WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As these risks evolve, WHO will continue to update the lists of global VOIs and VOCs to support prioritization for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website).

National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on the impacts of these variants.

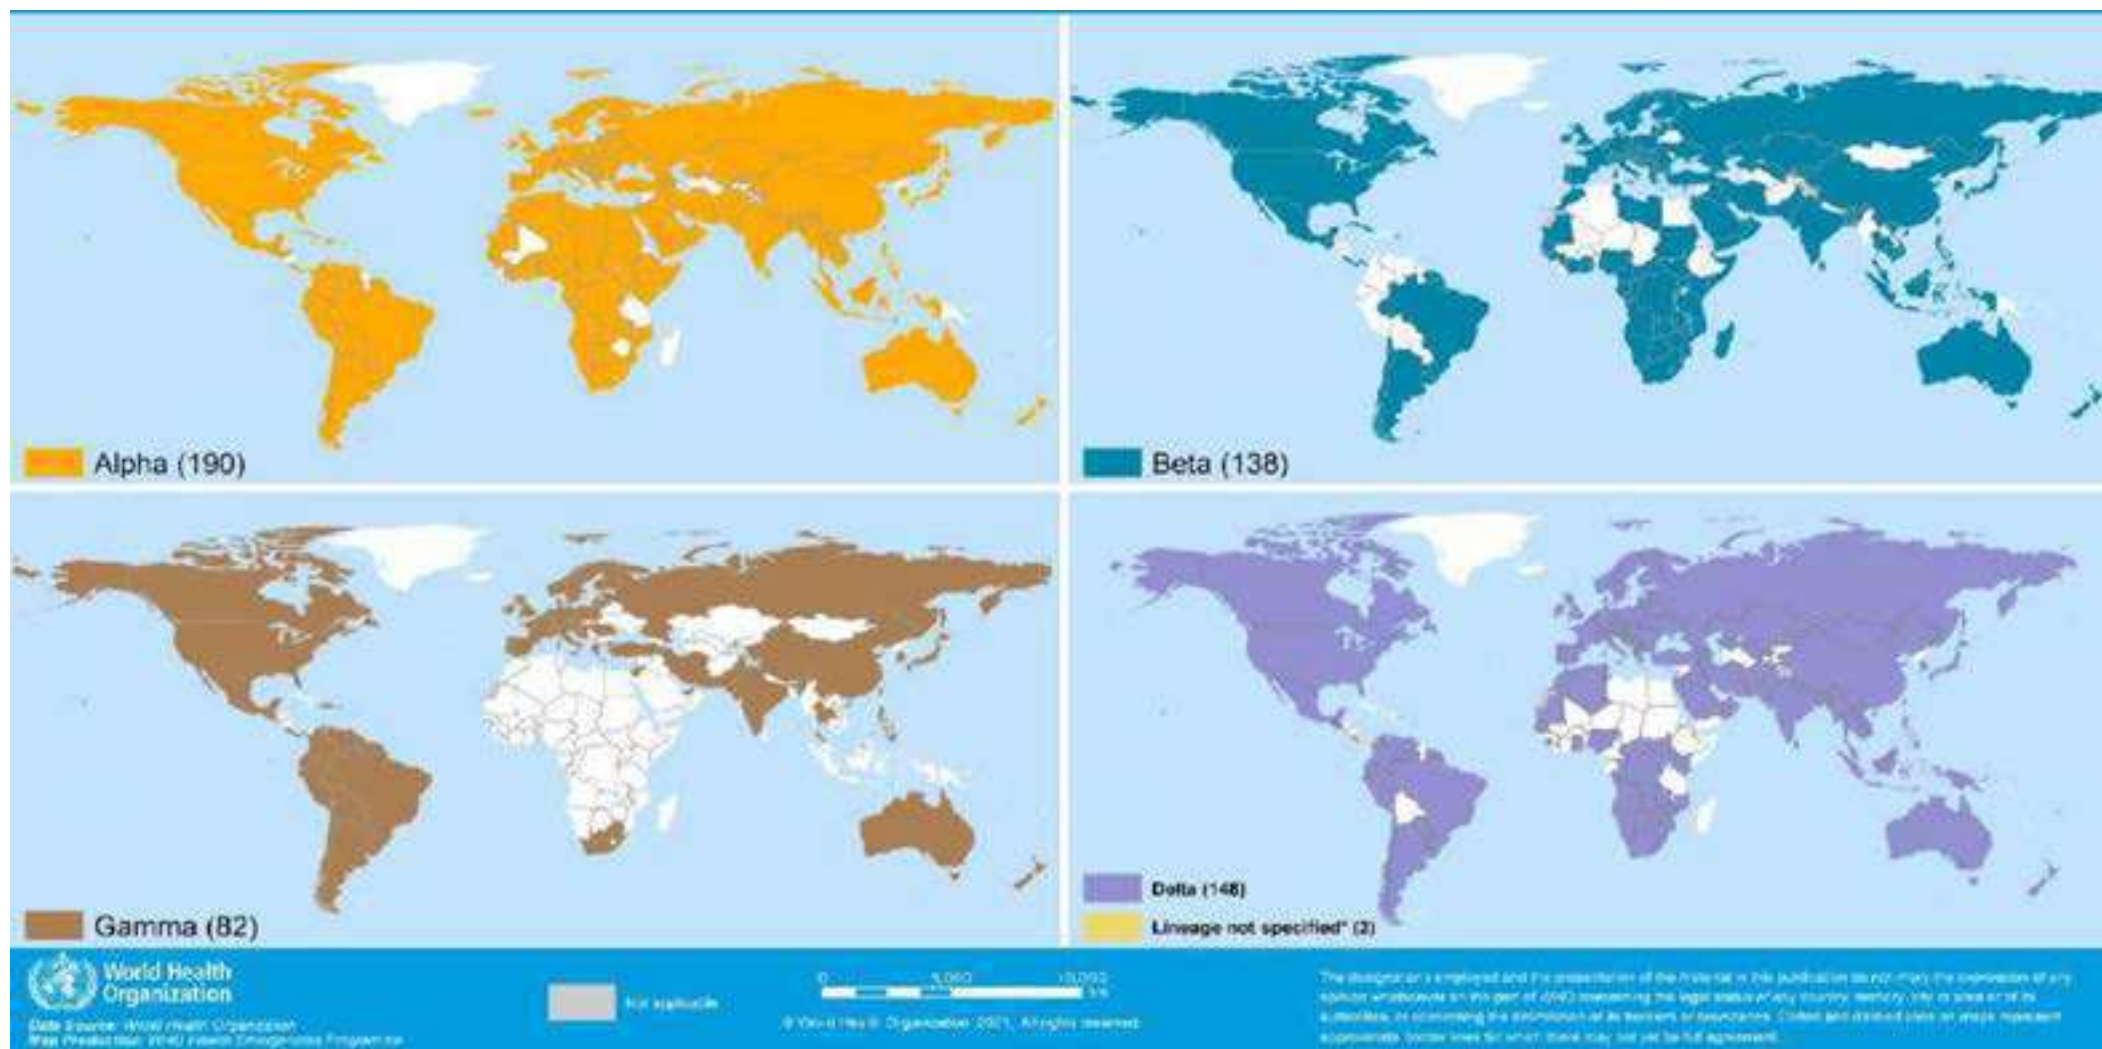

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on a thorough risk assessment conducted systematically and routinely.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 17 August 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see Annex 2 for further details.

Special Focus: COVID-19 in Prisons

Prisons are unique environments for pathogen transmission due to high population density, overcrowding, and proximity among detainees and guards. Since the beginning of the pandemic, outbreaks of COVID-19 have been reported in prisons and correctional facilities in at least 122 countries across the world.¹ COVID-19 outbreaks in detention centers have been reported in countries across all WHO regions.² Early in the pandemic, and in response to a request made by Member States, the WHO Health In Prisons Programme (WHO/HIPP; based out of the WHO Regional Office for Europe) published interim guidance on 15 March 2020 to support countries in preparedness, prevention and control of COVID-19 in prisons and other places of detention. As the pandemic progressed, further understanding of the pathophysiology of COVID-19 informed a revision, which was published on 8 February 2021. The revised guidance included updates on the signs and symptoms, transmission of the virus that causes COVID-19 and the measures to prevent infection. It also addressed issues of vaccine availability and allocation and advised on indicators for the surveillance of COVID-19 in detention settings.

