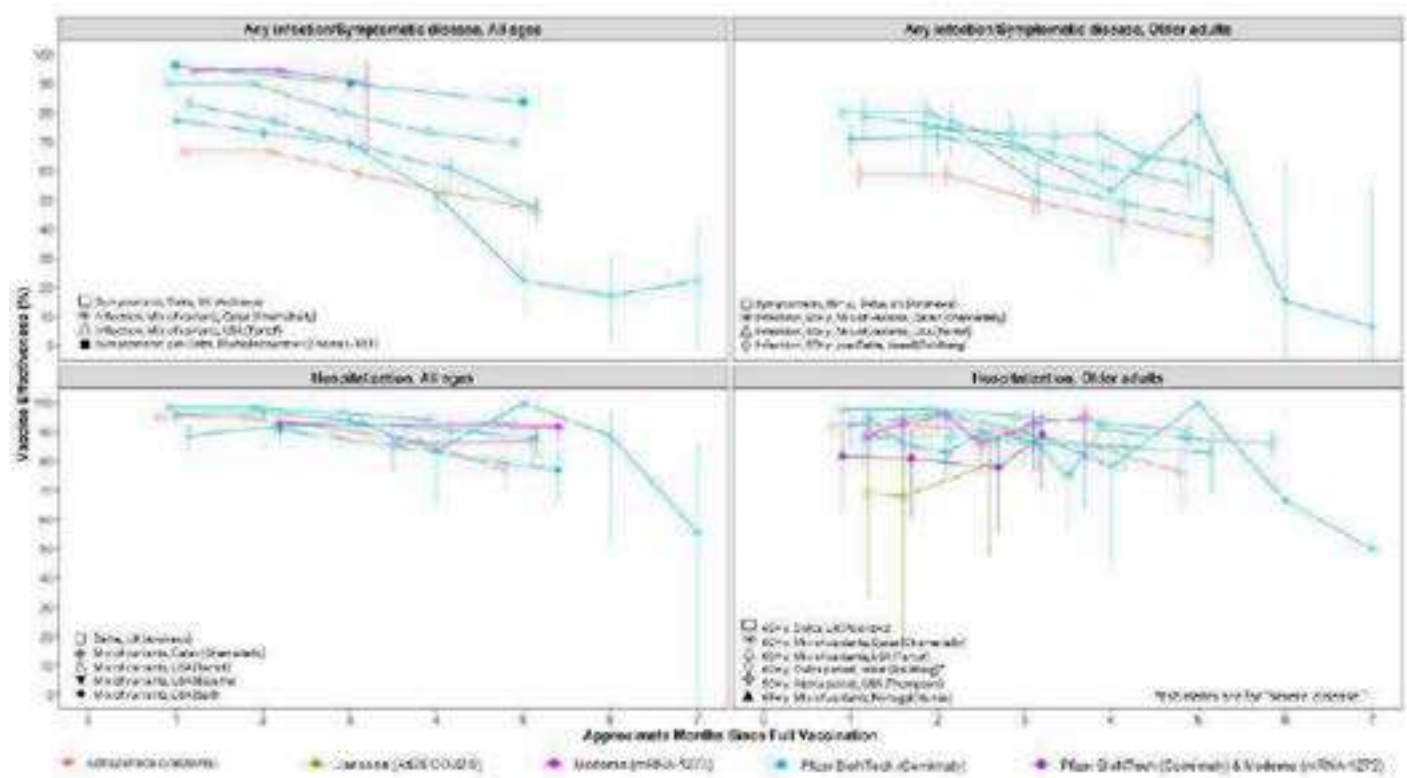

Comparison of disease occurrence

Another methodology to assess waning VE is using rates of breakthrough cases to compare the incidence rate ratio (IRR) between vaccinated and unvaccinated persons at different time points. This approach was used in 13 jurisdictions the United States of America where the age-standardized IRR for all COVID-19 symptomatic disease between those not fully vaccinated and those who were fully vaccinated decreased from 11.1 (95% CI, 7.8-15.8) between 5 April – 19 June 2021, to 4.6 (95% CI, 2.5-8.5) between 20 June - 17 July 2021¹⁵. A limitation of this study was the inability to disaggregate the effect of waning due to time since vaccination versus the increased circulation of the Delta variant in the later time period. An additional limitation was the challenge of accounting for confounding.

Approaches to assess waning immunity against hospitalization and severe disease

These same approaches described above have also been used to assess waning VE against hospitalization/severe disease. In contrast to the findings for infection and symptomatic disease, the VE against severe outcomes remains high ($\geq 75\%$) over time for Pfizer BioNTech-Comirnaty, AstraZeneca-Vaxzevria, Moderna-mRNA-1273, and $\geq 68\%$ for Janssen-Ad26.COV2.S. (Figure 1)^{9, 10, 11, 14}. However, some studies, done in settings where the Delta variant was predominant, have shown that VE against severe disease dropped by 5-15 percentage points from four months after vaccination with Pfizer BioNTech-Comirnaty in Israel, the United Kingdom, Qatar and the United States of America^{7, 8, 12, 13}, and AstraZeneca-Vaxzevria in the United Kingdom⁷. No waning was seen for Moderna-mRNA-1273, and Janssen-Ad26.COV2.S, although there was less follow-up time for these vaccines. Further follow-up of the VE against severe disease for all vaccines is needed to clarify if and how much waning VE might occur after more time has elapsed since full vaccination.

Figure 4: Vaccine effectiveness against infection and symptomatic disease and hospitalization for all ages and older adults⁶⁻¹⁴

What type of biases must be considered?

There are multiple sources of bias that are present in observational studies of VE and that need to be considered by researchers who design and conduct the studies, as well as media professionals and the public when interpreting the study results. While none of these biases invalidate findings from observational studies which assess VE, we should pay close attention to them to understand results from studies. These potential biases include:

- Individuals prioritized for vaccination early in vaccination campaigns were often those at higher risk for SARS-CoV-2 infection and/or severe COVID-19, such as frontline workers, older people and long-term care facility residents. These people may continue to be at higher risk of exposure, infection, and/or severe disease over time and they will be over-represented among individuals with the longest follow-up time after vaccination, resulting in apparent waning VE.
- Those who have been vaccinated may change their behavior, engaging in activities that may increase their exposure to the virus as they gain a sense of increased protection.
- Those who have been vaccinated may differ from those who remain unvaccinated with respect to their propensity to get tested for COVID-19 over time. The use of a test-negative study design partially addresses this potential bias¹⁶ through accounting, in part, for health seeking behaviours.
- As more time elapses since vaccination, it is possible that there may be more misclassification of vaccine status, whereby vaccination status is not documented for some people, falsely assigning them to the unvaccinated group, even though they may indeed have vaccine-derived protection.
- The cause of death may be misclassified as being COVID-19, particularly in elderly individuals who have a higher likelihood of dying from *any* cause, as compared to other age groups.

- SARS-CoV-2 infection and subsequent infection-derived immunity will increase over time in the unvaccinated group, resulting in protection from further infection, leading to some apparent waning of VE¹⁷.
- In settings with high vaccine coverage, the risk for the remaining unvaccinated comparison group may differ from the general population in terms of risk behaviour, among other factors, resulting in distorted VE estimates.

Despite these limitations, when different methodologies, carefully employed in different settings, yield similar results by outcome, target group and vaccine platform, it provides a more consistent picture of waning VE; information which is critical for public health response and policy decisions.

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health.

As these risks evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website).

National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

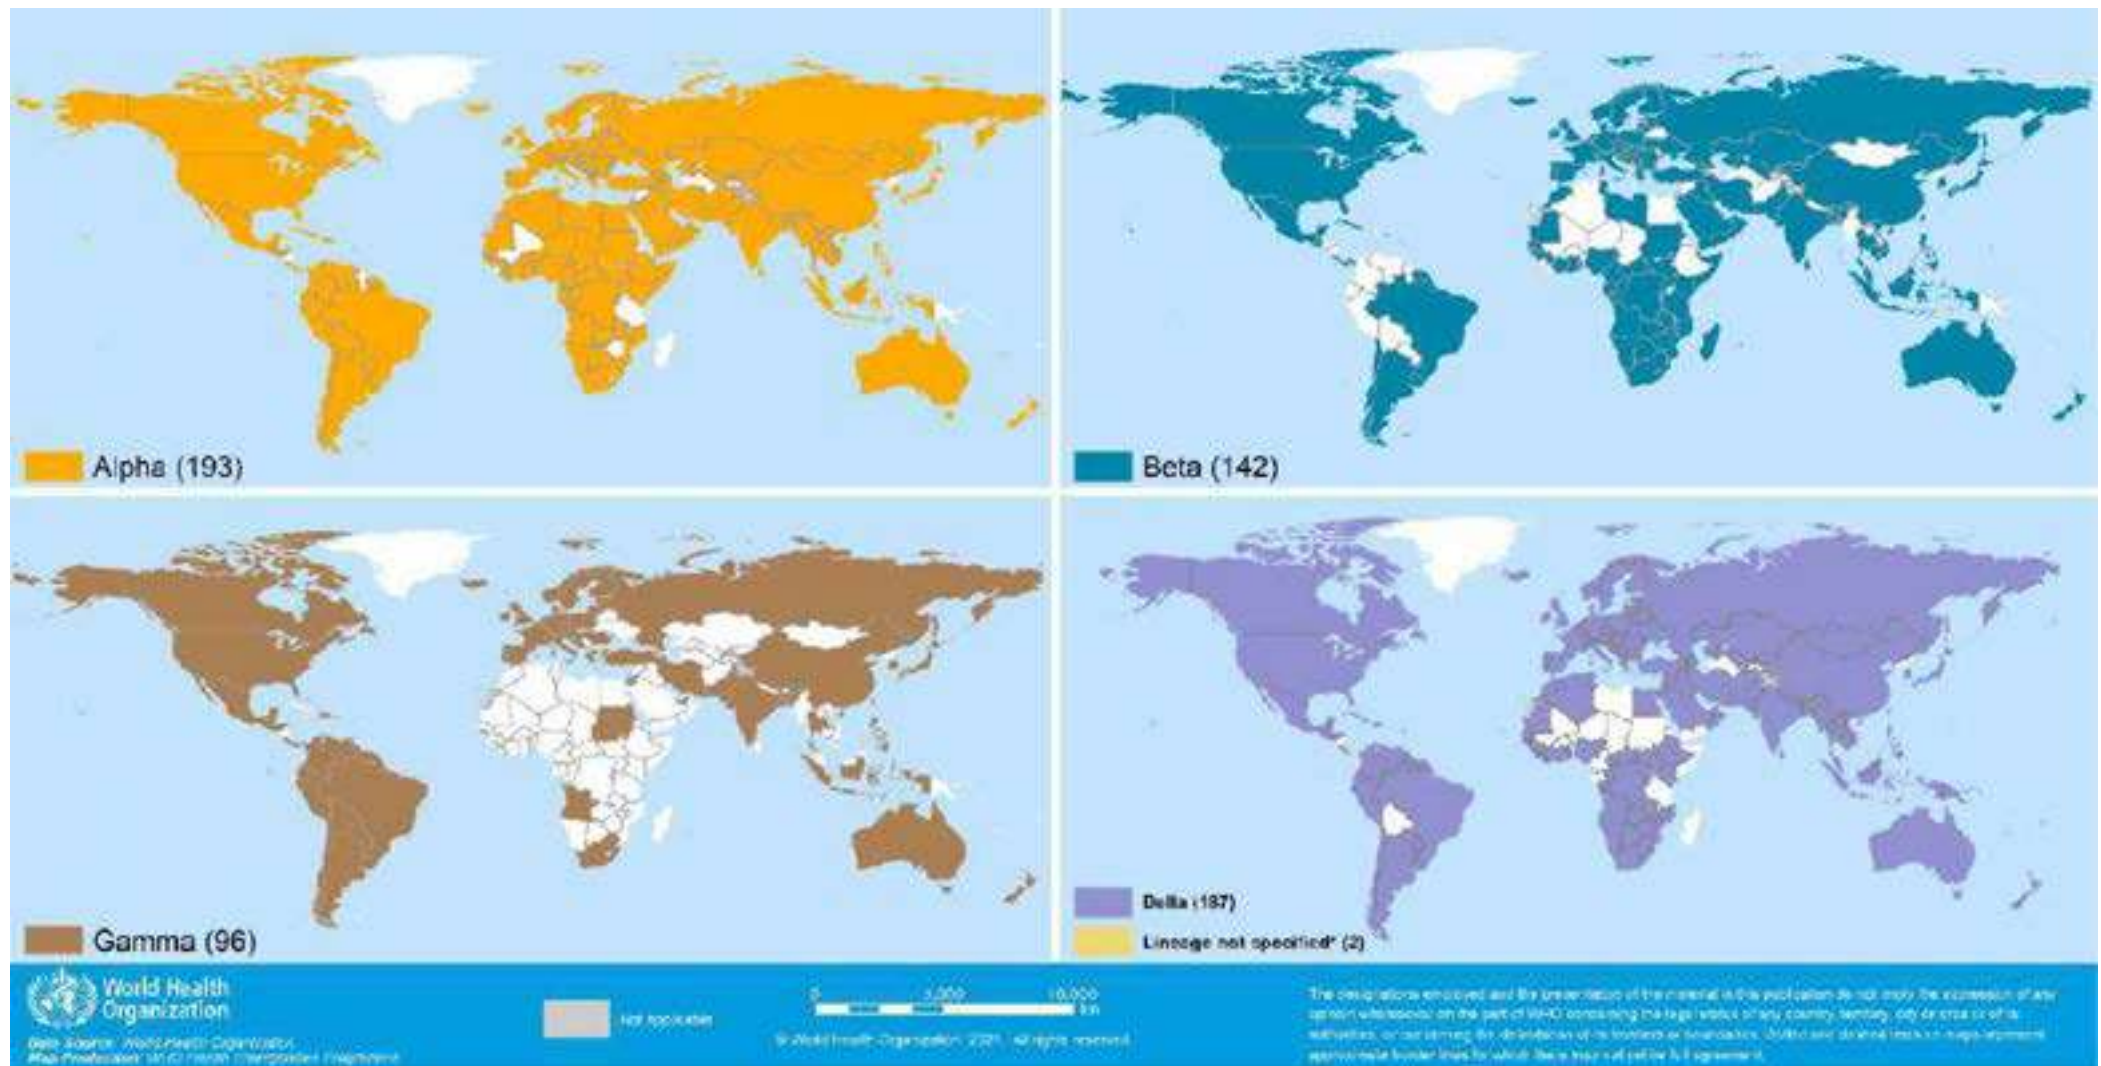

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 5, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on thorough risk assessments conducted systematically and routinely.

Figure 5. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 28 September 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see Annex 2 for further details

WHO regional overviews Epidemiological week 20 – 26 September 2021

African Region

The African Region reported over 87 000 new cases and over 2500 new deaths, a 12% decrease and a 5% increase respectively as compared to the previous week. Since the latest peak early July, the number of weekly cases has been decreasing continuously for almost three months; while weekly deaths remain elevated. Approximately one third of countries (29%; 14/49) in the Region reported an increase in new cases, ranging from 17 to 61%, highlighting the heterogeneity of trends in the Region.

The highest numbers of new cases were reported from the United Republic of Tanzania (24 307 new cases, a country which has not reported regularly), South Africa (15 627 new cases; 26.3 new cases per 100 000; a 40% decrease), and Ethiopia (8842 new cases; 7.7 new cases per 100 000; a 5% decrease). The highest numbers of new deaths were reported from South Africa (885 new deaths; 1.5 new deaths per 100 000 population; a 35% decrease), the United Republic of Tanzania (664 new deaths this week), and Ethiopia (254 new deaths; <1 new deaths per 100 000; a 22% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.2 million new cases and over 23 000 new deaths, decreases of 14% and 10% respectively as compared to the previous week. Despite the declining trend in new weekly cases and deaths, the overall epidemiological situation has not improved significantly since a surge in mid-July 2021. While the case incidence in the Region has decreased, in some countries, such as Dominica and French Guiana, the number of cases and the case incidence per 100 000 population have increased in the past week. Dominica reported 610 new cases/100 000 population this week, as compared to 361 the previous week. Similarly, French Guiana reported 510 new cases/100 000 population this week as compared to 471 the previous week.

The highest numbers of new cases were reported from the United States of America (765 827 new cases; 231.4 new cases per 100 000; a 31% decrease), Brazil (247 397 new cases; 116.4 new cases per 100 000; a 135% increase due to changes in reporting), and Mexico (66 132 new cases; 51.3 new cases per 100 000; a 13% increase). The highest numbers of new deaths were reported from the United States of America (12 312 new deaths; 3.7 new deaths per 100 000; a 17% decrease), Mexico (4165 new deaths; 3.2 new deaths per 100 000; a 13% increase), and Brazil (4090 new deaths; 1.9 new deaths per 100 000; a 10% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region continued to report decreases in case and death incidences this week, with over 209 000 new cases and over 4200 new deaths, decreases of 17% and 16% respectively as compared to the previous week. The decline in the number of weekly cases was driven by decreases reported from the three countries reporting the highest numbers of new cases: the Islamic Republic of Iran (110 868 new cases; 132.0 new cases per 100 000; a 17% decrease), Iraq (18 923 new cases; 47.0 new cases per 100 000; a 26% decrease), and Pakistan (15 627 new cases; 7.1 new cases per 100 000; a 21% decrease). Together these countries accounted for 69% of new cases reported in the Region.

A decrease in death incidence was reported from 9 of the 22 countries in the Region, including the three countries which reported the highest numbers of new deaths in the past week: the Islamic Republic of Iran (2281 new deaths; 2.7 new deaths per 100 000; a 23% decrease), Pakistan (389 new deaths; 0.2 new deaths per 100 000; an 18% decrease), and Morocco (302 new deaths; 0.8 new deaths per 100 000; a 12% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported just under 1.1 million new cases and over 14 000 new deaths, similar numbers to those reported during the previous week. For over two months, the number of new weekly cases in the Region has oscillated within range of a <5% change week-on-week, although within the Region, countries have reported varying trends. For example, case incidence in Romania and Serbia have increased sharply, while case incidence has decreased in Israel over the past month. The highest numbers of new cases were reported from the United Kingdom (230 494 new cases; 339.5 new cases per 100 000; a 14% increase), Turkey (192 778 new cases; 228.6 new cases per 100 000; a 5% increase), and the Russian Federation (145 985 new cases; 100.0 new cases per 100 000; an 8% increase).

Death incidence has plateaued over the past month, after the Region reported a gradual increase in weekly deaths from mid-July to late-August. The three countries reporting the highest numbers of new deaths in the Region accounted for 56% of the Region's deaths this week: the Russian Federation (5682 new deaths; 3.9 new deaths per 100 000; a 4% increase), Turkey (1577 new deaths; 1.9 new deaths per 100 000; an 8% decrease), and the United Kingdom (958 new deaths; 1.4 new deaths per 100 000; a 4% decrease).

Updates from the [European Region](#)

South-East Asia Region

In the South-East Asian Region, both case and death incidence have declined for the past two months. In the past week, over 344 000 new cases and 5200 new deaths were reported, decreases of 10% and 20% respectively as compared to the previous week. All but two countries in the Region have reported declines in new cases over the past several weeks. This week, the highest numbers of new cases were reported from India (204 582 new cases; 14.8 new cases per 100 000; similar to last week's figures), Thailand (85 143 new cases; 122.0 new cases per 100 000; a 10% decrease), and Indonesia (17 250 new cases; 6.3 new cases per 100 000; a 26% decrease).

Seven of the 10 countries in the Region reported a decline in weekly deaths, with notable decreases reported from Nepal (by 38%) and Indonesia (by 37%). Bhutan did not report any new deaths, while the Maldives and Timor-Leste reported similar weekly figures as last week. The highest numbers of new deaths were reported from India (2080 new deaths; <1 new deaths per 100 000; similar to last week's figures), Indonesia (999 new deaths; <1 new deaths per 100 000; a 37% decrease), and Thailand (905 new deaths; 1.3 new deaths per 100 000; a 10% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported just under 379 000 new cases and over 5200 new deaths, decreases of 15% and 24% respectively as compared to the previous week. Although the regional case incidence has continued to decline for a month, weekly incidence increased in 5 of 26 (19%) countries, including in Singapore (63% increase) and Lao People's Democratic Republic (62% increase). The highest numbers of new cases were reported from the Philippines (122 625 new cases; 111.9 new cases per 100 000; a 13% decrease), Malaysia (102 255 new cases; 315.9 new cases per 100 000; a 16% decrease), and Viet Nam (69 655 new cases; 71.6 new cases per 100 000; an 8% decrease).

While there was a marked decline in the number of weekly deaths reported this week, four countries including Singapore, New Caledonia, Mongolia and China reported over 100% increase in new deaths as compared to the previous week. The highest numbers of new deaths were reported from Malaysia (2092 new deaths; 6.5 new deaths per 100 000; a 21% decrease), Viet Nam (1543 new deaths; 1.6 new deaths per 100 000; a 16% decrease), and the Philippines (822 new deaths; <1 new deaths per 100 000; a 49% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) (WOU) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this week's edition of the COVID-19 Weekly Operational Update, published on 28 September, highlights of country-level actions and WHO support to countries include:

- Delivering 2 million syringes for Sri Lanka's COVID-19 vaccination drive
- Shipment of WHO life-saving medical supplies to Kabul, Afghanistan with support from Qatar
- WHO logistics hub airlifts largest single shipment of humanitarian cargo to Ethiopia
- WHO/Europe and Germany support children with disabilities in Belarus
- Rebooting COVID-19 response strategy and measures in Cambodia
- Expanding capacity for Integrated Disease Surveillance and Response (IDSR) in the African Region
- External Quality Assessment for laboratories testing for SARS-CoV-2
- Testing Rapid Response Mobile Laboratories (RRML) deployment procedures and minimum standards in first virtual tabletop (V-TTX) exercise for RRML/GOARN
- Connecting countries to share experiences and learnings from their COVID-19 vaccine roll-out using the mini-cPIE (COVID-19 vaccination Intra-Action Review) process
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

For more information, see the [Weekly operational update on COVID-19](#)

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

indicates that information for this variant was received by WHO from official sources.

indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

COVID-19 Weekly Epidemiological Update

Edition 58, published 21 September 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 19 September 2021

The numbers of weekly COVID-19 cases and deaths globally continued to decline this week, with over 3.6 million cases and just under 60 000 deaths reported between 13-19 September. This brings the cumulative number of confirmed cases reported globally to just under 228 million. While the African and the European Regions reported numbers of cases similar to those of the previous week, the other regions reported decreases in weekly case incidence, with substantial decreases reported in the Eastern Mediterranean (22%) and South East Asia Regions (16%).

In terms of COVID-19 mortality, nearly 60 000 deaths were reported globally in the past week, a 7% decrease as compared to the previous week. This brings the cumulative number of deaths to over 4.6 million. The African, Eastern Mediterranean and South-East Asian Regions reported decreases in weekly mortality over the past week, with the South-East Asia Region reporting the largest percentage decrease (27%). In contrast, the Western Pacific Region reported an increase (7%) in the number of new weekly deaths, while the number of deaths reported in Americas and European Regions reported was similar to that of the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 19 September 2021**

**See [Annex 2: Data, table and figure notes](#)

The regions reporting the highest weekly incidence rates per 100 000 population of cases and deaths remain the same as in the previous week: the Region of the Americas (135.5 new cases per 100 000 population; 2.4 deaths per 100 000 population) and the European Region (116.9 new cases per 100 000 population; 1.6 deaths per 100 000 population).

The highest numbers of new cases were reported from the United States of America (1 017 644 new cases; similar to last week), India (211 242 new cases; 15% decrease), the United Kingdom (203 077 new cases; 21% decrease), Turkey (183 962 new cases; 16% increase), and the Philippines (141 522 new cases; similar to last week); while the highest number of new deaths were reported from the United States of America (12 896 new deaths; 2% increase), the Russian Federation (5469 new deaths; similar to last week), Brazil (3 727 new deaths; 17% increase), Mexico (3 689 new deaths; 20% decrease), and the Islamic Republic of Iran (2 967 new deaths; 21% decrease).

Globally, cases of the Alpha variant have been reported in 193 countries, territories or areas (hereafter countries; no new country added since last two weeks), while 142 countries (one new country since last week) have reported cases of the Beta variant; and 96 countries (four new countries since last week) have reported cases of the Gamma variant. The Delta variant has been reported in 185 countries (five new countries since last week) across all six WHO regions as of 21 September.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 19 September 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 386 267 (38%)	-7%	87 874 973 (39%)	24 489 (41%)	-2%	2 170 188 (46%)
Europe	1 090 667 (30%)	-4%	68 290 457 (30%)	14 477 (24%)	1%	1 311 390 (28%)
South-East Asia	383 053 (10%)	-16%	42 498 922 (19%)	6 540 (11%)	-27%	668 468 (14%)
Eastern Mediterranean	250 781 (7%)	-22%	15 449 977 (7%)	5 074 (8%)	-20%	282 711 (6%)
Western Pacific	461 979 (13%)	-11%	7 914 374 (3%)	6 852 (11%)	7%	107 712 (2%)
Africa	98 485 (3%)	4%	5 911 505 (3%)	2 407 (4%)	-21%	142 417 (3%)
Global	3 671 232 (100%)	-9%	227 940 972 (100%)	59 839 (100%)	-7%	4 682 899 (100%)

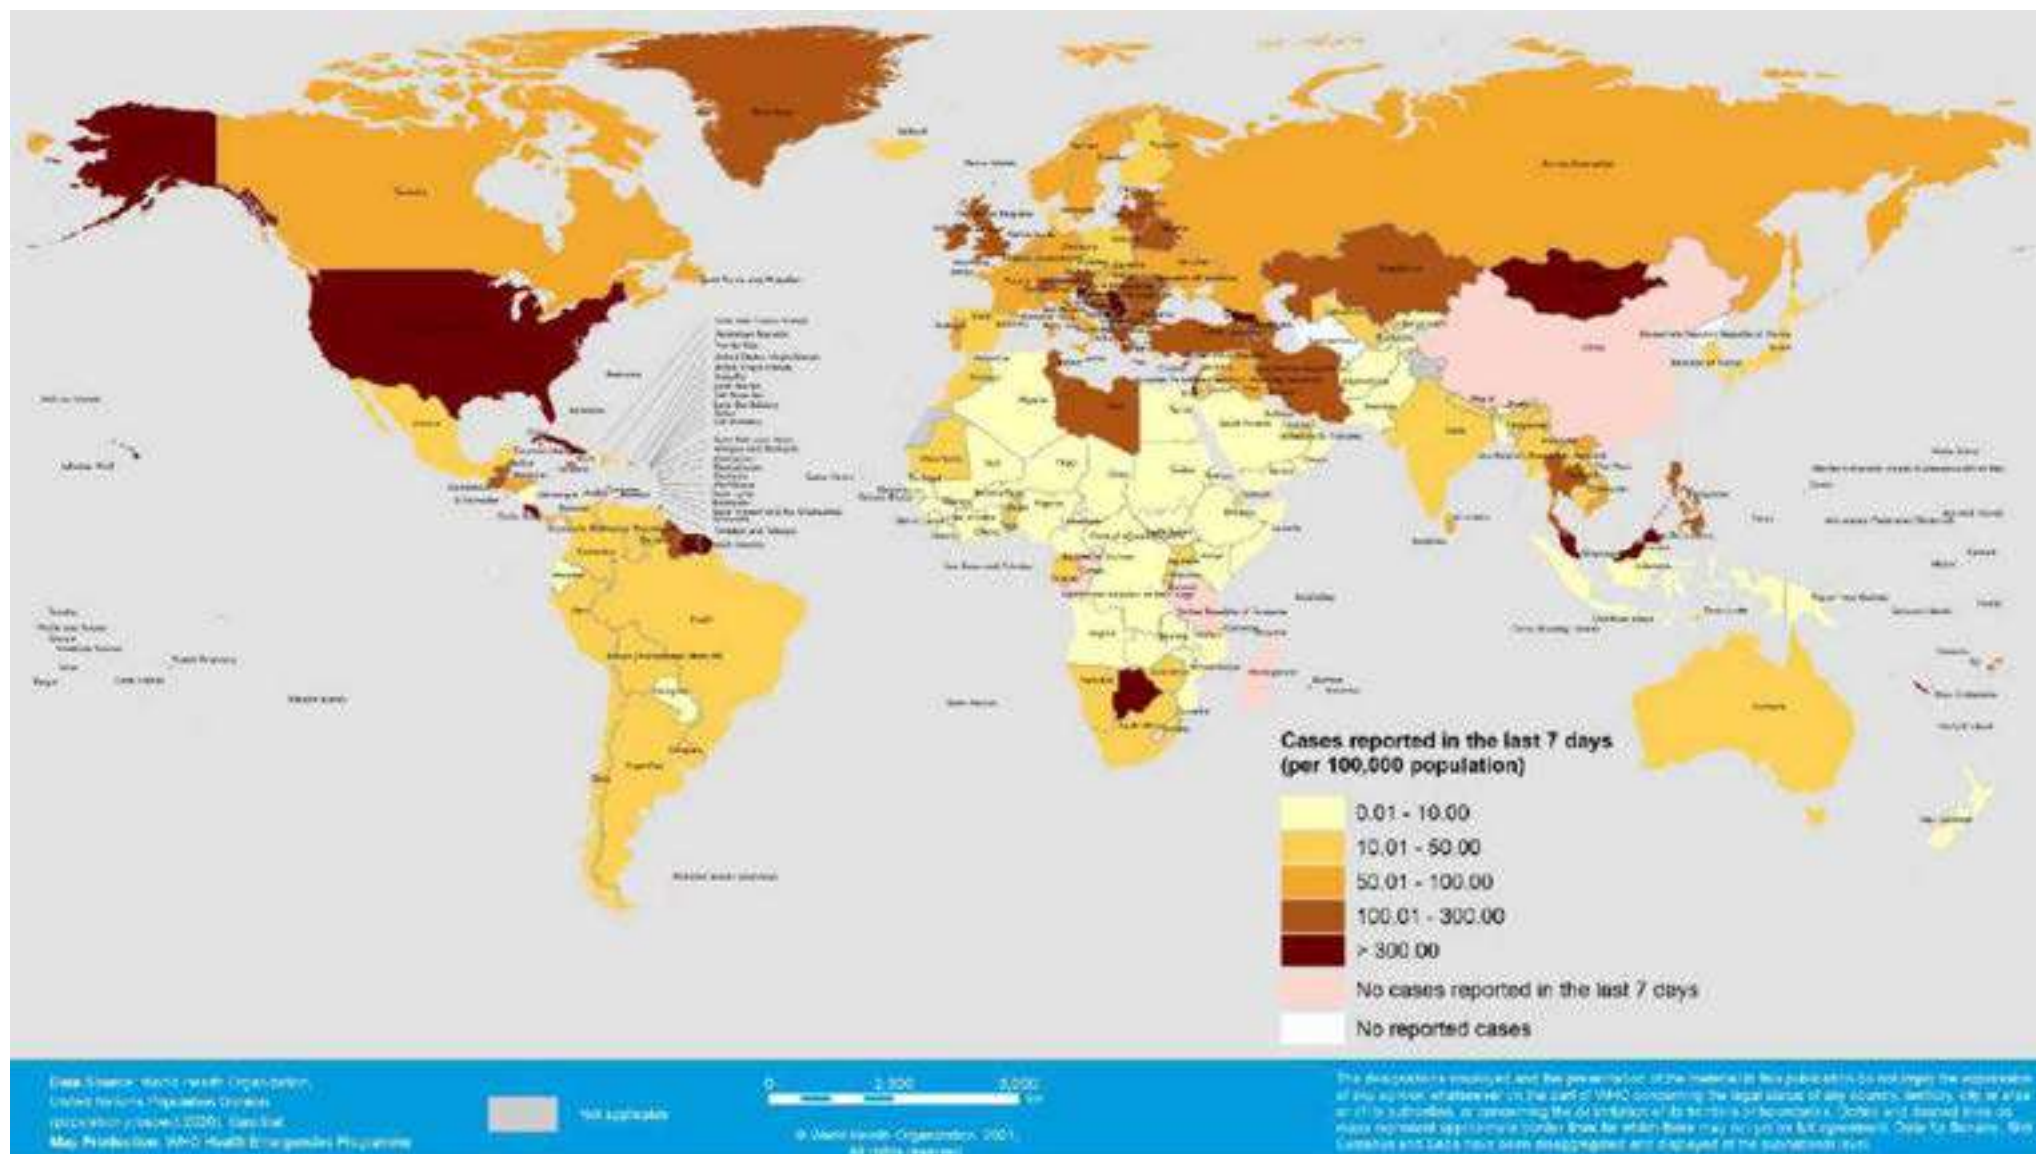

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

Updates to the WHO SARS-CoV-2 variant tracking website

Given the continuous need to understand the epidemiological and clinical impacts of VOCs and VOIs, WHO regularly monitors and reviews circulation of variants. The changes in the rise of new variants are being monitored in light of other co-circulating variants, such as Delta.

This may mean that Variants of Interest (VOIs) or Variants of Concern (VOCs) may be outcompeted by newly emerging variants, such as VOC Delta. As evidence becomes available, we will revise classifications accordingly. These revisions reflect the continuous evolution of circulating variants and their changing epidemiology (see criteria for variant classification [here](#)).

The category of ‘Alerts for further monitoring’ have been renamed ‘Variants Under Monitoring’ (VUMs). The change applies only to the name, while the definition remains the same. Primary actions by Member States and WHO following the identification of a new VUM is also outlined.

Changes to the VOI classification

As the impacts of specific SARS-CoV-2 variants on public health become better understood, WHO will continue to assess the classification of VOIs and VOCs and revise the lists accordingly. The revision described below reflect the rapid spread and current dominance of the Delta variant in most regions of the world. The Delta variant accounted for 90% of the sequences submitted to GISAID with a sample collection date (between 15 June-15 September 2021).

A variant of SARS-CoV-2 can be designated as a VOI or VOC if it meets the criteria as stated [here](#). These may also be reclassified when there is sufficient evidence suggesting that there is no major ongoing risk to global health associated with the specific variant compared to other circulating SARS-CoV-2 variants (and thus no longer meets the criteria of a VOI or VOC).

The VOIs Eta (B.1.525), Iota (B.1.526) and Kappa (B.1.617.1) have been reclassified as ‘former VOIs’ based upon the latest round of assessments, and after consultation with national and regional stakeholders, as well as in consultation with the Virus Evolution Working Group on 13 September 2021. These will now be assessed as Variants Under Monitoring. While all three variants carry mutations with suspected and/or established phenotypic impacts, the number of reported detections of these variants have decreased over time at the global, regional and country levels. Evidence from both sequencing data submitted to GISAID and information available to WHO indicate a substantial decline in their respective incidence worldwide, and therefore represent diminished public health risks relative to other VOCs and VOIs.

The WHO assessment of the impact of variants considers global risks posed by variants. At country level, national authorities may choose to continue to designate Eta, Iota and Kappa as variants of local interest. Moreover, these variants will continue to be monitored, and if their characteristics change over time, this classification will be reassessed.

Eta (B.1.525) has been detected in 81 countries since it was initially identified in December 2020. It was designated as a VOI on 17 March 2021. This variant has shown a limited reduction in neutralizing activity of sera of vaccinated individuals, comparable to the reduction observed for the Delta variant. Since a peak in circulation in April 2021 of 0.8% of the sequences submitted to GISAID, there has been a continuous decline in the detection of this variant. Sequencing data submitted to GISAID and information from WHO Regional Offices indicate that the prevalence of Eta has remained very low at a global, regional and country level since July 2021.

Iota (B.1.526) was first identified in the United States of America (USA) in November 2020. It was designated as a VOI on 24 March 2021, following an increase in the number of sequences submitted to GISAID across several countries (identified in at least 49 countries). Roughly half of the sequences of this variant contains the E484K mutation in the spike, and one third contain the S477N change, but those two changes are practically never seen together in this variant. By April 2021, the proportion of this variant to overall sequences submitted to GISAID reached a peak of just over 3%, with the majority of sequences being reported from the USA. Since then, the proportion of this variant has declined continuously. Sequencing data from the USA shows a significant and continued decline in the proportion of Iota, which has only been found in very sporadic cases since late July 2021.

Kappa (B.1.617.1) was first reported by India in early October 2020 and has since spread to 57 countries. It was designated as a VOI on 4 April 2021. Like the Delta variant, this variant has the spike mutation P681R, which is thought to increase the transmissibility of the variant. Kappa shares a common parent lineage with Delta, but Delta has additional notable amino acid changes in the spike protein. Also similar to Delta, Kappa shows a limited reduction in the neutralizing activity of convalescent sera and sera of vaccinated individuals. Kappa reached a peak of 1% of all sequences submitted to GISAID in April 2021 but has since shown a steep and continuous decline in the proportion of submitted sequences. Sequencing data submitted to GISAID and information available to WHO indicate that the prevalence of Kappa at a global and country levels has remained very low since July 2021. This decline to very low to no circulation was also observed in regions of India that had previously experienced high transmission of this variant, such as Maharashtra.

List of current VOIs

The revised list of current VOIs now includes Lambda and Mu variants, both circulating in Latin America, where the Delta variant has begun to circulate but has not yet become dominant. The epidemiology of these VOIs, particularly considering the co-circulation of the Delta variant, will continue to be monitored closely.

Updates on VOCs and VOIs, and a list of VUMs, are available on the [WHO Tracking SARS-CoV-2 Variants website](https://www.who.int/tracking-sars-cov-2/variants).

Guidance for surveillance of SARS-CoV-2 variants

On 9 August 2021, WHO published an [interim guidance document on surveillance of SARS-CoV-2 variants](#). The document aims to describe a minimum set of surveillance activities recommended at the national level to detect and monitor the relative prevalence of SARS-CoV-2 variants and outlines a set of activities for the characterization and assessment of risk posed by these variants. A set of indicators is also provided to standardize monitoring and public reporting of variant circulation.

The document is primarily intended for national and sub-national public health authorities and partners who support implementation of SARS-CoV-2 variant surveillance. It complements the interim guidance on [Public health surveillance for COVID-19](#), which provides overall guidance for public health surveillance of coronavirus disease 2019 (COVID-19) in humans. Additional guidance has been published for laboratory stakeholders on [diagnostic testing for SARS-CoV-2](#) and [sequencing for public health goals](#), alongside an [implementation guide for SARS-CoV-2 sequencing](#).

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of these COVID-19 Weekly Epidemiological Updates. Since the last detailed update on 7 September, there are several new publications on the phenotypic characteristics of VOCs.

An observational preprint study conducted in a tertiary care hospital setting in India compared the surge in cases recorded from March to December 2020 to that in January to July 2021 when the Delta variant was in circulation. Preliminary results from the study found that the median (IQR) length of stay during pre-Delta Vs Delta circulation period was [7 (5-10) vs 8 (6-10) days] and ICU stay [6 (2-10) vs 9 (5-13) days].¹ In-hospital deaths were 1.84 times higher during the period of Delta circulation (95% CI: 1.32-2.55), which did not change significantly after adjusting for age and sex (adjusted odds ratio, 95% CI: 2.03, 1.44-2.86), and age, sex and comorbidities (adjusted odds ratio 95% CI: 2.09, 1.47-2.95). However, the study should be interpreted carefully as these are preliminary results. To note, the hospitalization rates pre-and post-emergence of Delta variant were also influenced by government policies as people were encouraged to seek hospital care during pre-emergence period (March to December 2020) while home-based isolation was promoted widely during the circulation of Delta variant, partly due to the pressure on the health-care systems and the lack of available beds in many hospitals.

An ecological peer-reviewed study using the Ministry of Health Influenza Epidemiological Surveillance Information System, analyzed the mortality in the state of Amazonas, Brazil over two periods: prior to circulation of the Gamma variant (April to May 2020) when B.1.1.28, B.1.1.29, B.1.1.33 were in circulation and

when Gamma started to predominate (January 2021). The study did not include the month of December 2020 when old lineages were replaced by Gamma.² The study found higher incidence and an increased proportion of COVID-19 cases in younger age groups (20- 39 years old) during the circulation of the Gamma variant. Additionally, when comparing the pre- and post-emergence of the Gamma variant, there was an increase in the proportion of women among cases of Severe Acute Respiratory Infection (SARI) (40% vs. 47%), as well as among those who died (34% vs. 47%). The case fatality rate (CFR) among those infected with the Gamma variant who were hospitalized between the age of 20-39-year-old was 2.7 times greater than the rate observed prior (between April to May 2020; pre-Gamma circulation) for both males and females. The CFR ratios in the general population were 1.15 (95% CI: 1.1-1.2) in females and 0.78 (95% CI: 0.7-0.8) in males. These findings suggest greater severity of disease for those infected with the Gamma variant among young adults of both sexes and the general female population. It is important to note that mortality was greatly influenced by the significant pressure on the health care system, which could have contributed to the increase in mortality, case fatality and hospital mortality, however, the study did not find a homogeneous increase across age groups by sex as was observed during the period prior to Gamma circulation. Further studies are needed to better understand the variant profile and their impact.

An observational preprint study from one Brazilian state investigated the proportion of reinfections due to Gamma variant using estimates from regular blood donors in Amazona's capital, Manaus.³ A total of 223 samples were included in the study. Using the serological definition of reinfection, the study found that 13.6% (CI 95%: 7% - 24.5%) of all presumed Gamma infections that were observed in 2021 were reinfections. When probable or possible reinfections were included, these percentages increased to 22.7% (95% CI 14.3% - 34.2%) and 39.3% (95% CI 29.5% - 50.0%) respectively. Previous infection conferred a protection against reinfection by 85.3% (95% CI 71.3% - 92.7%), decreasing to 72.5% (95% CI 54.7% - 83.6%) and 39.5% (95% CI 14.1% - 57.8%), respectively, if probable and possible reinfections are included. The study concluded that the estimated rates of reinfection suggest that the Gamma variant may induce a higher reinfection risk than previous non-Gamma variants. These results reinforce the concerns over the risk of reinfection with continuous virus evolution. However, the study did not sample donors frequently enough to detect all potential reinfections which may have led to possible non detection of reinfection.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility ⁴	Increased transmissibility ^{5,6}	Increased transmissibility ^{6,7}	Increased transmissibility and secondary attack rate ^{6,8}
Disease severity	Increased risk of hospitalization ⁹ , possible increased risk of severity and mortality ^{10,11}	Not confirmed, possible increased risk of in-hospital mortality ¹²	Possible increased risk of hospitalization ¹³ , risk of severity ²	Increased risk of hospitalization ^{14,15}
Risk of reinfection	Neutralizing activity retained ¹⁶ , risk of reinfection remains similar ¹⁷	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ¹⁸	Moderate reduction in neutralizing activity reported ¹⁹	Reduction in neutralizing activity reported ^{20–22}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF); no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed ²³	No impact on RT-PCR or Ag RDTs observed ²²	None reported to date	None reported to date

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision*

VE refers to vaccine effectiveness and vaccine efficacy

Summary of VE*: indicates the general conclusions but only for the vaccines evaluated against the specific variant

Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used.

“Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the VIEW-hub Resources page (<https://view-hub.org/resources>). For individual vaccine effectiveness studies, see ‘COVID-19 Vaccine Effectiveness Results Summary’, reference numbers noted with a ‘#’. For a list of all neutralization studies, see ‘COVID-19 Vaccine Neutralization Studies Table’.

References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table and are included in the reference section below.

Additional notes on VOC impacts on vaccines

- Studies presenting VOC-specific vaccine efficacy or effectiveness (VE) estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, due to instability or lack of phase 3 RCT estimates for these outcomes, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for infection (when a phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Some VE estimates may not be included in the table above when it is not possible to tease out the effect of waning from the effect of variants on vaccine performance.

Table 3 presents the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to VE in non-VOC settings. Of note, reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of $\sim 85\%$. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection, as is the case for AstraZeneca-Vaxzevria.

Since the latest update published on 07 September, there have been six further publications assessing vaccine effectiveness against SARS-CoV-2 VOC.

A test-negative case-control study (pre-print) from Public Health England used UK national surveillance data, adjusting for multiple potential confounders, to assess the effectiveness of Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273, and AstraZeneca-Vaxzevria over time separately for Alpha and Delta variants among persons 16 years and older.³¹ VE against symptomatic disease up to 10+ weeks post full vaccination was higher for Alpha than Delta for both Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria. VE against Alpha symptomatic disease 2-9 weeks post full vaccination was 95.0% (95% CI: 93.8-96.0%) and 81.9% (79.2-84.3%) for Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria, respectively, whereas VE against Delta symptomatic disease 2-9 weeks post full vaccination was 89.8% (89.6-90.0%) and 66.7% (66.3-67.0%), respectively. VE of 2 doses of Moderna-mRNA-1273 against Delta symptomatic disease 2-9 weeks post full vaccination was 100% (no comparable estimate was available for Alpha). Results show that VE against symptomatic disease due to Delta peaked in the first weeks after full vaccination and then declined to 69.7% (95% CI: 68.7-70.5%) for Pfizer BioNTech-Comirnaty and 47.3% (45-49.6%) for AstraZeneca-Vaxzevria by 20+ weeks post full vaccination. Because Delta rapidly replaced Alpha in the UK, assessment of Alpha VE against symptomatic disease at 20+ weeks was not possible. Protection against hospitalisation and death due to Delta remained high for at least 20 weeks after the second dose of for Pfizer BioNTech-Comirnaty with VE estimates of 92.7% (90.3-94.6%) and 90.4 (85.1 to 93.8), respectively. Some waning of protection against hospitalization and death was observed for AstraZeneca-Vaxzevria with VE estimates of 77.0 (70.3-82.3%) and 78.7 (52.7 to 90.4), respectively, 20+ weeks post second dose. Authors also found greater waning among

those ≥ 65 years of age and those 40-64 years of age in clinical risk groups for both Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria.

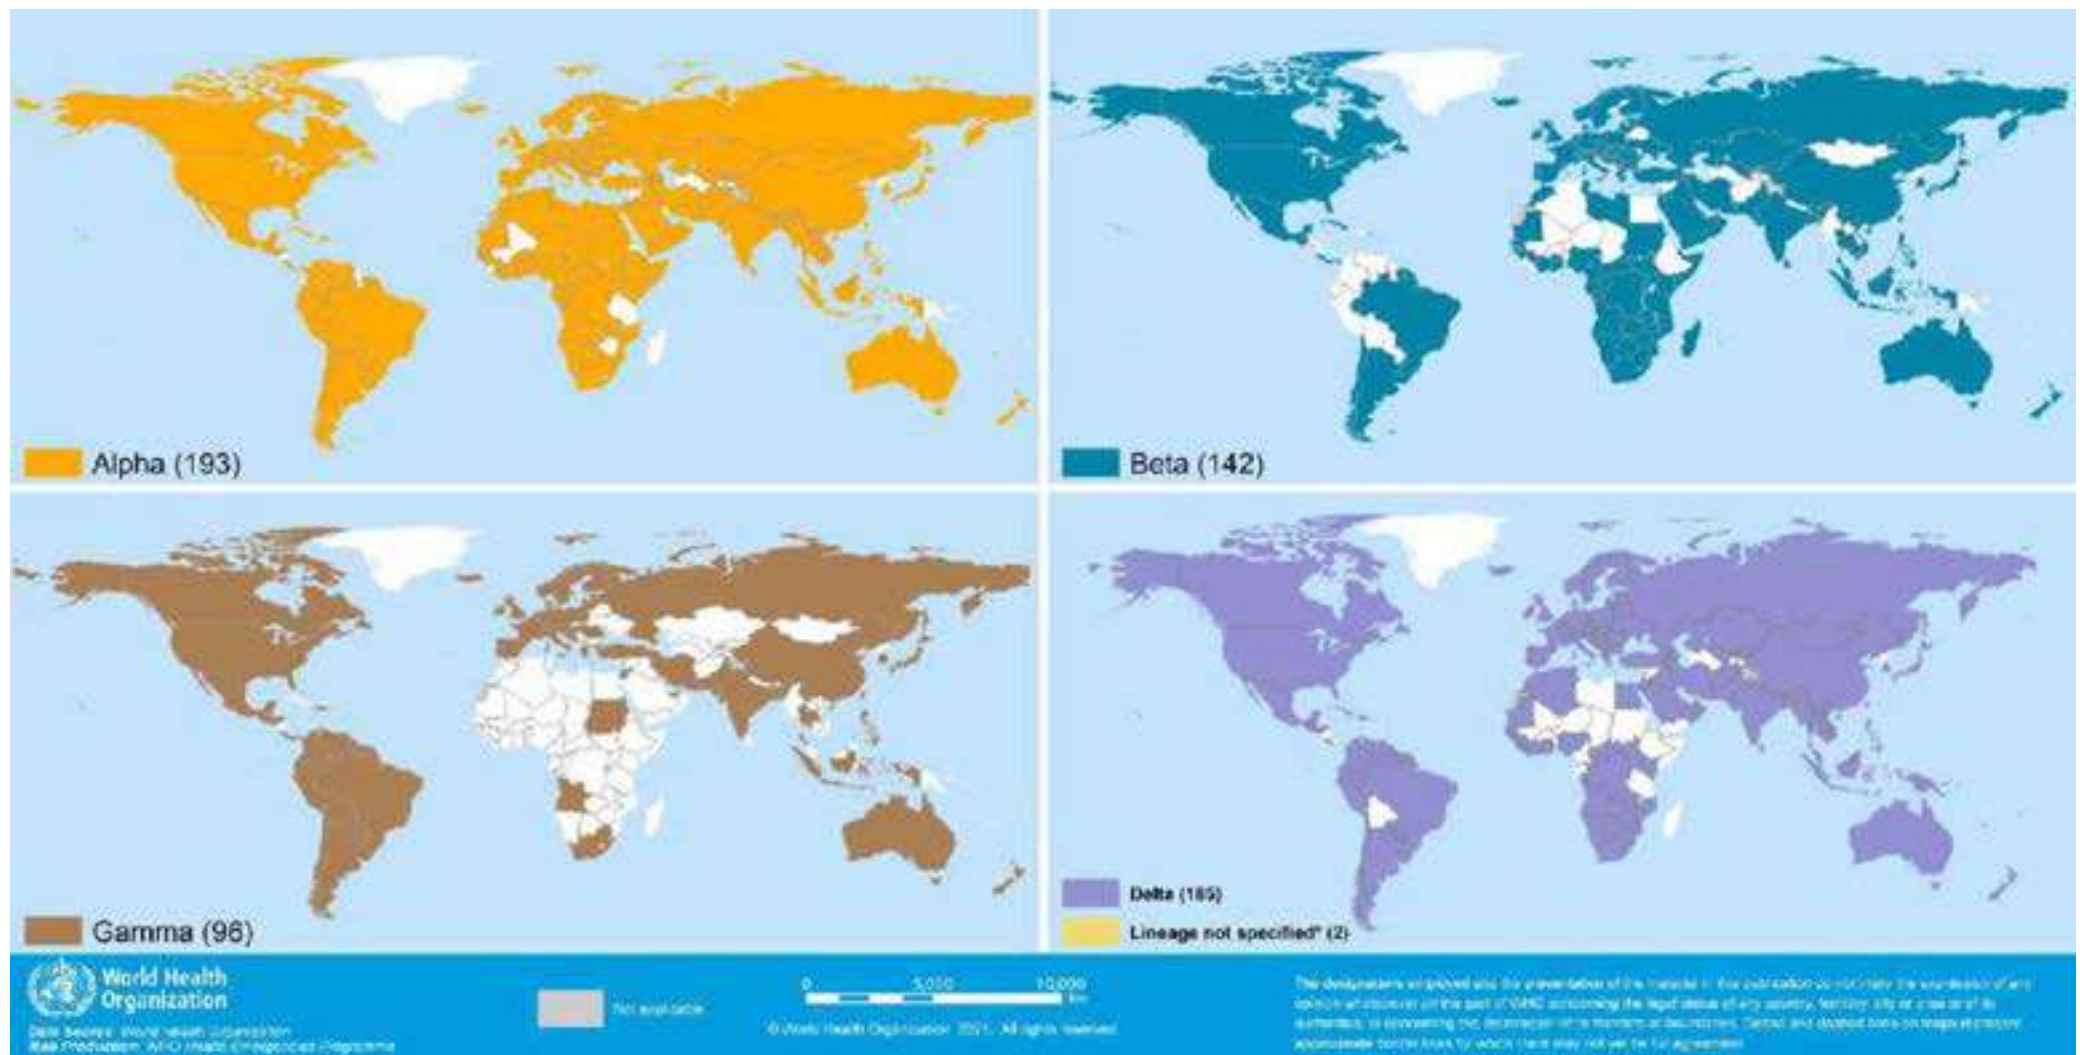

Five studies (including peer-reviewed journals and preprint) from the USA assessed VE of COVID-19 vaccines during periods of high Alpha and/or high Delta prevalence. A retrospective cohort study linking insurance claims data to health data sources assessed the effectiveness of Janssen-Ad26.COVS vaccine in preventing SARS-CoV-2 infection and hospitalization among persons 18 years and older for periods of high Alpha and Delta prevalence.³² VE against infection was similar during both periods: 79% (77-80%) during the Alpha period and 78% (73-82%) during the Delta period. VE against hospitalization was also similar: 81% (79-84%) vs. 85% (73-91%) for Alpha and Delta periods, respectively. A second study used a test-negative design to evaluate the VE of mRNA vaccines against hospitalization among patients presenting with COVID-19-like illness at 5 Veterans Affairs medical centers. The VE of mRNA vaccines (Pfizer BioNTech-Comirnaty or Moderna-mRNA-1273) against hospitalization was similar during February-June 2021 when Alpha was the predominant variant (84.1%, 95% CI: 74.1-90.2%) and July-August 2021 when Delta was predominant (89.3%, 95% CI: 80.1-94.3%). A third study using the test-negative design evaluated the effectiveness of Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273, and Janssen-Ad26.COVS vaccines among adults 18 years and older across nine states from June-July 2021 when Delta was the predominant variant in the USA.³³ VE against hospitalization 14 or more days after receipt of the final dose was 80% (73-85%), 95% (92-97%), and 60% (31-77%) for Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273, and Janssen-Ad26.COVS, respectively. Similar VEs were observed for emergency and urgent care visits. Authors note these VE estimates were similar to those during the months before Delta became predominant as noted in two previous publications.^{34,35} A fourth study also used a test-negative design to evaluate VE of mRNA vaccines and Ad26.COVS-Janssen against SARS-CoV-2 infection among persons ≥ 15 years in Oregon during July 2021, when Delta accounted for $>75\%$ of sequenced cases in the state.³⁶ VE of 2 doses of mRNA vaccines was 74% (65-82%); VE of 1 dose of Janssen-Ad26.COVS was 51% (-2-76%). Authors note that the VE estimate for mRNA vaccines are reduced compared to June 2021 when Delta accounted for only 4% of sequenced viruses (VE of 84%, 95% CI: 60-94), suggesting reduced VE against infection of the Delta variant, though confidence intervals overlapped. The VE estimate for Janssen-Ad26.COVS during June was unstable due to small numbers. Finally, a retrospective cohort study in Minnesota found slightly reduced VE of mRNA vaccines against asymptomatic SARS-CoV-2 infection during June-August when Delta was predominant, as compared to April-May when Alpha was predominant: 63% (44-76%) vs. 71% (53-83%), though confidence intervals overlap.³⁷ Note that studies that compare VE against Alpha from an earlier time period with Delta from a later time period might be confounded by waning VE over time.

Together these studies provide evidence that VE of mRNA vaccines, AstraZeneca-Vaxzevria, and Ad26.COVS-Janssen against severe disease outcomes due to Delta is high and similar to that of Alpha, with evidence of no-to-minimal waning for these severe outcomes to date. Consistent with previous research, the majority of studies described in this issue suggest that VE of these vaccines against symptomatic disease, infection, and asymptomatic disease may be reduced for Delta compared to Alpha; with waning VE against symptomatic disease apparent for Delta variant in the UK study that provided longitudinal VE estimates.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 21 September 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see Annex 2 for further details

WHO regional overviews Epidemiological week 13 – 19 September 2021

African Region

The African Region reported over 98 000 new cases, a case incidence similar to that of the previous week, following a consistent decline in the number of new weekly cases over the past two months. While most of the countries in the region reported a decline in case incidence, several countries reported an increase including Botswana, Burundi and Zimbabwe. The majority of countries in the region reported a decline in the number of new deaths last week.

The highest numbers of new cases were reported from South Africa (26 115 new cases; 44 new cases per 100 000 population; 35% decrease), Uganda (22 511 new cases; 49.2 new cases per 100 000), and Ethiopia (9266 new cases; 8.1 new cases per 100 000; figures similar to those of the previous week). The highest numbers of new deaths were reported from South Africa (1365 new deaths; 2.3 new deaths per 100 000 population; 14% decrease), Ethiopia (208 new deaths; <1 new deaths per 100 000, 18% increase), and Algeria (112 new deaths; <1 new deaths per 100 000; 39% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.3 million new cases and over 24 000 new deaths in the past week, a 7% decrease in the number of cases and a number of new deaths similar to that of the previous week. While the majority of countries in the Region reported a decline in weekly case incidence, several countries including Canada, Chile and Suriname reported an increase over the past week. Nearly a third of countries in the Region reported an increase in the number of new deaths in the past week.

The highest numbers of new cases were reported from the United States of America (1 017 644 new cases; 307.4 new cases per 100 000; similar to the numbers reported last week), Brazil (105 369 new cases; 49.6 new cases per 100 000; 11% decrease), and Mexico (58 751 new cases; 45.6 new cases per 100 000; 34% decrease). Similarly, the highest numbers of new deaths were reported from the United States of America (12 896 new deaths; 3.9 new deaths per 100 000; similar to the numbers reported last week), Brazil (3727 new deaths; 1.8 new deaths per 100 000; 17% increase), and Mexico (3689 new deaths; 2.9 new deaths per 100 000; 20% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported a marked decrease of 22% in the number of new weekly cases, with over 250 000 new cases reported this week as compared to the previous week. Although the regional case incidence has continued to decline for over a month, weekly incidence increased in five of 22 (23%) countries in the past week, including in Djibouti, Syrian Arab Republic, and Egypt. The highest numbers of new cases were reported from the Islamic Republic of Iran (133 293 new cases; 158.7 new cases per 100 000; 23% decrease), Iraq (25 494 new cases; 63.4 new cases per 100 000; 27% decrease), and Pakistan (19 894 new cases; 9 new cases per 100 000; 23% decrease).

Similarly, weekly deaths have continued to decline for past three weeks, with over 5000 new deaths reported this week, a 20% decrease as compared to the previous week. The highest numbers of new deaths were reported from the Islamic Republic of Iran (2967 new deaths; 3.5 new deaths per 100 000; 21% decrease), Pakistan (473 new deaths; <1 new deaths per 100 000; 14% decrease), and Morocco (342 new deaths; <1 new deaths per 100 000; 31% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

In the European Region, the weekly incidence in both cases and deaths remained similar to rates reported in the previous week, with just under 1.1 million new cases and over 14 000 new deaths reported this week, as compared to the previous week. The highest numbers of new cases were reported from the United Kingdom (203 077 new cases; 299.1 new cases per 100 000; 21% decrease), Turkey (183 962 new cases; 218.1 new cases per 100 000; 16% increase), and the Russian Federation (134 858 new cases; 92.4 new cases per 100 000; 6% increase).

The highest numbers of new deaths were reported from the Russian Federation (5469 new deaths; 3.7 new deaths per 100 000; similar to last week), Turkey (1718 new deaths; 2 new deaths per 100 000; a 5% decrease), and the United Kingdom (1003 new deaths; 1.5 new deaths per 100 000; similar to last week).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 383 000 new cases and over 6500 new deaths, decreases of 16% and 27% respectively as compared to the previous week. Incidence of cases and deaths has declined for nearly two months, with all countries in the Region reporting a decrease in weekly cases for the past two weeks. This week, notable decreases were reported in Timor-Leste (by 42% for cases and 40% for deaths) and Indonesia (by 40% for cases and 48% for deaths) as compared to last week. The highest numbers of new cases were reported from India (211 242 new cases; 15.3 new cases per 100 000; 15% decrease), Thailand (94 304 new cases; 135.1 new cases per 100 000; 7% decrease), and Indonesia (23 252 new cases; 8.5 new cases per 100 000; 40% decrease).

The highest numbers of new deaths were reported from India (2183 new deaths; <1 new deaths per 100 000; similar to last week), Indonesia (1579 new deaths; <1 new deaths per 100 000; a 48% decrease), and Thailand (1010 new deaths; 1.4 new deaths per 100 000; a 33% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Case incidence in the Western Pacific Region has decreased for past three weeks, with just under 462 000 new cases reported this week, a 11% decrease as compared to the previous week. There were notable decreases in weekly case incidence reported in Japan (45%) and French Polynesia (43%). The highest numbers of new cases were reported from the Philippines (141 522 new cases; 129.1 new cases per 100 000; similar to last week), Malaysia (122 376 new cases; 378.1 new cases per 100 000; a 10% decrease), and Viet Nam (75 674 new cases; 77.7 new cases per 100 000; a 16% decrease).

Weekly deaths have continued to increase since early July 2021, with notable increases reported in New Caledonia (by 2000%), Papua New Guinea (by 225%) and Mongolia (by 143%). The highest numbers of new deaths were reported from Malaysia (2648 new deaths; 8.2 new deaths per 100 000; similar to last week), Viet Nam (1839 new deaths; 1.9 new deaths per 100 000; 17% decrease), and the Philippines (1605 new deaths; 1.5 new deaths per 100 000; 75% increase).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) (WOU) is a report provided by the COVID-19 Strategic Preparedness and Response Plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this week's edition of the COVID-19 Weekly Operational Update, published on 20 September, highlights of country-level actions and WHO support to countries include:

- Delivering 2 million syringes for Sri Lanka's COVID-19 vaccination drive
- Shipment of WHO life-saving medical supplies to Kabul, Afghanistan with support from Qatar
- WHO logistics hub airlifts largest single shipment of humanitarian cargo to Ethiopia
- WHO/Europe and Germany support children with disabilities in Belarus
- Rebooting COVID-19 response strategy and measures in Cambodia
- Expanding capacity for Integrated Disease Surveillance and Response (IDSR) in the African Region
- External Quality Assessment for laboratories testing for SARS-CoV-2
- Testing Rapid Response Mobile Laboratories (RRML) deployment procedures and minimum standards in first virtual tabletop (V-TTX) exercise for RRML/GOARN
- Connecting countries to share experiences and learnings from their COVID-19 vaccine roll-out using the mini-cPIE (COVID-19 vaccination Intra-Action Review) process
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

For more information, see the [Weekly operational update on COVID-19](#)

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

hat information for this variant was received by WHO from official sources.

ation become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community).

Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

*** Alpha was excluded for Comoros this week based on further information.

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 57, published 14 September 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [Special focus: COVID-19 in children and adolescents](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 12 September 2021

With nearly 4 million new cases reported globally in the past week (6-12 September), this represents the first substantial decline in weekly cases in more than two months (Figure 1). All regions reported declines in new cases as compared to the previous week.

The number of deaths reported globally in the past week also decreased as compared to previous week, with just over 62 000 new deaths. The African Region reported an increase in the number of weekly deaths (7%), while the South-East Asia Region reported the largest decrease (20%). The American and Eastern Mediterranean Regions reported slightly smaller decreases, 9% and 6% respectively, while the numbers of deaths reported in the European and the Western Pacific Regions were similar to last week. The cumulative number of cases reported globally is now over 224 million and the cumulative number of deaths is just over 4.6 million.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 12 September 2021**

**See [Annex 2: Data, table and figure notes](#)

The regions reporting the highest weekly incidence rates per 100 000 population of cases and of deaths remain the same as in the previous week: the Region of the Americas (143 new cases per 100 000 population; 2.3 deaths per 100 000 population) and European Region (119.4 new cases per 100 000 population; 1.5 deaths per 100 000 population).

The highest numbers of new cases were reported from the United States of America (1 034 836 new cases; 20% decrease), the United Kingdom (256 051 new cases; 5% increase), India (248 248 new cases; 15% decrease), the Islamic Republic of Iran (172 030 new cases; 17% decrease), and Turkey (158 236 new cases; 6% increase).

Globally, cases of the Alpha variant have been reported in 193 countries, territories or areas (hereafter countries; no new country added since last week), while 142 countries (one new country since last week) have reported cases of the Beta variant; and 96 countries (four new countries since last week) have reported cases of the Gamma variant. For the Delta variant, since it was first reported in October 2020, it has been reported in 180 (six new countries since last week) countries across all six WHO regions as of 14 September.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 12 September 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 462 450 (37%)	-17%	86 462 003 (39%)	23 689 (38%)	-9%	2 144 336 (46%)
Europe	1 113 722 (28%)	-5%	67 170 804 (30%)	14 117 (23%)	-2%	1 296 421 (28%)
South-East Asia	453 539 (12%)	-16%	42 115 869 (19%)	8 938 (14%)	-20%	661 928 (14%)
Eastern Mediterranean	319 572 (8%)	-15%	15 199 196 (7%)	6 358 (10%)	-6%	277 637 (6%)
Western Pacific	487 586 (12%)	-8%	7 418 755 (3%)	6 410 (10%)	2%	100 860 (2%)
Africa	94 352 (2%)	-15%	5 813 020 (3%)	3 034 (5%)	7%	140 010 (3%)
Global	3 931 221 (100%)	-13%	224 180 411 (100%)	62 546 (100%)	-7%	4 621 205 (100%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health.

As variants evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website).

National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

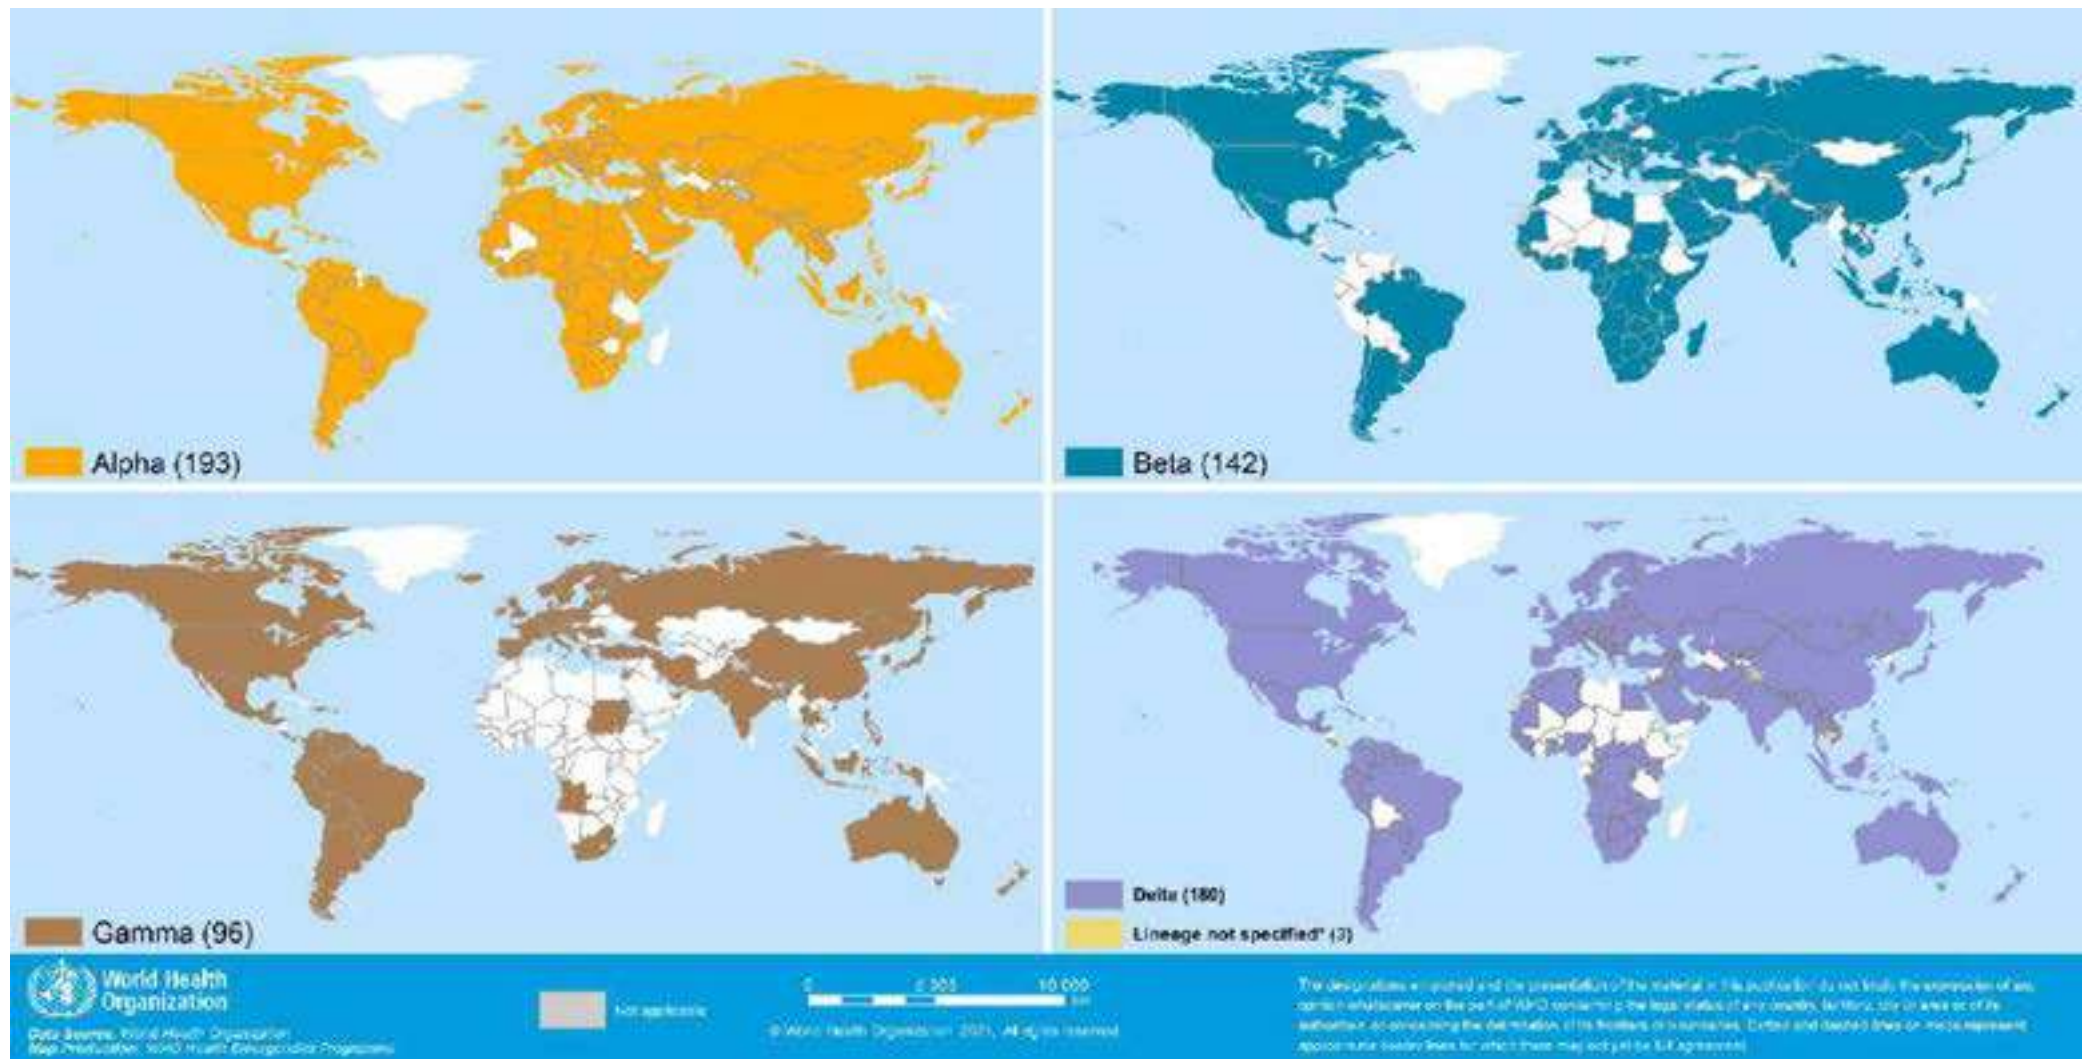

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries, territories or areas (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on thorough risk assessments conducted systematically and routinely.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 14 September 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see Annex 2 for further details

Special Focus: COVID-19 in children and adolescents

SARS-CoV-2 infections among children and adolescents typically cause less severe illness and fewer deaths as compared to adults. While a less severe course of disease is a positive outcome, there are concerns that mild symptoms may have led to less testing, resulting in fewer identified cases of SARS-CoV-2 infection in children and adolescents. If children and adolescents with mild or no symptoms also transmit the disease, they may also contribute to transmission in the community. Consequently, understanding symptoms, infectivity and patterns of SARS-CoV-2 transmission in children and adolescents is essential for developing, adapting and improving control measures for COVID-19 across all ages, especially since vaccination is not currently available or authorized for those under the age of 12 years in most contexts.

This report summarizes the current knowledge around SARS-CoV-2 infection acquisition and transmission and COVID-19 disease in children under the age of five years, older children (5 to 9 years old), younger adolescents (10 to 14 years old) and older adolescents (15 to 19 years old). Some information on incidence and mortality is also provided for young adults (20 to 24 years old). It aims to inform decisions, based on local contexts, on how best to keep schools, kindergarten and day-care facilities open and what advice to apply to intergenerational mixing.

Incidence and mortality in children, adolescents and young adults

Overall, there are proportionally fewer cases and deaths from COVID-19 among children, adolescents and young adults as compared to adults (Table 1). Based on age-disaggregated case data [reported to WHO](#) from 30 December 2019 to 6 September 2021¹, the proportion of global cases increased with age category: children under the age of five represented the smallest proportion of cases among individuals up to 24 years old, while older adolescents (15 to 19 years old) and young adults (20 to 24 years old) grouped together had the highest proportion of the global cases. Deaths for all age groups represented less than 0.5% of the proportion of global deaths.

Table 1. Global epidemiological overview on children and adolescents (information from 30 December 2019 to 06 September 2021; Data cleaning is continuous, please interpret with caution).

Age group	Number of cases	Proportion (%) to global cases*	Number of deaths	Proportion (%) to global deaths**
<5 years	1 599 073	1.8	1704	0.1
5 to 14 years	5 622 295	6.2	1218	0.1
15 to 24 years	13 071 320	14.3	6327	0.4

*Total global cases reported to WHO through case-based reporting, all ages: 90 011 040

**Total global deaths reported to WHO through case-based reporting, all ages: 1 752 008

What are the symptoms of COVID-19 in children and adolescents?

Younger children (under five years old), older children and adolescents (10 to 19 years old) usually have fewer and milder symptoms of SARS-CoV-2 infection than adults >25 years old and are less likely than adults to experience severe COVID-19¹⁻⁹. Milder symptoms and asymptomatic presentation often mean less frequent care-seeking for these groups; thus, children and adolescents tend to be tested less frequently and cases may go unreported. Early reports suggested an age-dependent risk of severe disease with those under one year experiencing more severe disease^{6,10}, although several reviews show that neonates (first 28 days of life) have mild disease as compared to other paediatric patients¹¹⁻¹⁴. However, it is important to note that children under the age of one year and within the neonatal period (first 28 days after birth) have a higher risk

¹WHO Coronavirus (COVID-19) Dashboard | WHO Coronavirus (COVID-19) Dashboard with Vaccination Data; last accessed 06 September 2021.

of diseases which have overlapping presentation with COVID-19, such as pneumonia and malaria. Additionally, age disaggregation has not been systematically provided in the current literature and the results of these studies are context-specific such as timing within the pandemic and an emphasis on hospitalized patients.

Children and adolescents can experience prolonged clinical symptoms (known as post COVID-19 condition, or post-acute sequelae of SARS-CoV-2 infection), however, the frequency and characteristics of these are still under investigation¹⁵.

Additionally, a hyperinflammatory syndrome, referred to as paediatric inflammatory multisystem syndrome, temporally associated with SARS-CoV-2 (PIMS-TS) in Europe and multisystem inflammatory syndrome in children (MIS-C) in the United States of America, although rare, can occur, and complicates recovery from COVID-19¹⁶⁻¹⁹. The severity of disease in children and adolescents caused by SARS-CoV-2 variants of concern (VOC), in comparison with non-VOC lineages, remains under investigation.

Are children and adolescents less susceptible to SARS-CoV-2 infection than adults?

The risk of becoming infected with SARS-CoV-2 depends on a combination of susceptibility (host biological factors), biological properties of the virus, environmental factors associated with exposure type (going to work, or school etc.) and exposure intensity (level of community transmission and adherence to public health and social measures (PHSM)).

Multiple population-based SARS-CoV-2 seroprevalence and viral shedding studies have investigated whether children and adolescents are infected at the same rate as adults, but the results have been mixed, possibly because of the studies being conducted at different time points in the pandemic when populations were subjected to different levels of PHSM²⁰. Even so, we do know that children of all ages can become infected and can spread the virus to others.

Data on the global incidence of COVID-19 in adolescents suggests they test positive for SARS-CoV-2 at a higher proportion than children, however, seroprevalence surveys are needed to provide more information. Additionally, more detailed epidemiological information about the factors influencing susceptibility of children and adolescents to the new SARS-CoV-2 variants is urgently needed.

What about transmission of infection? Is there a difference between young children, older children and adolescents in transmitting SARS-CoV-2?

Outbreaks of COVID-19 have been identified in secondary schools, summer camps and day care centres, particularly when neither physical distancing nor masks were used to reduce risk²¹⁻²⁴. There is some preliminary evidence that children may be less infectious, than adolescents and adults, as measured by secondary attack rates²⁵.

Children and adolescents who become infected with SARS-CoV-2 shed the virus in their respiratory tract and may also shed virus in their faeces²⁶⁻²⁹. Among individuals who were positive for SARS-CoV-2 who were tested at the same time point after symptom onset, SARS-CoV-2 viral RNA shedding in the respiratory track appeared similar in children, adolescents and adults³⁰.

The relationship between age, viral load and transmission across the full symptom spectrum of SARS-CoV-2 infection has not been comprehensively investigated because people with no, or mild, symptoms are seldom tested systematically.

Thus, the relative transmissibility of SARS-CoV-2 at different ages remains uncertain, largely due to the challenges involved in disentangling the influences of biological, host, virus and environmental factors ³¹⁻³⁵.

Conclusions

Children and adolescents infected with SARS-CoV-2 generally present with milder symptoms of COVID-19 disease; although infection with the variants of SARS CoV-2, including the Delta variant, require more investigation to determine if this will remain the case. The risk of transmission to and from children and adolescents depends on contextual factors such as the level of community transmission and the measures implemented to control the virus, host factors in the child, as well as biological factors related to the virus itself. However, children and adolescents of all ages become infected and also transmit SARS-CoV-2 to others. Younger children may be less susceptible than older children and adolescents, but the precise role of children and adolescents in the overall transmission of SARS-CoV-2 still requires further investigation.

The use of public health and social measures (PHSM), including physical distancing, cleaning hands, coughing into a bent elbow or a tissue, adequate ventilation in indoor settings, and masks (for older children - see guidance below), should be consistently and appropriately implemented for all ages in schools, especially since children under the age of 12 years are generally not yet eligible for vaccination.

WHO regional overviews — Epidemiological week 6 – 12 September 2021

African Region

The African Region reported over 94 000 new cases and over 3000 new deaths, a 15% decrease and a 7% increase respectively as compared to the previous week. Although the regional case incidence has continued to decline for over two months, weekly incidence increased in 18 of 49 (37%) countries in the past week, including in Ethiopia and Nigeria. The highest numbers of new cases were reported from South Africa (40 220 new cases; 67.8 new cases per 100 000 population; a 29% decrease), Ethiopia (9269 new cases; 8.1 new cases per 100 000; a 10% increase), and Nigeria (5061 new cases; 2.5 new cases per 100 000; a 90% increase).

The highest numbers of new deaths were reported from South Africa (1590 new deaths; 2.7 new deaths per 100 000 population; a 6% decrease), Namibia (187 new deaths; 7.4 new deaths per 100 000), and Algeria (185 new deaths; 0.4 new deaths per 100 000; a 5% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported the largest proportional decrease in cases and the second largest proportional decrease in deaths this week, decreases of 17% and 9%, respectively, as compared to the previous week. However, the Region also reported the highest number of weekly cases and deaths as compared to other Regions, with notable increases observed in Cuba (22% increase) and Ecuador (72% increase) for cases, and Honduras (55% increase) and Haiti (50% increase) for deaths. The highest numbers of new cases were reported from the United States of America (1 034 836 new cases; 312.6 new cases per 100 000; a 20% decrease), accounting for 70% of all new cases reported in the Region this week, Brazil (118 790 new cases; 55.9 new cases per 100 000; a 22% decrease), and Mexico (88 938 new cases; 69.0 new cases per 100 000; a 5% decrease).

Similarly, the highest numbers of new deaths were reported from the United States of America (11 371 new deaths; 3.4 new deaths per 100 000; a 5% decrease), Mexico (4628 new deaths; 3.6 new deaths per 100 000; a 9% decrease), and Brazil (3176 new deaths; 1.5 new deaths per 100 000; a 27% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported a marked decrease (15%) in the number of new cases reported this week, with over 319 000 new cases. The Region reported a slight decrease (6%) in the number of new deaths reported, with over 6300 new deaths this week. These decreasing trends in cases and deaths reflect decreases in 13 of the 22 countries (59%) for cases and 15 out of 22 (68%) for deaths in the region this week. The highest numbers of new cases were reported from the Islamic Republic of Iran (172 030 new cases; 204.8 new cases per 100 000; a 17% decrease), Iraq (34 816 new cases; 86.6 new cases per 100 000; a 21% decrease), and Pakistan (25 819 new cases; 11.7 new cases per 100 000; a 4% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (3760 new deaths; 4.5 new deaths per 100 000; a 10% decrease), Pakistan (548 new deaths; <1 new deaths per 100 000; a 5% decrease), and Tunisia (497 new deaths; 4.2 new deaths per 100 000; a 47% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

Case incidence in the European Region decreased by 5% with just over 1.1 million new cases, while death incidence remained similar to that of the previous week with over 14 000 deaths. The highest numbers of new cases were reported from the United Kingdom (256 051 new cases; 377.2 new cases per 100 000; a 5% increase), Turkey (158 236 new cases; 187.6 new cases per 100 000; a 6% increase), and the Russian Federation (127 471 new cases; 87.3 new cases per 100 000; similar to the previous week's figures).

Similarly, the highest numbers of new deaths were reported from the Russian Federation (5549 new deaths; 3.8 new deaths per 100 000; similar to the previous week's figures), Turkey (1806 new deaths; 2.1 new deaths per 100 000; similar to the previous week's figures), and the United Kingdom (983 new deaths; 1.4 new deaths per 100 000; a 25% increase). These three countries accounted for almost half (49%) of new weekly cases and 59% of new weekly deaths reported in the Region.

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported substantial decreases in new cases and deaths with over 453 000 new cases and over 8900 new deaths, decreases of 16% and 20%, respectively as compared to the previous week. Overall, regional cases and deaths have declined consistently over the past month and a half. This week all countries in the Region reported a decrease in weekly cases and deaths as compared to last week, with a notable decrease reported in Indonesia (30% decrease) for cases and Bangladesh (33% decrease) for deaths. The highest numbers of new cases were reported from India (248 248 new cases; 18.0 new cases per 100 000; a 15% decrease), Thailand (101 639 new cases; 145.6 new cases per 100 000; a 5% decrease), and Indonesia (38 491 new cases; 14.1 new cases per 100 000; a 30% decrease).

Similarly, the highest numbers of new deaths were reported from Indonesia (3028 new deaths; 1.1 new deaths per 100 000; a 23% decrease), India (2122 new deaths; <1 new deaths per 100 000; a 21% decrease), and Thailand (1498 new deaths; 2.1 new deaths per 100 000; a 13% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Case incidence in the Western Pacific Region decreased by 8% with just over 487 000 new cases, while death incidence remained similar to that of the previous week with over 64 00 deaths. After reporting a continuous increase in cases since 21 June 2021, the Region has begun to show a declining trend in weekly cases over the past two weeks, mainly driven by declines in cases reported in Japan (46% decrease), Mongolia (46% decrease) and Fiji (45% decrease). However, the weekly deaths continue to show an increasing trend since 19 July 2021, with notable increases in weekly deaths reported for Guam (33% increase), and Malaysia (22% increase) this week.

The highest numbers of new cases were reported from the Philippines (144 991 new cases; 132.3 new cases per 100 000; a 16% increase), Malaysia (136 061 new cases; 420.4 new cases per 100 000; similar to the previous week's figures), and Viet Nam (90 179 new cases; 92.6 new cases per 100 000; similar to the previous week's figures). The highest numbers of new deaths were reported from Malaysia (2536 new deaths; 7.8 new deaths per 100 000; a 22% increase), Viet Nam (2225 new deaths; 2.3 new deaths per 100 000; a 7% decrease), and the Philippines (916 new deaths; <1 new deaths per 100 000; a 13% decrease).

Updates from the [Western Pacific Region](#)

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

from official sources.

ation become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community).

Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

*** Alpha was excluded for Comoros this week based on further information.

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 56, published 7 September 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the COVID-19 Weekly Operational Update](#)

Global overview

Data as of 5 September 2021

Globally, the number of new cases reported this week remained similar to that of the previous week. With over 4.4 million new cases reported this week (30 August-5 September; Figure 1), the global incidence of COVID-19 cases has remained stable over the past month. In the past week, all regions reported either a decline (Regions of Africa, South-East Asia, and the Eastern Mediterranean) or a similar trend in new reported cases, as compared to previous week (Regions of Europe and the Western Pacific); the Region of the Americas reported a 19% increase.

The number of deaths reported globally this week also remained similar to the previous week, with just under 68 000 new deaths reported. The incidence of new deaths declined in all regions apart from the Region of the Americas and Europe where deaths increased by 17% and 20%, respectively. Regionally, the largest proportionate decreases in new deaths this week were observed in the South-East Asia (21% decrease) and African (26% decrease) regions, while the regions of the Western Pacific (8% decrease) and the Eastern Mediterranean (14% decrease) also reported notable declines, as compared to the previous week. The cumulative number of cases reported globally is now just over 220 million and the cumulative number of deaths is over 4.5 million.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 5 September 2021**

**See Annex 2: Data, table and figure notes

The Regions reporting the highest weekly case and deaths incidence rates per 100 000 population remain the same as last week: the Regions of the Americas (172.4 new cases per 100 000 population; 2.5 deaths per 100 000 population) and Europe (122.8 new cases per 100 000 population; 1.6 deaths per 100 000 population).

The highest numbers of new cases were reported from the United States of America (1 297 399 new cases; 38% increase), India (293 643 new cases; 8% increase), the United Kingdom (243 125 new cases; similar to the previous week), the Islamic Republic of Iran (208 089 new cases; 18% decrease), and Brazil (152 154 new cases; 13% decrease).

Globally, cases of the Alpha variant have been reported in 194 countries (one new country since last week), territories or areas (hereafter countries), while 141 countries (no new countries) have reported cases of the Beta variant; 92 countries (one new country) have reported cases of the Gamma variant; and 174 countries (four new countries) have reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 5 September 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 763 048 (39%)	19%	84 995 058 (39%)	26 028 (38%)	17%	2 120 533 (47%)
Europe	1 146 065 (26%)	-4%	66 029 959 (30%)	14 883 (22%)	20%	1 282 565 (28%)
South-East Asia	543 013 (12%)	-9%	41 662 330 (19%)	11 116 (16%)	-21%	652 990 (14%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

Updates on VOCs and VOIs, and a list of Alerts for Further Monitoring, are available on the [WHO Tracking SARS-CoV-2 Variants website](#).

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of these COVID-19 Weekly Epidemiological Updates. Since the last detailed update on 24 August, new evidence has been published on the phenotypic characteristics of VOCs.

A retrospective cohort study, available in preprint, of RT-PCR SARS-CoV-2 positive individuals was conducted using healthcare datasets in the provinces of Ontario and Alberta, Canada, which were the most affected provinces during the resurgence of cases in Canada from February to May 2021. During this time, the 30-day outcomes of those infected with VOCs (n=37 902), of which 91% (34 658/37 902) were infected with the Alpha variant, showed a higher risk of death [adjusted Odds Ratio (aOR) of 1.34 (95% Confidence Interval 1.29-1.39) in Ontario and 1.53 (95% CI: 1.41-1.65) in Alberta] and hospitalization [aOR 1.57 (95% CI: 1.47-1.69) in Ontario and aOR 1.88 (95% CI: 1.74-2.02) in Alberta]] as compared to those infected with non-VOCs.¹

In a prospective clinical cohort study of hospitalized and community cases (n=1475) conducted between 1 November 2020 to 30 January 2021 in Scotland as part of a larger study in the United Kingdom, and published as a preprint, infection with the Alpha variant was associated with increased clinical severity [cumulative OR 1.40 (95% CI: 1.02-1.93)] as compared to non-Alpha SARS-CoV-2 infection. Additionally, the viral load of samples positive for the Alpha variant, as measured by the cycle threshold (Ct) value, was lower than that of non-Alpha samples [mean change in Ct: -2.46 (95% CI -4.22, -0.70)], where lower Ct value indicates higher viral load of specimens.²

A recent study from China, published as a preprint, found a higher viral load and higher risk of pre-symptomatic transmission in patients infected with the Delta variant when compared to those infected with non-VOC SARS-CoV-2.³ The study identified 167 patients infected with the Delta variant in an outbreak in Guangdong. The mean estimates of the latent period and the incubation period were 4.0 and 5.8 days, respectively. A relatively higher viral load was observed in Delta cases than in the 49 non-VOC SARS-CoV-2

infections. The study also found the secondary attack rate among close contacts of Delta cases was 1.4%, and 73.9% (95% CI: 67.2%- 81.3%) of the transmissions occurred before onset of symptoms. Index cases without vaccination (OR: 2.84, 95% CI: 1.19, 8.45) or with a single dose of vaccination (OR: 6.02, 95% confidence interval: 2.45, 18.16) were more likely to transmit infection to their contacts than those who had received two doses of vaccination.³ Although this study provides insight into differences in the incubation period and secondary transmission of the Delta variant, these are preliminary findings specific to one outbreak and further studies will aid in understanding how these findings can be generalized to other contexts.

A large national cohort study from the United Kingdom found higher risk of admission to hospital or emergency care for COVID-19 patients infected with the Delta variant as compared to those infected with the Alpha variant.⁴ In this study, 2.3% (196/8682) patients infected with the Delta variant versus 2.2% (764/34 656) patients infected with the Alpha variant were admitted to hospital within 14 days after the first positive specimen was collected (adjusted hazard ratio [HR] 2.26 [95% CI 1.32–3.89]). Additionally, the HR for hospital admission with the addition of attendance to emergency care was higher in patients infected with the Delta variant within 14 days (5.7%) than those infected with the Alpha variant (4.2%) (adjusted HR 1.45 [1.08–1.95]).⁴ Nearly three quarters (74%) of all individuals, across both groups included in the study, were unvaccinated. Overall, these findings suggest that outbreaks of the Delta variant may lead to a greater burden on health-care services than the Alpha variant, a burden which may be even greater in largely unvaccinated populations.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility ⁵	Increased transmissibility ^{6,7}	Increased transmissibility ^{7,8}	Increased transmissibility and secondary attack rate ^{7,9}
Disease severity	Increased risk of hospitalization ¹⁰ , possible increased risk of severity and mortality ^{11,2}	Not confirmed, possible increased risk of in-hospital mortality ¹²	Not confirmed, possible increased risk of hospitalization ¹³	Increased risk of hospitalization ¹⁴
Risk of reinfection	Neutralizing activity retained ¹⁵ , risk of reinfection remains similar ¹⁶	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ¹⁷	Moderate reduction in neutralizing activity reported ¹⁸	Reduction in neutralizing activity reported ^{19–21}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF); no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed ²²	No impact on RT-PCR or Ag RDTs observed ²¹	None reported to date	None reported to date

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

VE refers to vaccine effectiveness and vaccine efficacy

Summary of VE*: indicates the general conclusions but only for the vaccines evaluated against the specific variant

Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used.

“Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the VIEW-hub Resources page (<https://view-hub.org/resources>). For individual vaccine effectiveness studies, see ‘COVID-19 Vaccine Effectiveness Results Summary’, reference numbers noted with a ‘#’. For a list of all neutralization studies, see ‘COVID-19 Vaccine Neutralization Studies Table’.

References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table and are included in the reference section below.

Since the [24 August update](#), three studies have been published that have assessed vaccine effectiveness against SARS-CoV-2 variants of concern.

A retrospective cohort study (preprint) from the United States of America evaluated the effectiveness of the Pfizer BioNTech-Comirnaty vaccine against documented infection and hospitalization due to the Delta variant seven or more days after receiving the second dose, among persons ≥ 12 years of age in a large healthcare system.³⁰ VE against Delta infection was lower than that against infection due to non-Delta variants [75%, (95% CI: 71-78%) vs. 91% (95% CI: 88-92%)]. The decreased VE for Delta infection is likely explained by multiple factors including but not limited to confounding effect of waning VE and inherent properties of Delta variants that influence immune escape. Given that the Delta variant became dominant in June, the timing of most Delta infections included in this study likely occurred after longer intervals post-vaccination as compared to that of non-Delta infections. When stratifying by time since vaccination, VE against infection due to Delta was high (93%) one month after full vaccination but dropped to 53% four or more months after full vaccination. While a decrease in VE was also observed for non-Delta variants as the time since full vaccination increased, this decrease was less pronounced (97% at one month vs. 67% at four months post vaccination), which, although not statistically significantly different from the findings for Delta, could suggest that waning may be more pronounced for Delta than other variants. VE against hospitalization due to Delta remained high at 90% (95% CI: 89-92%) and was comparable to the VE against hospitalization due to non-Delta variants of 95% (95% CI: 90-98%).

A second retrospective cohort study (preprint) of over 9 million individuals ≥ 16 years of age in Israel assessed the effectiveness of Pfizer BioNTech-Comirnaty in preventing infection and severe disease during the month of July when Delta was the predominant variant.³¹ The study evaluated the VE among persons vaccinated more recently compared to those vaccinated earlier. For persons fully vaccinated two months prior, VE against infection ranged from 73%-80% by age group, whereas VE for persons vaccinated six months prior ranged from 50-58% by age group. For all age groups, VE against infection decreased with increasing age at time of vaccination. However, consistent with the above study from the United States of America, investigators found that VE against severe disease remained high for persons 40 years and older vaccinated six months prior. (VE of 94% for persons 40-59 years and 86% for persons ≥ 60 years of age). Of note, this study did not compare VE for Delta against other variants, so the relative VE by variant was not presented.

A third study (preprint) used a test-negative design to evaluate the effectiveness of Pfizer BioNTech-Comirnaty against infection and severe disease due to Alpha, Beta, and Delta variants, separately, among individuals ≥ 16 years in Qatar.³² VE against infection due to Alpha, Beta, and Delta five to nine weeks post second dose was 82.2% (95% CI: 72.1-89.0%), 52.7% (95% CI: 40.3-62.7%), and 72.0% (95% CI: 60.5-80.5%), respectively. VE against infection showed a general trend of decreasing VE after five to nine weeks post second dose for all variants through to ≥ 25 weeks post second dose, with 0% VE for the Alpha and Delta variants beyond 20 weeks. VE against infection due to each of the variants was lower than that observed in other studies, although the Qatar study was different in that most infections were asymptomatic. VE against severe, critical and fatal disease at five to nine weeks post second dose was high for all variants: 100.0% (95% CI: 0.0-100%), 94.6% (95% CI: 63.5-99.9%), and 100% (95% CI: 74.3-100%) for the Alpha, Beta, and Delta variants, respectively. VE against hospitalization and at later time points after vaccination remained high, but it is not possible to interpret the waning VE against severe disease because there were very small numbers of subjects and wide confidence intervals for these later time points.

In addition to the above studies, two recent studies from Israel evaluated the short-term relative effectiveness of a third dose of Pfizer BioNTech-Comirnaty in preventing infection and severe disease compared to those who received two doses of vaccine, during the past month when Delta was the dominant circulating strain.^{33,34} One study found that a third dose of the vaccine decreased the relative risk of infection

and of severe disease ≥ 12 or more days post vaccination by 11.4- and 15.5-fold, respectively compared to persons receiving two doses of the vaccine. In a second study, 79% (95% CI: 72-84%) of infections 14-20 days post vaccination were estimated to have been prevented by a third dose of the vaccine compared to persons receiving two doses. Of note, neither of these studies provide the absolute VE compared to an unvaccinated group, as was done in the previously mentioned studies of fully vaccinated persons.

Similar to the studies included in the 24 August update, these studies provide additional evidence for continued high VE of Pfizer BioNTech-Comirnaty against severe COVID-19 due to the Delta variant. There is some evidence from multiple studies that VE against SARS-CoV-2 infection and non-severe disease may be reduced with Delta. However, it is challenging to separate the effect of Delta from the effect of potential waning immunity, as Delta circulation in most countries became dominant several months after vaccine introduction. In addition, differential risk of exposure profiles between vaccinated and unvaccinated populations, as well as early versus late vaccines, increasing levels of natural immunity in the unvaccinated population over time, or other potential confounding factors, complicate interpretation of VE estimates over time. Furthermore, the study from Qatar provides additional evidence of reduced Pfizer BioNTech-Comirnaty effectiveness against infection due to Beta, consistent with previous studies. Additional studies, over longer time periods and in different settings are needed to further support these initial findings.

Additional notes on VOC impacts on vaccines

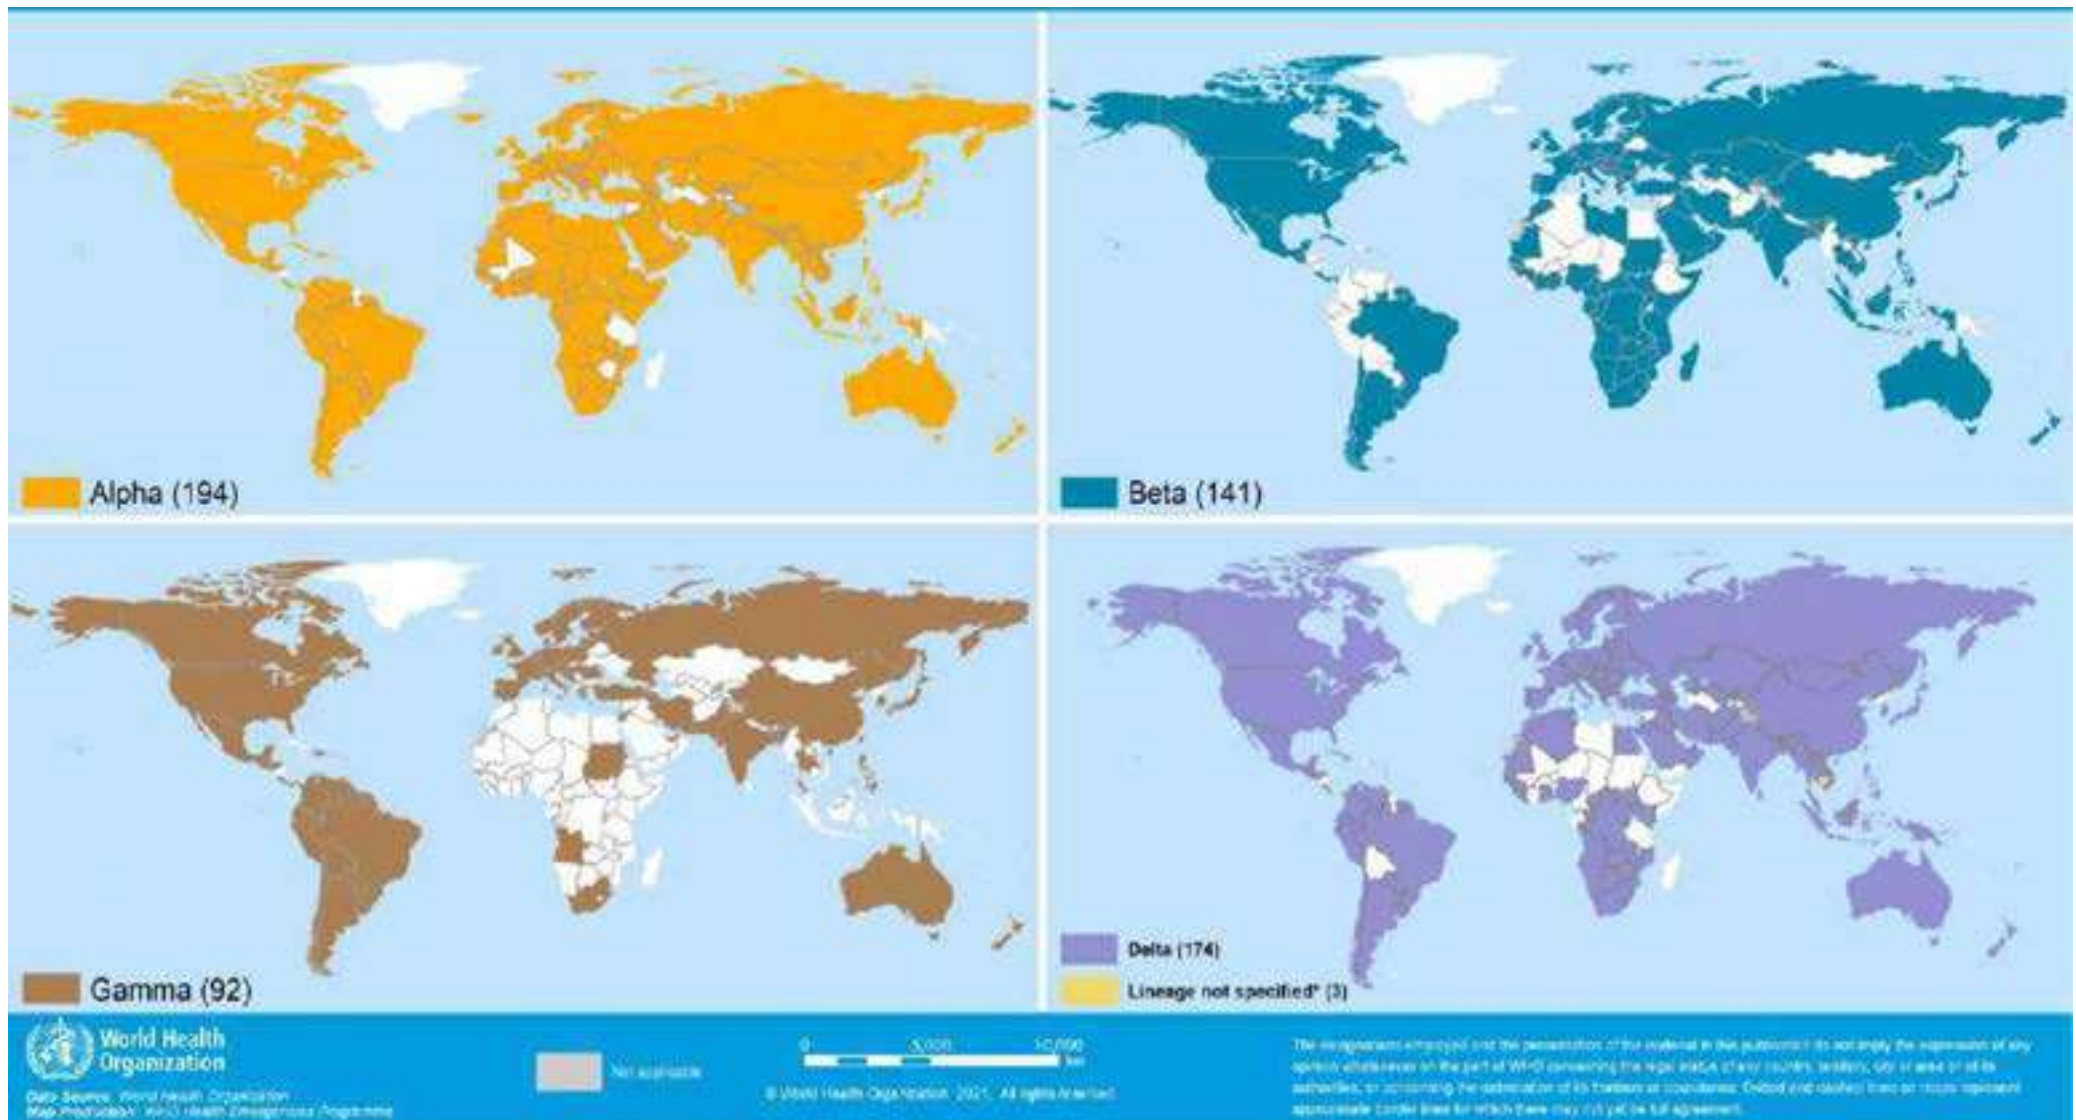

- Studies presenting VOC-specific vaccine efficacy or effectiveness (VE) estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for severe disease (phase 3 RCT efficacy estimates against severe disease are used as comparator since a within study comparator is unavailable) and for infection (when phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.
- Some VE estimates may not be included in the table above when it is not possible to tease out the effect of waning from the effect of variants on vaccine performance.

Table 3 presents the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to VE in non-VOC settings. Of note, reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of $\sim 85\%$. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection, as is the case for AstraZeneca-Vaxzevria.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 7 September 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews — Epidemiological week 30 Aug–5 Sep 2021

African Region

The African Region continued to report substantial declines in incidence of both cases and deaths. This week the Region reported over 110 000 new cases and over 2800 new deaths, decreases of 25% and 26%, respectively, as compared to the previous week. These declining trends for the Region's third wave are encouraging, and largely driven by continued declines in South Africa. Nonetheless, several countries continued to report increasing trends in cases (> 30%) this week while mortality continued to increase, albeit at a lower proportion (>10%) in five countries. The highest numbers of new cases were reported from South Africa (56 823 new cases; 95.8 new cases per 100 000 population; a 26% decrease), Ethiopia (8391 new cases; 7.3 new cases per 100 000; a 17% decrease), and Botswana (5524 new cases; 234.9 new cases per 100 000; a 25% decrease).

The highest numbers of new deaths were reported from South Africa (1700 new deaths; 2.9 new deaths per 100 000 population; a 23% decrease), Algeria (194 new deaths; <1 new death per 100 000; similar to the previous week), and Nigeria (127 new deaths; <1 new death per 100 000; a 26% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported marked increases in the number of cases and deaths in the past week. With over 1.7 million new cases and over 26 000 new deaths, increases of 19% and 17%, respectively. These are the largest regional proportionate increases in cases at the regional level as compared to the previous week. The highest numbers of new cases were reported from the United States of America (1 297 399 new cases; 392.0 new cases per 100 000; a 38% increase), Brazil (152 154 new cases; 71.6 new cases per 100 000; a 13% decrease), and Mexico (93 977 new cases; 72.9 new cases per 100 000; an 18% decrease).

The highest numbers of new deaths were reported from the United States of America (11 946 new deaths; 3.6 new deaths per 100 000; a 63% increase), Mexico (5071 new deaths; 3.9 new deaths per 100 000; similar to the previous week), and Brazil (4344 new deaths; 2.0 new deaths per 100 000; a 10% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 377 000 new cases and over 6700 new deaths, decreases of 16% and 14%, respectively, as compared to the previous week. The downward trend in the number of new cases reflects the decrease in case incidence from the top three countries reporting the highest numbers in the Region; the Islamic Republic of Iran (208 089 new cases; 247.7 new cases per 100 000; an 18% decrease), Iraq (44 043 new cases; 109.5 new cases per 100 000; a 10% decrease), and Morocco (31 510 new cases; 85.4 new cases per 100 000; a 27% decrease). These three countries accounted for over 75% of all new cases in the Eastern Mediterranean. However, six of 22 countries in the Region, including Djibouti, Egypt, occupied Palestinian territory, Oman, Syrian Arab Republic and Yemen reported increases in case incidence.

The highest numbers of new deaths were reported from the Islamic Republic of Iran (4163 new deaths; 5.0 new deaths per 100 000; an 8% decrease), Morocco (632 new deaths; 1.7 new deaths per 100 000; an 8% decrease), and Pakistan (579 new deaths; 0.3 new deaths per 100 000; a 16% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

While the European Region reported a number of new cases similar to that of the past week, with over 1.1 million new cases, the number of deaths increased by 20% with over 14 000 new deaths as compared to the previous week. Almost half (29/61) of the countries reported an increase in death incidence compared to last week. However, in a few countries in the Region where relatively high vaccination coverage and high case incidence were reported, death incidence was relatively low compared to that of countries with low vaccination coverage. The highest numbers of new cases were reported from the United Kingdom (243 125 new cases; 358.1 new cases per 100 000; similar to the previous week), Turkey (149 114 new cases; 176.8 new cases per 100 000; a 13% increase), and the Russian Federation (129 772 new cases; 88.9 new cases per 100 000; similar to the previous week).

The highest numbers of new deaths were reported from the Russian Federation (5563 new deaths; 3.8 new deaths per 100 000; similar to the previous week), Turkey (1879 new deaths; 2.2 new deaths per 100 000; a 15% increase), and Kazakhstan (1768 new deaths; 9.4 new deaths per 100 000).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 543 000 new cases and over 11 000 new deaths, decreases of 9% and 21%, respectively, as compared to the previous week. Despite the overall regional decline in case incidence, India, Myanmar and the Maldives reported increases in the number of cases of 8%, 24% and 43%, respectively, as compared to the previous week. The highest numbers of new cases were reported from India (293 643 new cases; 21.3 new cases per 100 000; an 8% increase), Thailand (106 443 new cases; 152.5 new cases per 100 000; a 15% decrease), and Indonesia (55 189 new cases; 20.2 new cases per 100 000; a 42% decrease).

All countries except for Sri Lanka and Timor-Leste reported decreases in weekly mortality by more than 5%. The highest numbers of new deaths were reported from Indonesia (3938 new deaths; 1.4 new deaths per 100 000; a 29% decrease), India (2703 new deaths; <1 new deaths per 100 000; a 22% decrease), and Thailand (1712 new deaths; 2.5 new deaths per 100 000; a 6% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 531 000 new cases, a similar number as the previous week, and over 6200 new deaths, an 8% decrease compared to the previous week. Although the absolute numbers of cases and deaths remain very high, this is the first week in over two months in which declining trends in the number of deaths were reported. The highest numbers of new cases were reported from Malaysia (138 929 new cases; 429.2 new cases per 100 000; an 8% decrease), the Philippines (125 470 new cases; 114.5 new cases per 100 000; a 12% increase), and Japan (122 628 new cases; 97.0 new cases per 100 000; a 22% decrease).

The highest numbers of new deaths were reported from Viet Nam (2388 new deaths; 2.5 new deaths per 100 000; a 17% decrease), Malaysia (2081 new deaths; 6.4 new deaths per 100 000; a 12% increase), and the Philippines (1054 new deaths; 1.0 new deaths per 100 000; a 25% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) (WOU) is a report provided by the COVID-19 Strategic preparedness and response plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this week's edition of the COVID-19 Weekly Operational Update, published on 6 September, highlights of country-level actions and WHO support to countries include:

- Shipment of medical supplies to Viet Nam
- Engagement of the African Regional Monitoring of Vaccine Effectiveness (AFRO-MoVE) in 17 countries
- Scale-up capacity for real-time PCR testing for SARS-CoV-2 and biosafety in Montenegro at the subnational level
- Risk Communications and Community Engagement support hotline in Thailand
- Civil Society engagement in North-West Syria
- Updates on WHO's Early AI-Powered Social Listening Tool (EARS) to support country infodemic management
- Inauguration of the WHO Hub for Pandemic and Epidemic Intelligence in Berlin
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

For more information, see the [Weekly operational update on COVID-19](#)

Annex

- COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

from official sources.

ation become available.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 55, published 31 August 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Summary of the Weekly Operational Update](#)

Global overview

Data as of 29 August 2021

With just under 4.4 million new cases reported this week (23-29 August), the number of new cases reported globally remains similar to the previous week after having increased for nearly two months (Figure 1). In the past week, all regions reported either a decline (Regions of Africa and the Americas) or a similar trend (Europe, South-East Asia and Eastern Mediterranean Regions) in new cases, except for the Western Pacific Region which reported a 7% increase as compared to previous week.

The number of deaths reported globally this week was also similar to last week, with just over 67 000 new deaths reported. The Eastern Mediterranean and Western Pacific Regions reported an increase in the number of weekly deaths, 9% and 16% respectively, while the South-East Asia Region reported the largest decrease (20%). The numbers of deaths reported in the Regions of Africa, Europe and the Americas were similar to last week. The cumulative number of cases reported globally is now nearly 216 million and the cumulative number of deaths is just under 4.5 million.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 29 August 2021**

**See [Annex 2: Data, table and figure notes](#)

The Regions reporting the highest weekly incidence rates per 100 000 population of cases and of deaths remain the same as last week: the Regions of the Americas (144.9 new cases per 100 000 population; 2.2 deaths per 100 000 population) and Europe (125.7 new cases per 100 000 population; 1.3 deaths per 100 000 population). The Eastern Mediterranean Region also reported a high incidence of weekly deaths (1.1 per 100 000 population).

The highest numbers of new cases were reported from the United States of America (938 014 new cases; 8% decrease), India (270 796 new cases; 17% increase), the Islamic Republic of Iran (254 753 new cases; similar to the previous week), the United Kingdom (237 556 new cases; 8% increase), and Brazil (175 807 new cases; 16% decrease).

Globally, cases of the Alpha variant have been reported in 193 countries (one new country since last week), territories or areas (hereafter countries), while 141 countries (no new countries) have reported cases of the Beta variant; 91 countries (five new countries) have reported cases of the Gamma variant; and 170 countries (seven new countries) have reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 29 August 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 481 995 (34%)	-9%	83 231 838 (39%)	22 259 (33%)	1%	2 094 503 (47%)
Europe	1 172 461 (27%)	-1%	64 856 816 (30%)	12 584 (19%)	4%	1 267 494 (28%)
South-East Asia	596 456 (14%)	-3%	41 119 317 (19%)	14 010 (21%)	-20%	641 874 (14%)
Eastern Mediterranean	443 703 (10%)	-2%	14 498 768 (7%)	7 831 (12%)	9%	264 425 (6%)
Western Pacific	553 344 (13%)	7%	6 399 247 (3%)	6 835 (10%)	16%	88 168 (2%)
Africa	147 789 (3%)	-7%	5 608 074 (3%)	3 869 (6%)	-3%	134 276 (3%)
Global	4 395 748 (100%)	-4%	215 714 824 (100%)	67 388 (100%)	-2%	4 490 753 (100%)

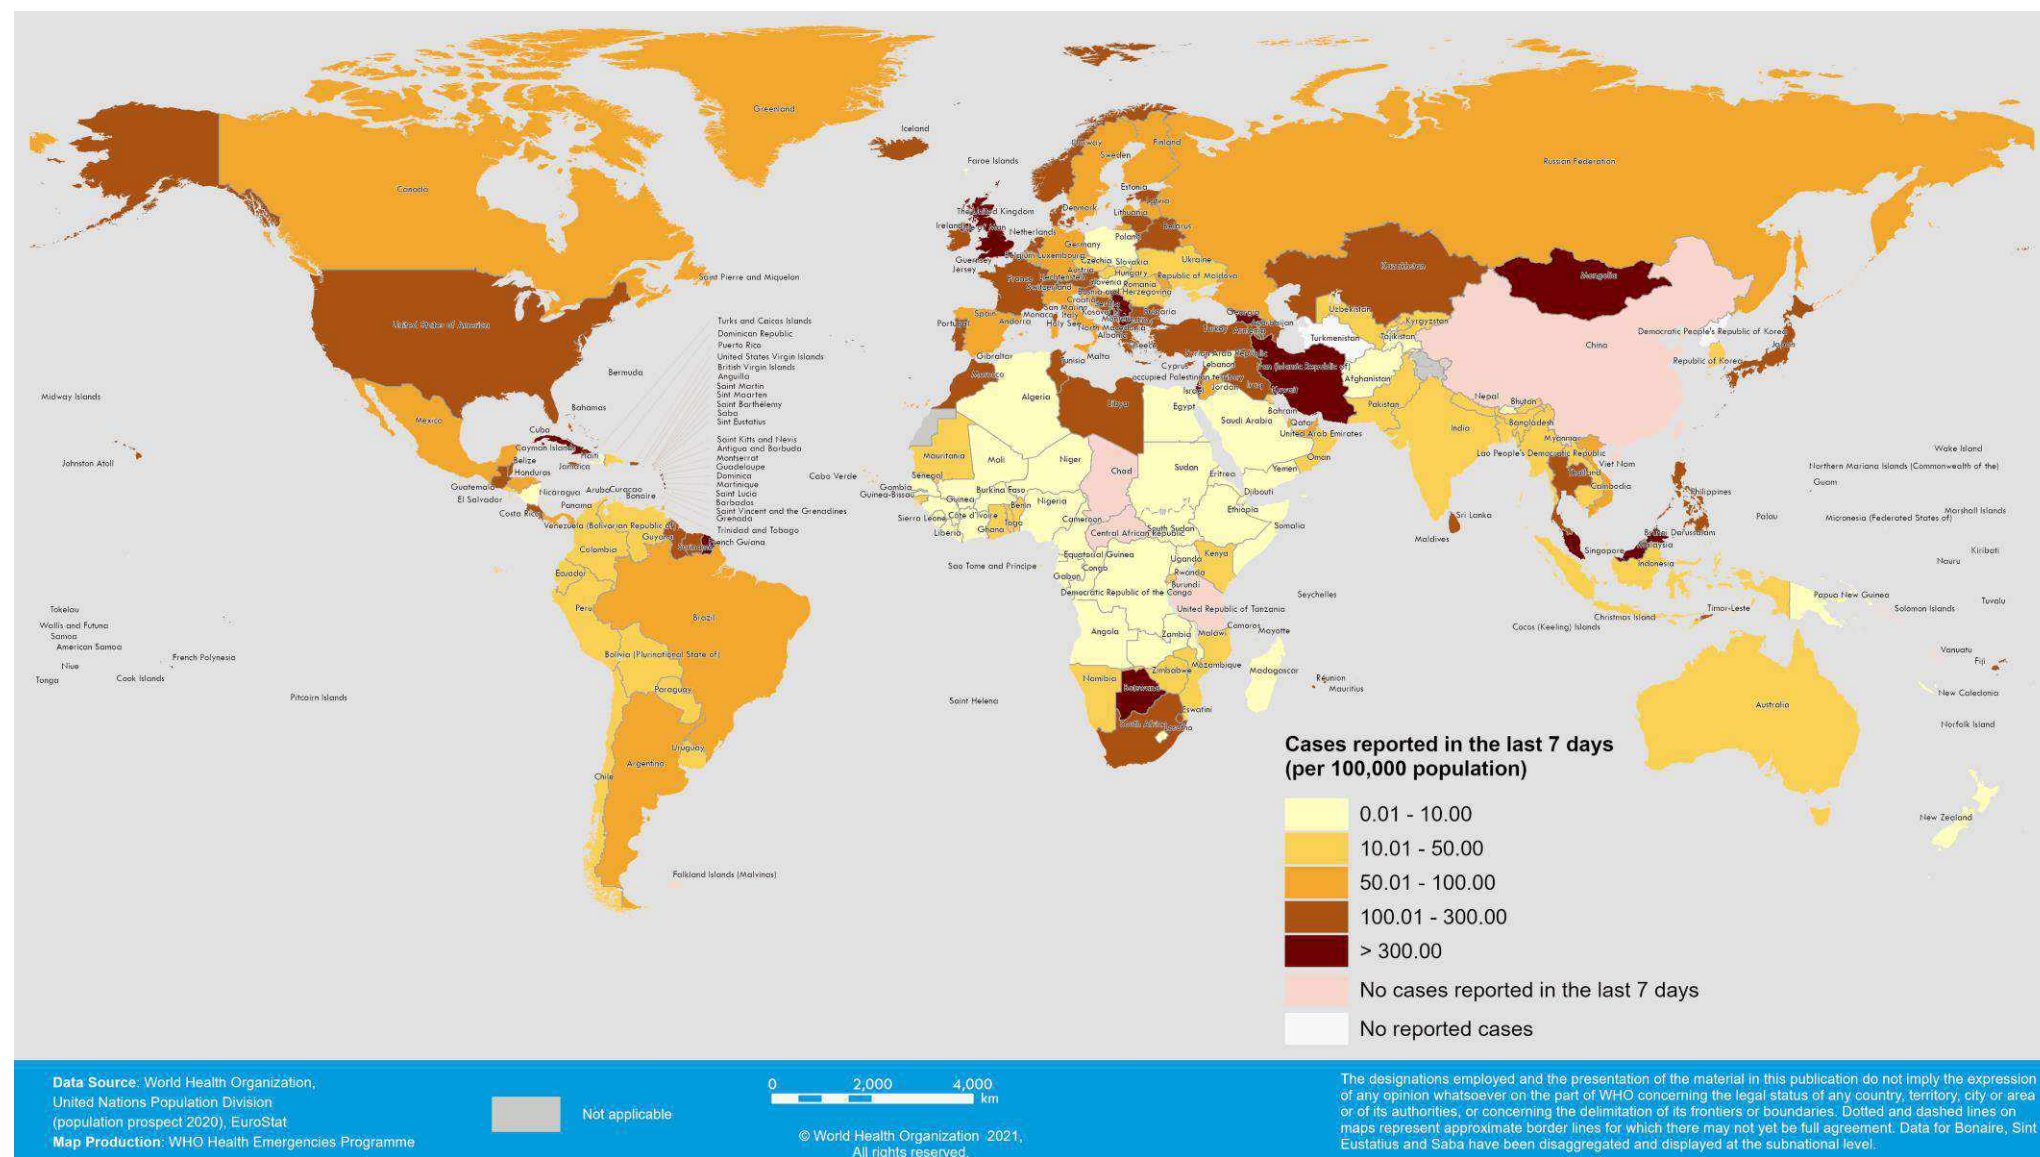

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health.

As these risks evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website).

National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on thorough risk assessments conducted systematically and routinely.

Updates to the variant classifications

As the global public health risks posed by specific SARS-CoV-2 variants become better understood, WHO will continue to update the list of global VOIs and VOCs to support the setting of priorities for surveillance and research, and ultimately to guide response strategies. These updates reflect virus evolution and the emergence of new variants, changing epidemiology, as well as our evolving understanding of the phenotypic impacts of variants as new evidence becomes available. A previously designated Alert for further monitoring which subsequently meets the [WHO working definition of a Variant of Interest \(VOI\) or Variant of Concern \(VOC\)](#) can be reclassified.

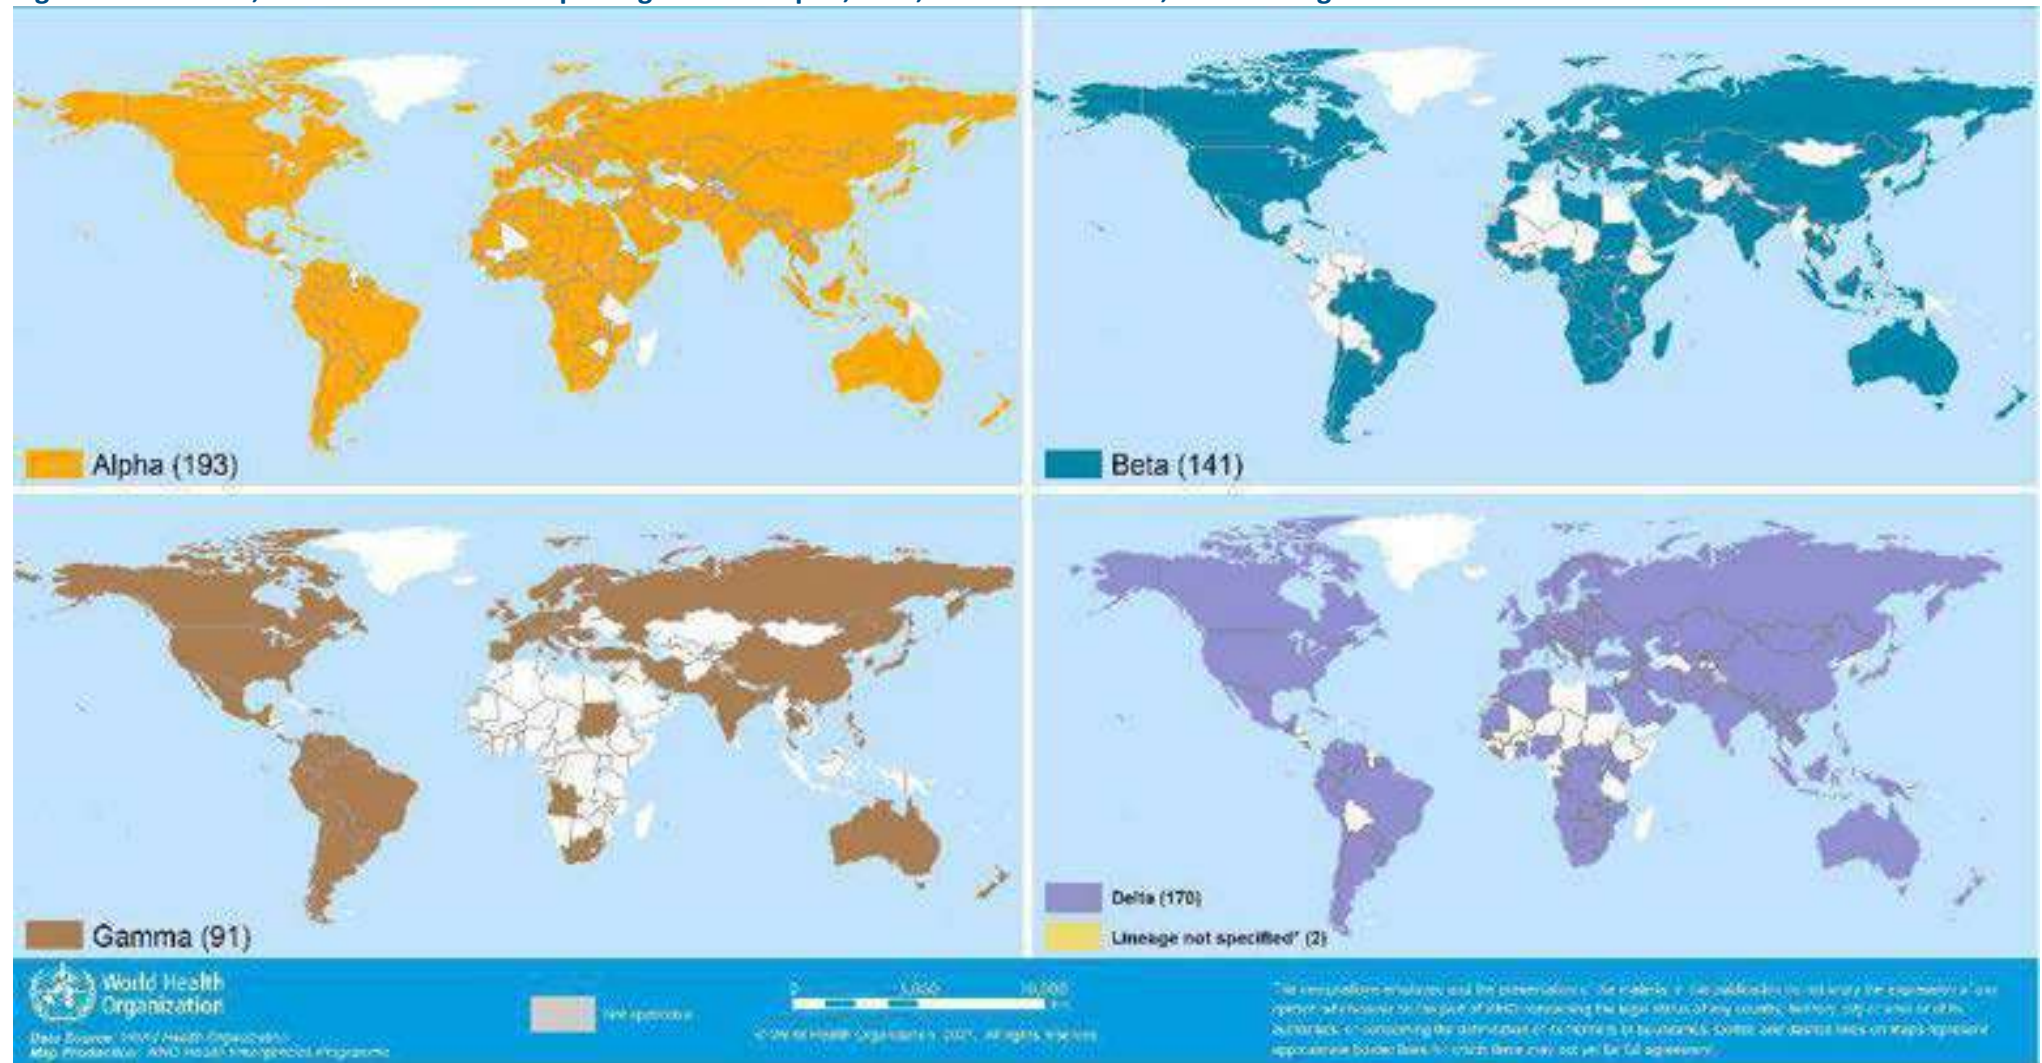

Based on the latest round of assessments, B.1.621 was classified as a VOI on 30 August 2021 and given the WHO label “Mu”. This includes the descendent Pango lineage B.1.621.1. This variant is known as 21H in Nextstrain nomenclature. The Mu variant has a constellation of mutations that indicate potential properties of immune escape. Preliminary data presented to the Virus Evolution Working Group show a reduction in neutralization capacity of convalescent and vaccinee sera similar to that seen for the Beta variant, but this needs to be confirmed by further studies.

Since its first identification in Colombia in January 2021, there have been a few sporadic reports of cases of the Mu variant and some larger outbreaks have been reported from other countries in South America and in Europe. As of 29 August, over 4500 sequences (3794 sequences of B.1.621 and 856 sequences of B.1.621.1) have been uploaded to [GISAID](#) from 39 countries. Although the global prevalence of the Mu variant among sequenced cases has declined and is currently below 0.1%, the prevalence in Colombia (39%) and Ecuador (13%) has consistently increased. The reported prevalence should be interpreted with due consideration of sequencing capacities and timeliness of sharing of sequences, both of which vary between countries. More studies are required to understand the phenotypic and clinical characteristics of this variant. The epidemiology of the Mu variant in South America, particularly with the co-circulation of the Delta variant, will be monitored for changes.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 31 August 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews — Epidemiological week 23 – 29 Aug 2021

African Region

This week the African Region reported over 147 000 new cases, a 7% decrease as compared to the previous week as the Region continued its decreasing trend. In the past week, two countries, South Africa and Ethiopia, accounted for over half (59%) of all the new cases reported in the Region. Over 3800 new deaths were reported in the Region this week, a similar number to that reported during the previous week. However, there are still a number of countries reporting worrying mortality trends; in the past week, eight countries reported increases of over 50% in weekly deaths. The highest numbers of new cases were reported from South Africa (76 966 new cases; 129.8 new cases per 100 000 population; a 9% decrease), Ethiopia (10 058 new cases; 8.7 new cases per 100 000; a 61% increase), and Botswana (7332 new cases; 311.8 new cases per 100 000; a 24% decrease).

The highest numbers of new deaths were reported from South Africa (2210 new deaths; 3.7 new deaths per 100 000 population; a 7% decrease), Kenya (227 new deaths; <1 new death per 100 000; a 53% increase), and Algeria (195 new deaths; 0.4 new deaths per 100 000; an 11% decrease).

Updates from the [African Region](#)

Region of the Americas

Despite reporting the largest proportional decrease (9%) in cases this week, the Region of the Americas reported over 1.4 million new cases, the largest number of cases reported globally; the United States of America continued to report the largest number of cases in the Region accounting for 63% of all new cases reported this week. Notable increases in cases were also observed in Canada (28% increase) and Guatemala (23% increase) this week. The Region reported over 22 000 new deaths this week, similar to the number reported during the previous week. The highest numbers of new cases were reported from the United States of America (938 014 new cases; 283.4 new cases per 100 000; an 8% decrease), Brazil (175 807 new cases; 82.7 new cases per 100 000; a 16% decrease), and Mexico (114 209 new cases; 88.6 new cases per 100 000; an 11% decrease).

The highest numbers of new deaths were reported from the United States of America (7323 new deaths; 2.2 new deaths per 100 000; a 9% increase), Mexico (5070 new deaths; 3.9 new deaths per 100 000; a 9% increase), and Brazil (4815 new deaths; 2.3 new deaths per 100 000; a 15% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

While the number of new cases reported in the Eastern Mediterranean Region this week remained similar to the previous week with over 443 000 new cases reported, the Region reported over 7800 new deaths, a 9% increase compared to the previous week. This increasing trend in mortality can be attributed to the number of deaths increasing in 9 of the 22 countries (41%) in the region this week. The highest numbers of new cases were reported from the Islamic Republic of Iran (254 753 new cases; 303.3 new cases per 100 000; similar to the previous week), Iraq (48 897 new cases; 121.6 new cases per 100 000; similar to the previous week), and Morocco (43 244 new cases; 117.2 new cases per 100 000; a 20% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (4547 new deaths; 5.4 new deaths per 100 000; a 10% increase), Tunisia (760 new deaths; 6.4 new deaths per 100 000; a 7% increase), and Pakistan (687 new deaths; <1 new death per 100 000; a 35% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

Overall, in the European Region the numbers of new cases and deaths reported this week remained similar to the previous week, with over 1.1 million new cases and over 12 000 new deaths. Although the number of new weekly cases seem to be plateauing, the number of new deaths, while showing signs of slowing, has continued to increase in many countries in the Region, and should continue to be closely monitored. The highest numbers of new cases were reported from the United Kingdom (237 556 new cases; 349.9 new cases per 100 000; an 8% increase), the Russian Federation (135 740 new cases; 93.0 new cases per 100 000; a 7% decrease), and Turkey (132 508 new cases; 157.1 new cases per 100 000; similar to the previous week).

The highest numbers of new deaths were reported from the Russian Federation (5593 new deaths; 3.8 new deaths per 100 000; similar to the previous week), Turkey (1631 new deaths; 1.9 new deaths per 100 000; a 23% increase), and the United Kingdom (785 new deaths; 1.2 new deaths per 100 000; a 13% increase).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported a relatively similar case incidence as compared to the previous week with over 596 000 new cases. Despite a regional decrease in deaths, three countries reported increases of over 15% this week: Timor-Leste (32%), Sri Lanka (19%) and India (17%). The Region reported over 14 000 new deaths, a 20% decrease compared to the previous week, largely due to 60% (6/10) of countries in the Region reporting decreases in weekly mortality during the past week. The highest numbers of new cases were reported from India (270 796 new cases; 19.6 new cases per 100 000; a 17% increase), Thailand (124 796 new cases; 178.8 new cases per 100 000; a 12% decrease), and Indonesia (94 375 new cases; 34.5 new cases per 100 000; a 25% decrease).

The highest numbers of new deaths were reported from Indonesia (5551 new deaths; 2.0 new deaths per 100 000; a 37% decrease), India (3463 new deaths; <1 new death per 100 000; a 10% increase), and Thailand (1823 new deaths; 2.6 new deaths per 100 000; similar to the previous week).

Updates from the [South-East Asia Region](#)

Western Pacific Region

For the past two months, the Western Pacific Region has reported an increasing trend in the numbers of weekly cases and deaths. In the past week, the Region reported over 553 000 new cases and over 6800 new deaths, increases of 7% and 16%, respectively, as compared to the previous week. Nearly half (48%) of all countries in the Region reported increases this week. The Western Pacific Region reported the highest proportionate increase in new deaths this week, an increase driven by substantial increases in case incidence in French Polynesia (86%), Japan (53%) and Viet Nam (36%). The highest numbers of new cases were reported from Japan (156 931 new cases; 124.1 new cases per 100 000; a 5% increase), Malaysia (150 224 new cases; 464.1 new cases per 100 000; similar to the previous week), and the Philippines (111 904 new cases; 102.1 new cases per 100 000; a 16% increase).

The highest numbers of new deaths were reported from Viet Nam (2865 new deaths; 2.9 new deaths per 100 000; a 36% increase), Malaysia (1866 new deaths; 5.8 new deaths per 100 000; a 9% increase), and the Philippines (1412 new deaths; 1.3 new deaths per 100 000; a 7% decrease).

Updates from the [Western Pacific Region](#)

Summary of the COVID-19 Weekly Operational Update

The [Weekly Operational Update](#) (WOU) is a report provided by the COVID-19 Strategic preparedness and response plan (SPRP) monitoring and evaluation team which aims to update on the ongoing global progress against the [COVID-19 SPRP 2021](#) framework.

In this week's edition of the COVID-19 Weekly Operational Update, published on 30 August, highlights of country-level actions and WHO support to countries include:

- GeneXpert machine donated to Belize's Central Medical Laboratory
- Supporting quality management implementation, coordination and costing as part of the COVID-19 laboratory response in Kyrgyzstan
- 15 000 kg of medical supplies arrive in Fiji to support the response to a surge in COVID-19 cases
- Extending COVID-19 vaccination to Rohingya refugees in Cox's Bazar camps in Bangladesh
- Responding to COVID-19 in Jordan: The Innovative Use of Online Platforms
- The Elsje Finck-Sanichar College COVAB in Suriname embraces OpenWHO and online learning during COVID-19 pandemic
- Progress on a subset of indicators from the SPRP 2021 Monitoring and Evaluation Framework
- Updates on WHO's financing to support countries in SPRP 2021 implementation and provision of critical supplies.

For more information, see the [Weekly operational update on COVID-19](#)

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

WHO from official sources.

ation become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

COVID-19 Weekly Epidemiological Update

Edition 54, published 24 August 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 22 August 2021

With over 4.5 million new cases reported this week (16-22 August), the number of new cases reported globally seems to be stable after increasing for nearly two months (since mid-June) (Figure 1). The Regions of Western Pacific and Americas continue to report increases in new cases, with increases of 20% and 8% respectively as compared to last week. The South-East Asia and Eastern Mediterranean regions reported decreases in weekly incidence of 16% and 10% respectively. The European and African Regions reported case incidence rates similar to those reported last week.

The number of deaths reported globally this week remains similar to last week, with over 68 000 new deaths reported. Two Regions including Europe and Americas reported increases in new deaths of 11% and 10% respectively. The African and South-East Asia Regions reported decreases in new deaths of 11% and 10% respectively, whereas the numbers of deaths reported in the Eastern Mediterranean and Western Pacific Regions were similar to the numbers reported last week. The cumulative number of cases reported globally is now over 211 million and the cumulative number of deaths is just over 4.4 million.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 22 August 2021**

**See [Annex 2: Data, table and figure notes](#)

The Regions reporting the highest weekly case and deaths incidence rates per 100 000 population remain the same as last week: the Regions of the Americas (158.8 new cases per 100 000 population; 2.1 deaths per 100 000 population) and Europe (124.9 new cases per 100 000 population; 1.3 deaths per 100 000 population) . The Eastern Mediterranean Region also reported a high weekly incidence in deaths (1.0 per 100 000 population).

The highest numbers of new cases were reported from the United States of America (1 020 072 new cases; 15% increase), the Islamic Republic of Iran (251 610 new cases; 7% decrease), India (231 658 new cases; 10% decrease), the United Kingdom (219 919 new cases; 11% increase), and Brazil (209 099 new cases; 1% decrease).

Globally, cases of the Alpha variant have been reported in 192 countries (three new countries since last week), territories or areas (hereafter countries), while 141 countries (four new countries) have reported cases of the Beta variant; 86 countries (no new country) have reported cases of the Gamma variant; and 163 countries (seven new countries) have reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 22 August 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 623 891 (36%)	8%	81 746 260 (39%)	21 983 (32%)	10%	2 072 143 (47%)
Europe	1 165 092 (26%)	0%	63 662 465 (30%)	11 912 (17%)	11%	1 254 406 (28%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

Updates on VOCs and VOIs, and a list of Alerts for Further Monitoring, are available on the [WHO Tracking SARS-CoV-2 Variants website](#).

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of these COVID-19 Weekly Epidemiological Updates. Since the last detailed [update](#) on 10 August, new evidence has been published on the phenotypic characteristics of VOCs.

A preliminary population-level observational study conducted in Israel found that infection with the Alpha variant did not lead to higher case fatality rates. This finding contradicts previous studies from the United Kingdom that indicated an increase in the risk of severe outcomes and mortality associated with the Alpha variant¹. These findings could nonetheless be influenced by several factors such as much younger general population, high vaccination coverage and extensive free testing throughout Israel². Another prospective longitudinal household study (preprint) found a higher secondary attack rate among cases infected with the Alpha variant (77.8%) as compared to those infected with non-VOCs (42.5%) in Norway, suggesting the potential for very high household transmission levels for the Alpha variant. The same study also found that primary cases experiencing loss of taste/smell were associated with a significant increase in the onwards secondary attack rates, which could also be due to the observed increase in viral load^{3,4} in these cases.⁵

A systematic review (preliminary study) which aimed to understand the impact of the Alpha and Gamma variants on the rates of hospitalization of nine of these studies in the analysis. The study found that the relative risk of hospitalization is higher (between 1.4 to 2) for the Alpha variant as compared to non-VOCs. The evidence for hospitalization with the Gamma variant, compared to non-VOC was limited (only one

study was included), but the odds ratio of hospitalization was found to be much higher (above 2), particularly for cases between the age of 20-39 years.⁶

Results from a recent preprint study in the United States of America suggest that the Delta variant has greater replication fitness as compared to the Alpha variant, meaning that Delta has the propensity to replicate more easily and is in turn more infectious.⁷ The study identified a key spike protein mutation (P681R at the furin cleavage site) as the molecular determinant for the enhanced fitness of the Delta variant and its dominance over the Alpha variant. In a systematic review (preprint) comparing the basic reproductive number (R_0) of the Delta variant to the early R_0 estimates of non-VOC strains, the mean R_0 of the Delta variant was found to be 5.08, far higher than the R_0 of non-VOC strains (2.79).⁸ The authors of the study screened nearly 30 000 records, of which only 5 were identified as providing evidence that the true value of the R_0 of the Delta variant is likely under-estimated as the R_0 estimates in the studies identified were taken at the time when variable movement restrictions were in place in most parts of the world.

The emergence of these Variants of Concern highlight the importance of maintaining public health and social measures (PHSM) and the need to increase vaccination coverage against SARS-CoV-2. The timing of lifting these measures is critical as highlighted by a modelling study conducted in England whereby lifting the PHSM fully on 21 June, as originally planned, as opposed to 19 July, would have led to a peak of 3,400 (95% CI: 1,300-4,400) daily admissions to hospital due to the emergence of the Delta variant. Delaying the lifting of PHSL until 19 July reduced the peak in daily hospitalizations by nearly three fold to 1,400 (95% CI: 700-1500).⁹ It is important to note that these hospitalization rates were based on estimates, including uncertainties as to the effectiveness of vaccines against the Delta variant, which require careful interpretation. Relaxation of PHSM should therefore be carefully and cautiously balanced against levels of vaccination coverage, and the circulation of Variants of Concern.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility and secondary attack rate ¹⁰	Increased transmissibility ¹¹	Increased transmissibility ¹²	Increased transmissibility and secondary attack rate ¹³ Similar transmissibility between vaccinated and unvaccinated individuals ^{14–16}
Disease severity	Increased risk of hospitalization ¹⁷ , possible increased risk of severity and mortality ¹	Not confirmed, possible increased risk of in-hospital mortality ¹⁸	Not confirmed, possible increased risk of hospitalization ¹⁹	Increased risk of hospitalization ²⁰

Risk of reinfection	Neutralizing activity retained ²¹ , risk of reinfection remains similar ²²	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²³	Moderate reduction in neutralizing activity reported ²⁴	Reduction in neutralizing activity reported ^{25–27}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF); no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed ²⁸	No impact on RT-PCR or Ag RDTs observed ²⁷	None reported to date	None reported to date

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

VE refers to vaccine effectiveness and vaccine efficacy

Summary of VE*: indicates the general conclusions but only for the vaccines evaluated against the specific variant

Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used.

“Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the VIEW-hub Resources page (<https://view-hub.org/resources>).

For individual vaccine effectiveness studies, see ‘COVID-19 Vaccine Effectiveness Results Summary’, reference numbers noted with a ‘#’. For a list of all neutralization studies, see ‘COVID-19 Vaccine Neutralization Studies Table’.

References indicated by superscripts next to VOC name in column 1 are vaccine efficacy results from randomized controlled trials informing this table and are included in the reference section below.

Additional notes on VOC impacts on vaccines

- Studies presenting VOC-specific vaccine efficacy or effectiveness (VE) estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that vaccine product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for severe disease (phase 3 RCT efficacy estimates against severe disease are used as comparator since a within study comparator is unavailable) and for infection (when phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.

Table 3 presents the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of variants compared to VE in non-VOC settings. Of note, reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of $\sim 85\%$. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection, as is the case for AstraZeneca-Vaxzevria.

Since the [10 August update](#), four notable studies have assessed vaccine effectiveness against SARS-CoV-2 Variants of Concern. A test-negative case-control study from Qatar (preprint) evaluated the effectiveness of mRNA vaccines against symptomatic and severe COVID-19 disease due to Delta. VE against symptomatic Delta infection ≥ 14 days post second dose was 56.1% (95% CI: 41.4-67.2%) for Pfizer BioNTech-Comirnaty and 85.8% (95% CI: 70.6-93.9%) for Moderna-mRNA-1273. The lower VE for Pfizer BioNTech-Comirnaty may be explained by a lower VE against Delta and/or by waning of protection with time. The VE against symptomatic disease due to Delta for Pfizer BioNTech-Comirnaty is lower than that found by studies conducted in the UK and Canada^{36–38} where, due to the longer interval between doses, most of the study population had received their second dose 3 months later than in the study in Qatar. The same drop in VE was not observed in this study for the Moderna-mRNA-1273 vaccine, which may be due to the vaccine being introduced into Qatar three months later than Pfizer BioNTech-Comirnaty and being administered with a slightly longer dosing interval (i.e., 4 weeks instead of 3 weeks). Third, as the authors note, differential application of restrictions in Qatar could have contributed to a lower VE, with some restrictions in Qatar eased for the vaccinated while maintained for the unvaccinated. Importantly, VE against hospitalization and death due to Delta remained high (VEs of 97-100%) for both vaccines. Finally, persons with a prior history of SARS-CoV-2 infection were not excluded from this study which could downwardly bias VE estimates if a substantial proportion of the unvaccinated population has natural immunity.³⁹

Two studies from the United States of America evaluated VE of Pfizer BioNTech-Comirnaty and Moderna-mRNA-1273 vaccines during a period of high Delta prevalence (June-July 2021). The first, a retrospective cohort study found decreased VE against infection among nursing home residents during June-July 2021 when Delta predominated as compared to the period of March-May 2021. VE against infection from June-July 2021 was 52.4% (95% CI: 48.0-56.4%) and 50.6% (95% CI: 45.0-55.7%) for Pfizer BioNTech-Comirnaty and

Moderna-mRNA-1273 vaccines, respectively. Corresponding VE during March-May were 74.2% (95% CI: 69.0-78.7%) and 74.7% (95% CI: 66.2-81.1%). It is not possible to know whether decreased VE during the later time period was due to the Delta variant or due to waning of protection. The estimates are also limited due to the inability to control for potential confounders.⁴⁰ The second study, a case-control study of adults ≥ 18 years, found VE of Pfizer BioNTech-Comirnaty or Moderna-mRNA-1273 vaccines found that protection against hospitalization ≥ 14 days post second dose was maintained during the period when Delta was predominant (VE of 84%, 95% CI: 79-89%) as compared to the pre-Delta period (VE of 87%, 95% CI: 83-90%).

41

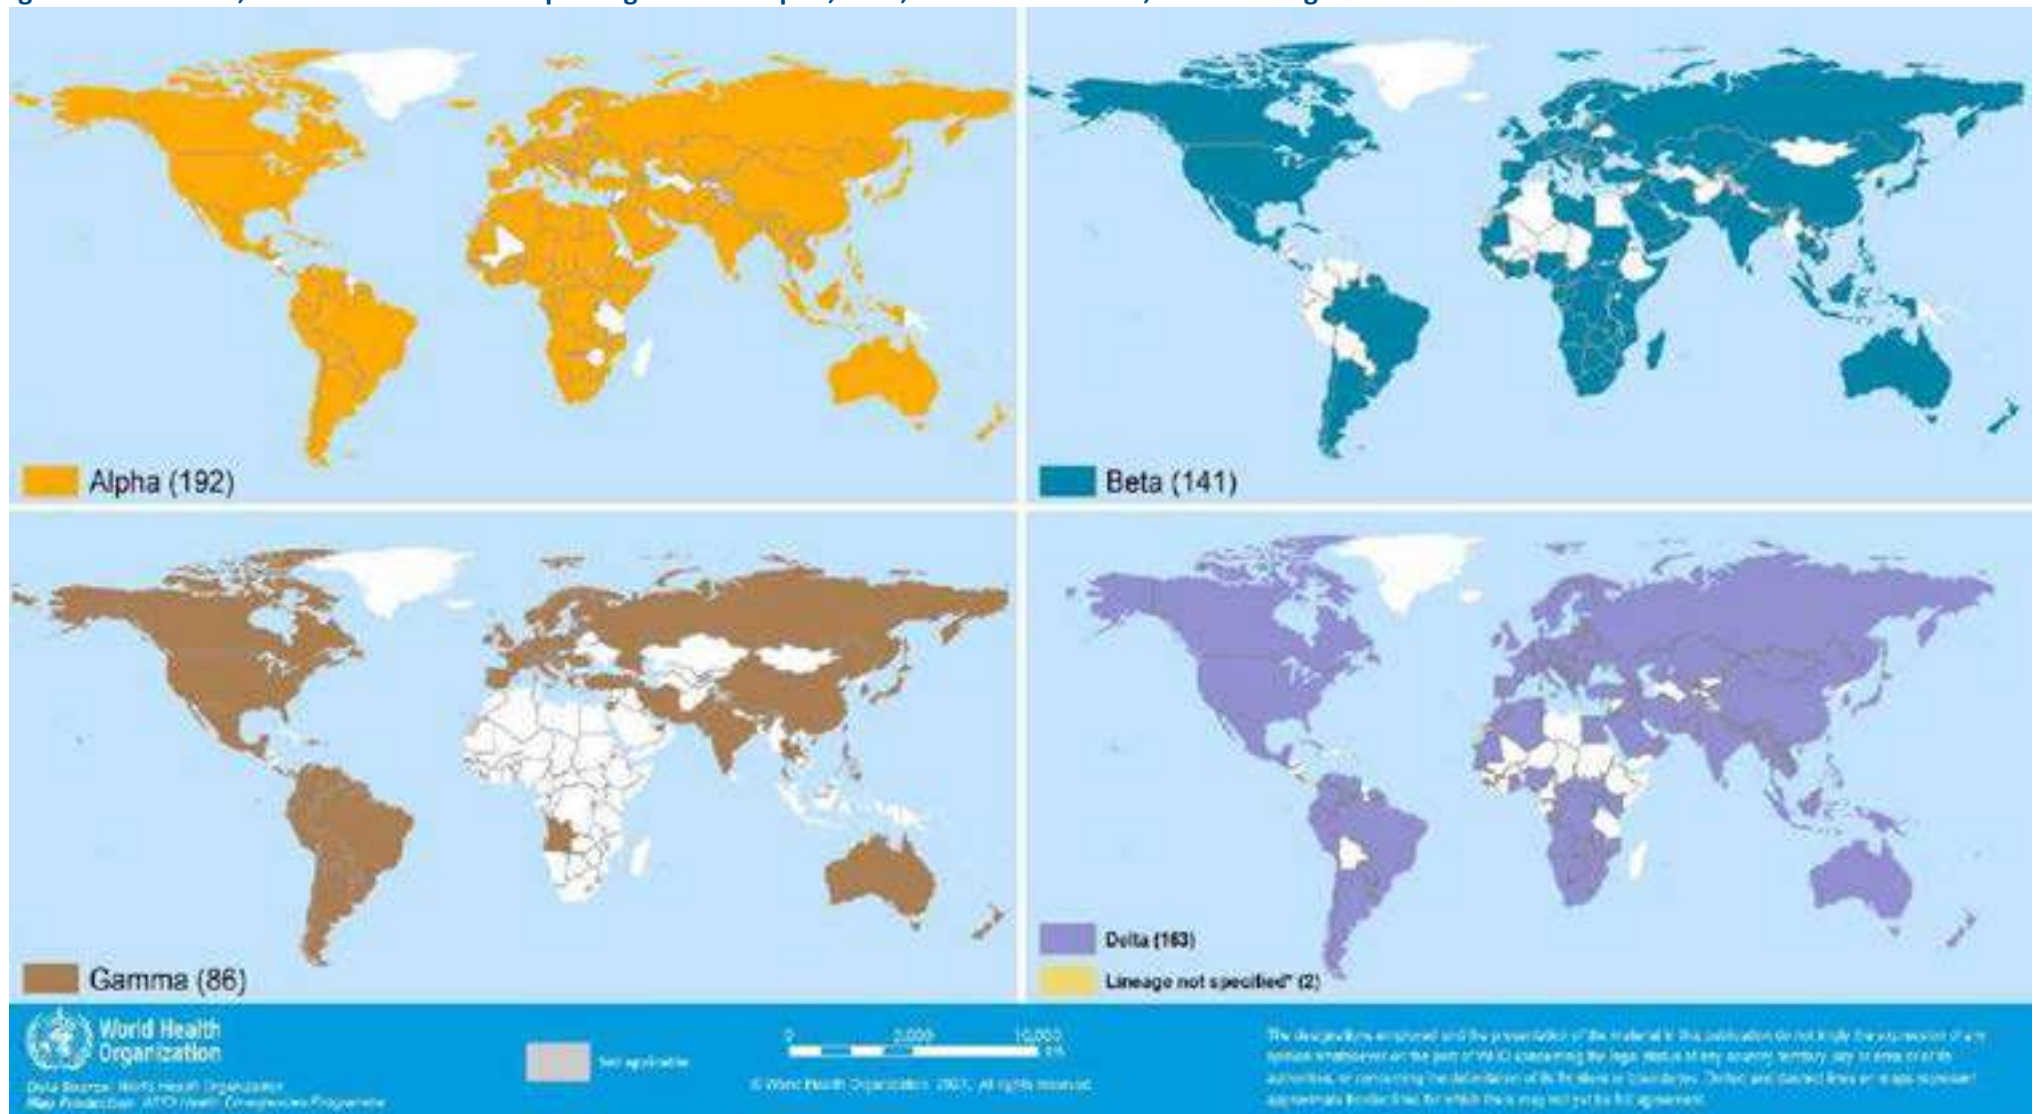

The fourth study, from the UK (preprint), assessed VE of Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines against SARS-CoV-2 infection (asymptomatic and symptomatic) among adults ≥ 18 years through a large survey of randomly selected households. The study compares VE during a period of high Alpha prevalence to that of a period of high Delta prevalence. Findings showed possible reduced effectiveness of AstraZeneca-Vaxzevria vaccine in the period when Delta was most dominant compared to when Alpha was dominant: 67% (95% CI: 62-71%) vs 79% (95% CI: 56-90%). No reduction was observed for Pfizer BioNTech-Comirnaty: VE was 78% (95% CI: 68-84%) during the period when Alpha was dominant and 80% (95% CI: 77-83%) during when Delta was most dominant. One-dose effectiveness for both vaccines was markedly lower: VE of nearly 60% during both periods for Pfizer BioNTech-Comirnaty and VE estimates of 63% and 46% for AstraZeneca-Vaxzevria during the time the Alpha and Delta variants were predominant, respectively. The study also estimates one-dose VE of Moderna-mRNA-1273 against SARS-CoV-2 during the period the Delta variant was predominant to be 75% (95% CI: 64% - 83%), higher than that of the other vaccines although this could be in part due to predominantly younger persons receiving Moderna-mRNA-1273.⁴²

Together these studies provide evidence for the maintenance of high levels of protection against severe COVID-19 disease due to Delta. While there is some evidence that VE against SARS-CoV-2 infection and non-severe disease may be reduced with Delta, it is currently not possible to separate the effect of Delta from the effect of potential waning immunity, differential risk of exposure profiles between vaccinated and unvaccinated populations, spuriously low VE due to increasing levels of natural immunity in the unvaccinated population, or other potential confounding factors.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 24 August 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews – Epidemiological week 16 – 22 Aug 2021

African Region

The Region reported a similar weekly case incidence as compared to last week, with over 158 500 new cases reported this week. Overall, since the 5 July, the Region continues to show a declining trend in weekly new cases. This week, around half (53%) of the weekly new cases were reported from South Africa. Weekly new deaths have been declining for past four consecutive weeks, and a sharp decrease (by 11%) was reported this week as compared to last week, with just over 3900 new deaths reported. A total of 17 of 49 countries/territories/areas reported an increase in weekly case incidence, with highest increase reported in Benin and Sao Tome and Principe.

This week, the highest numbers of new cases were reported from South Africa (84 778 new cases; 142.9 new cases per 100 000 population; an 18% increase), Botswana (9703 new cases; 412.6 new cases per 100 000; a 32% decrease), and Kenya (8425 new cases; 15.7 new cases per 100 000; a 5% decrease). The highest numbers of new deaths were reported from South Africa (2382 new deaths; 4.0 new deaths per 100 000 population; a 6% increase), Algeria (218 new deaths; <1 new deaths per 100 000; a 22% decrease), and Kenya (148 new deaths; <1 new deaths per 100 000; a 27% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.6 million new cases and just under 22 000 new deaths, an 8% and a 10% increase respectively compared to the previous week. This increase is mainly driven by increase in cases in the United States of America which accounted for 63% of all new cases reported this week. Overall, cases continue to increase for past three weeks in the Region. In South America, most countries reported a decline in new cases, with the exception of El Salvador and Costa Rica which reported increases in new cases of 45% and 6% respectively as compared to last week.

The highest numbers of new cases were reported from the United States of America (1 020 072 new cases; 308.2 new cases per 100 000; a 15% increase), Brazil (209 099 new cases; 98.4 new cases per 100 000; a 1% decrease), and Mexico (128 779 new cases; 99.9 new cases per 100 000; a 4% increase). Similarly, the highest numbers of new deaths were reported from the United States of America (6712 new deaths; 2.0 new deaths per 100 000; a 58% increase), Brazil (5649 new deaths; 2.7 new deaths per 100 000; a 7% decrease), and Mexico (4666 new deaths; 3.6 new deaths per 100 000; a 27% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The majority of countries in the Eastern Mediterranean Region (13/22; 59%) reported declining trends this week and for the first time since the end of May, the Region reported a 10% decrease in cases, with just over 450 000 new cases this week. These declines were largely due to decreases in the number of new cases reported in the Islamic Republic of Iran, Morocco, Pakistan and Iraq, although it is important to note that there is still ongoing transmission in all countries in the Region and case numbers while declining, remain high in most countries. Following seven weeks of increasing death incidence, this week over 7100 new deaths were reported in the Region, a number similar to that of the previous week. Eight out of the twenty-two countries reported increases in deaths over the past seven days.

The highest numbers of new cases were reported from the Islamic Republic of Iran (251 610 new cases; 299.6 new cases per 100 000; a 7% decrease), Morocco (54 212 new cases; 146.9 new cases per 100 000; a 16% decrease), and Iraq (50 702 new cases; 126.1 new cases per 100 000; a 21% decrease). The highest numbers of new deaths were reported from the Islamic Republic of Iran (4146 new deaths; 4.9 new deaths per 100 000; an 11% increase), Morocco (744 new deaths; 2.0 new deaths per 100 000; a 10% increase), and Tunisia (630 new deaths; 5.3 new deaths per 100 000; a 30% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The number of new cases in the European Region remained similar to that of the previous week with over 1.1 million new cases reported. With just under 12 000 deaths reported this week, the weekly deaths in the Region represent the largest proportionate increase (11%) seen across all six WHO regions this week as compared to the previous week. In the past week, this increase in new deaths was largely due to increases in deaths reported in France (74%), Italy (54%) and Turkey (44%).

The highest numbers of new cases were reported from The United Kingdom (219 919 new cases; 324.0 new cases per 100 000; an 11% increase), Russian Federation (146 251 new cases; 100.2 new cases per 100 000; a 4% decrease), and Turkey (137 235 new cases; 162.7 new cases per 100 000; a 16% decrease). The highest numbers of new deaths were reported from Russian Federation (5545 new deaths; 3.8 new deaths per 100 000; a 1% decrease), Turkey (1322 new deaths; 1.6 new deaths per 100 000; a 44% increase), and Kazakhstan (930 new deaths; 5.0 new deaths per 100 000; a 0% decrease).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 614 000 new cases this week, a 16% decrease as compared to the previous week and the largest proportional decrease across all six WHO regions. All countries in the Region reported a decrease in the number of weekly cases, except from Maldives, Sri Lanka, and Timor-Leste where the number of new cases increased by 6%, 40%, and 59% respectively. This week the Region reported 17 000 new deaths, a 10% decrease respectively compared to the previous week, although half of the countries (5/10; 50%) continued to report increases.

The highest numbers of new cases were reported from India (231 658 new cases; 16.8 new cases per 100 000; a 10% decrease), Thailand (142 138 new cases; 203.6 new cases per 100 000; a 6% decrease), and Indonesia (125 102 new cases; 45.7 new cases per 100 000; a 34% decrease). The highest numbers of new deaths were reported from Indonesia (8784 new deaths; 3.2 new deaths per 100 000; a 16% decrease), India (3142 new deaths; 0.2 new deaths per 100 000; a 7% decrease), and Thailand (1768 new deaths; 2.5 new deaths per 100 000; a 31% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The number of new cases in the Western Pacific Region continued to increase this week with over 513 000 new cases, a 20% increase as compared to the previous week. Regionally, 14 of the 18 countries (78%) reported increasing trends this week, although sharp increases in case incidence in Malaysia, Viet Nam, Japan and Philippines are responsible for much of the regional increase. In the past week, although the number of deaths remained similar to that of the previous week with just under 5900 new deaths reported, a quarter of the countries (6/24) in the region reported significant proportionate increases (<30%) in the number of new deaths reported.

The highest numbers of new cases were reported from Malaysia (150 933 new cases; 466.3 new cases per 100 000; a 7% increase), Japan (149 057 new cases; 117.9 new cases per 100 000; a 34% increase), and the Philippines (96 724 new cases; 88.3 new cases per 100 000; a 25% increase). The highest numbers of new deaths were reported from Viet Nam (2103 new deaths; 2.2 new deaths per 100 000; a 4% decrease), Malaysia (1708 new deaths; 5.3 new deaths per 100 000; a 7% decrease), and the Philippines (1526 new deaths; 1.4 new deaths per 100 000; a 24% increase).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his opening remarks at the 18 August [media briefing on COVID-19](#), the Director-General called for
 - a moratorium on booster shots to help shift supply to those countries that have not been able to vaccinate their health workers or at risk-risk communities and are now experiencing major surge in cases.
 - equitable allocation of Interleukin-6 blockers, a drug that has shown a reduction in death amongst patients hospitalised with severe COVID-19.
- In his opening remarks at on 19 August, the Director-General provided an update on the setting up of a permanent International [Scientific Advisory Group on the Origins of Novel Pathogens \(SAGO\)](#) to establish a more systematic way of identifying the source of new outbreaks. SAGO will play a vital role in studying the emergence of new pathogens, including the origins of SARS-CoV-2.

Updates and publications

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

○ from official sources.

ation become available.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 53, published 17 August 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [Special focus: COVID-19 in Prisons](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 15 August 2021

The global number of new cases has been increasing for the last two months, with over 4.4 million cases reported in the past week (9 – 15 August 2021) (Figure 1). This increasing trend is largely attributed to increases in the Western Pacific Region and the Region of the Americas which reported 14% and 8% increases respectively as compared to the previous week; the other four regions reported similar or a decrease in new weekly cases as compared to the previous week. The cumulative number of cases reported globally is now over 206 million and the cumulative number of deaths is almost 4.4 million. All regions except the Western Pacific and the Eastern Mediterranean Regions reported similar or a decrease in the number of deaths this week as compared to the previous week. While the African Region reported the largest decline in cases and deaths, with 23% and 18% decreases in incidence respectively, data from the weekend is incomplete which may overestimate differences as compared to the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 15 August 2021**

**See [Annex 2: Data, table and figure notes](#)

The regions with the highest weekly incidence rates of cases and deaths per 100 000 population remain the same as last week: the Region of the Americas and the European Region reported the highest weekly case (147.4 and 121.6 new cases per 100 000 population, respectively) and death incidence (2.0 and 1.1 new deaths per 100 000 population, respectively).

At the country level, the highest numbers of new cases in the past week were reported by the United States of America (883 996 new cases; 9% increase), the Islamic Republic of Iran (26 9975 new cases, 9% increase), and India (258 121 new cases; 7% decrease). However, the highest numbers of new deaths in the past week were reported by Indonesia (10 492996 new cases; 8% decrease), Brazil (6100 new cases, 3% decrease) and the Russian Federation (5618 new cases; a 2% increase).

Globally, cases of the Alpha variant have been reported in 190 countries, territories or areas (hereafter countries), while 138 countries (one new country) have reported cases of the Beta variant; 82 countries (one new country) have reported cases of the Gamma variant; and 148 countries (three new countries) have reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 15 August 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 507 234 (34%)	8%	80 121 215 (39%)	19 956 (30%)	1%	2 050 072 (47%)
Europe	1 134 516 (26%)	1%	62 474 616 (30%)	10 495 (16%)	-3%	1 242 204 (29%)
South-East Asia	731 279 (16%)	-9%	39 908 781 (19%)	19 401 (29%)	-6%	610 389 (14%)
Eastern Mediterranean	502 683 (11%)	0%	13 601 389 (7%)	7 034 (11%)	15%	249 389 (6%)
Western Pacific	429 153 (10%)	14%	5 330 671 (3%)	5 711 (9%)	23%	75 433 (2%)
Africa	139 767 (3%)	-23%	5 276 855 (3%)	3 909 (6%)	-18%	125 934 (3%)
Global	4 444 632 (100%)	2%	206 714 291 (100%)	66 506 (100%)	0%	4 353 434 (100%)

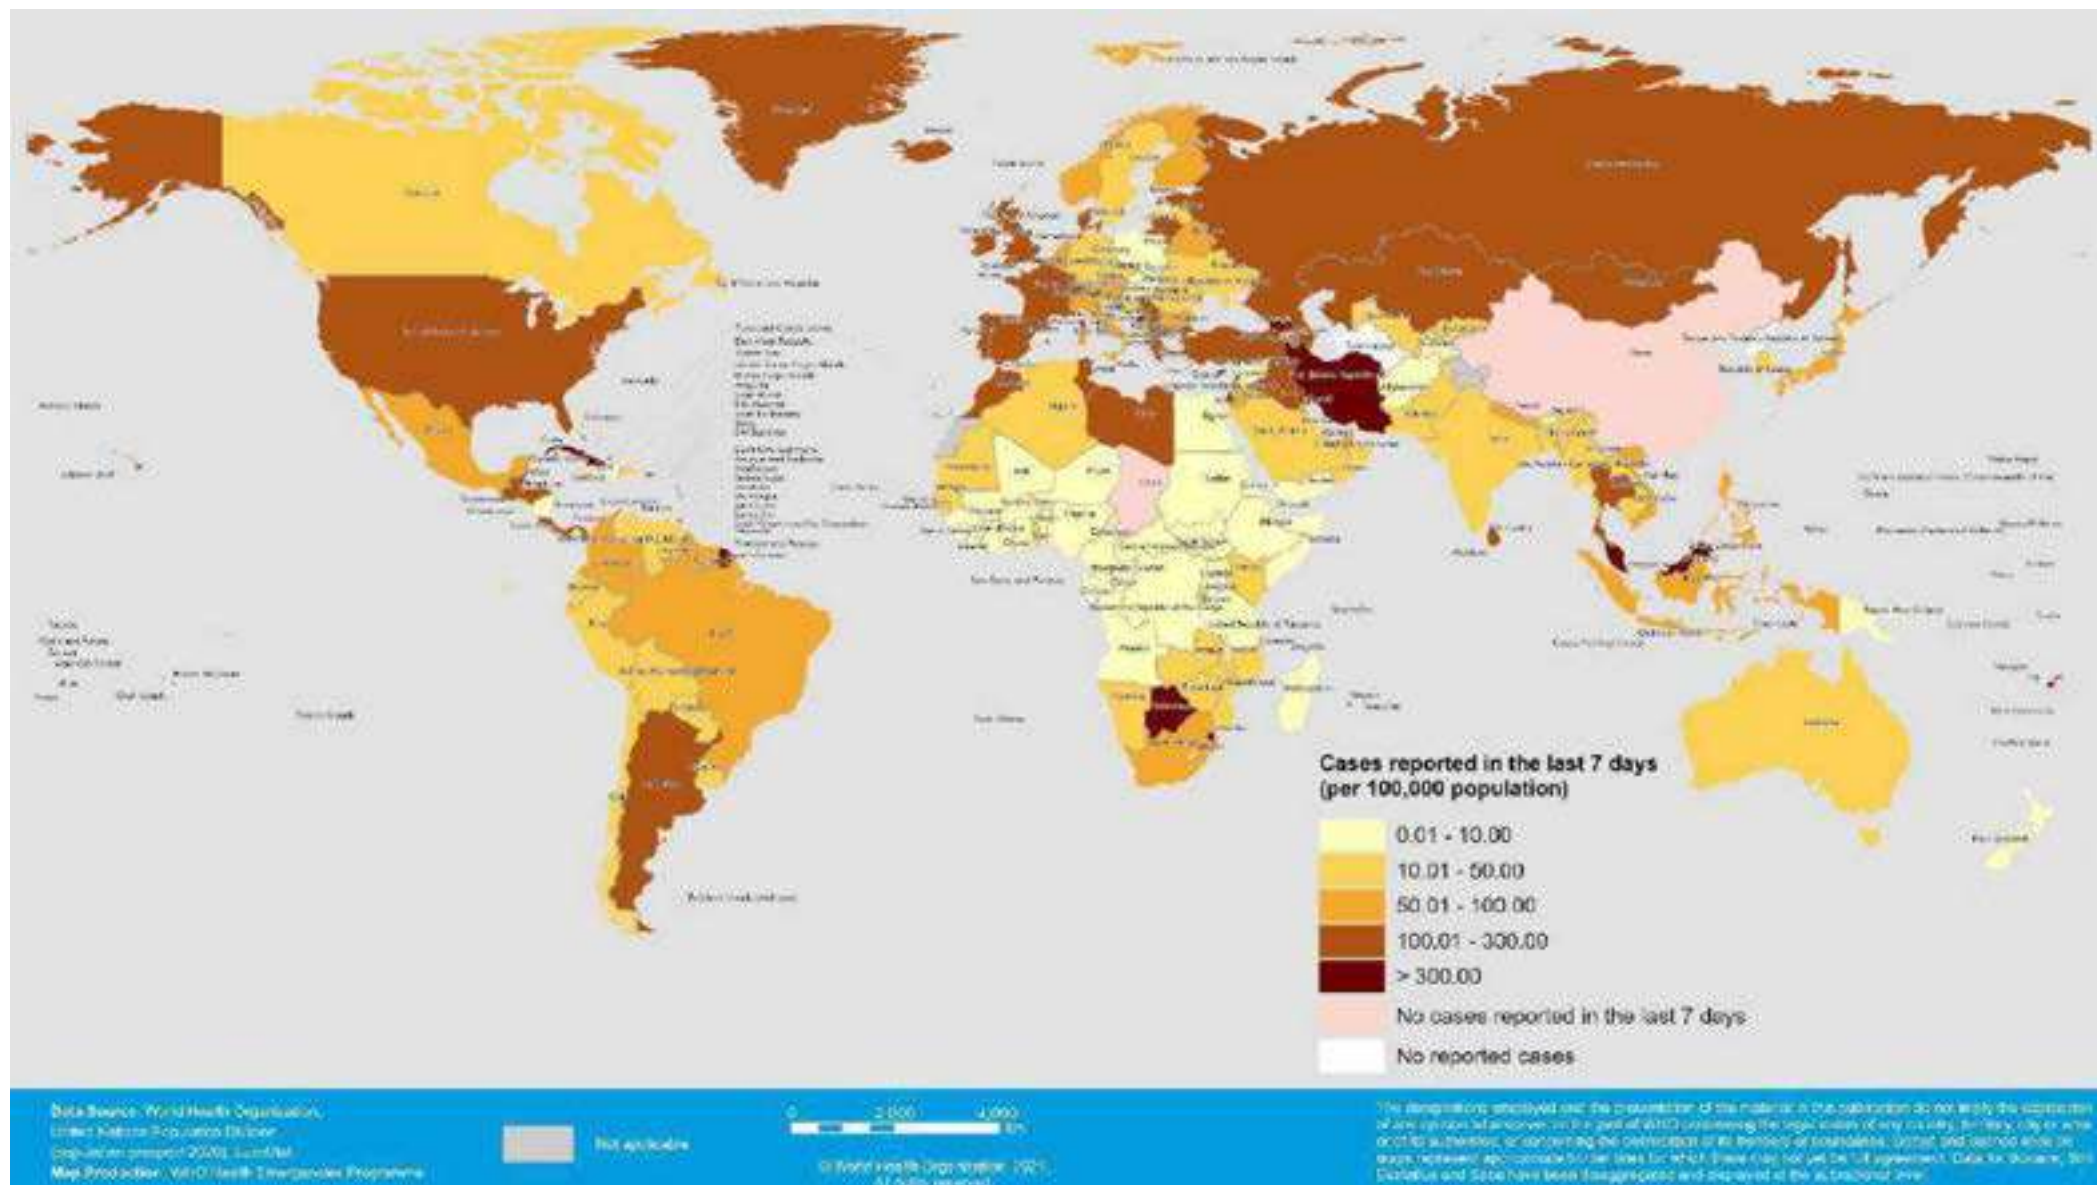

*Percent change in the number of newly confirmed cases/deaths in the past seven days, compared to the seven days prior

**See [Annex 2: Data, table and figure notes](#)