To enable monitoring of the evolution of the pandemic in detention settings, WHO developed a minimum set of indicators, which Member States have been voluntarily reporting to WHO/HIPP since April 2020. The indicators requested include information on the operational capacity and on the number of individuals living in prisons (disaggregated by age categories and sex) to monitor the occupancy rate over time; the number of individuals tested and diagnosed with SARS-CoV-2 infection (also disaggregated by age category, sex and divided by staff and detainees); those being transferred to hospital and those who have died. This minimum dataset was revised in February 2021 to include vaccination in detainees, staff and health care workers. As this is a voluntary system, reporting by Member States is not consistent and only 18 Member States have submitted data to WHO/HIPP since the system was established. The submitted data are analyzed on a weekly basis to compare the epidemiology of COVID-19 in detention facilities with that observed in the general population. This comparison enables the early identification of outbreaks that could benefit from WHO's technical support.

Despite a clear positive progression in the reporting capacity of Member States, in some countries it is challenging to separate the subsection of COVID-19 data attributable to detainees or detention center staff within larger public health datasets. Disaggregating the data in prison health information systems from the general public health data would allow for a more specific and tailored evaluation of the evolving situation and burden of the COVID-19 pandemic within these settings.

Summarizing the evidence: Early analysis conducted on persons living in prisons (from January to June 2020) identified 42 107 cases of SARS-CoV-2 infection and 510 deaths among nearly 1.3 million people living in prisons, in the United States of America. This is similar to the case rate of 3251 per 100 000 population reported in the same country and 5.5 times higher than that in people of the same age and sex in the general population across the same time period.³ Among prison staff, the case rate reported up to November 2020 was 3.2 times higher than in community settings in the United States of America.⁴ Based on data between 31 March and 6 June 2020, the estimated mortality rate among people in prisons was 39 per 100 000 compared to 29 per 100 000 for the general population of the United States of America.⁵ In the WHO European region, some countries have observed a mortality rate 3.3 times higher in detention centers compared to people of the same age and sex in the general population between March 2020 and February 2021.⁶

Overcrowding in prisons has negative consequences on health. For COVID-19, one study has shown that when prison capacity exceeds 85%, there is an increased risk of SARS-CoV-2 infection and death.⁷ In an effort to reduce overcrowding, the adoption of non-custodial measures, including decarceration of non-violent offenders, pardons and home confinement, are among some of the most commonly adopted measures globally. A survey conducted between March and June 2020 indicated that 109 countries took such measures, resulting in an average reduction of the prison population by 6%.⁸ These COVID-19 mitigation measures were in line with the call from the United Nations High Commission for Human Rights and the UN System common position on incarceration⁹ The mitigation measures implemented were considered crucial as overcrowding posed issues in being able to prevent and control COVID-19 outbreaks. Overcrowding also adversely affects access to health care and essential, basic hygiene practices products such water and soap. Despite these measures being implemented, overcrowding and its implications on SARS-CoV-2 transmission and other health issues continues to be a challenge in prisons.^{10, 11}

An effective measure used to control transmission of SARS-CoV-2 in detention centers has been the implementation of intensive epidemiological surveillance and contact tracing.¹² However, in many countries, due to limited resources, the capacity to routinely identify SARS-CoV-2 infections in detention centers is insufficient, making it difficult to ascertain the true burden of the disease in these settings.¹³

A potential strategy to ensure more representative COVID-19 case and mortality identification is to increase testing efforts. A study conducted in 16 facilities, in the United States of America, showed that mass testing increased the detection of cases by nearly 13-fold.¹⁴ Some countries in the European Region have intensified their testing strategy in the most recent months. While effective, this approach may not be feasible in every country and where this is the case, alternative approaches to testing in settings with limited resources have been recommended in WHO guidance.

As the availability of testing and COVID-19 vaccines has increased in a number of countries, advocacy for equitable access to vaccines among people living and working in detention centers continues.¹⁵ Many Member States have been working to increase the vaccine coverage among people living in detention centers with this coverage in the European Region, where this data is available, varying between less than 15% to above 60% coverage, and others not reporting on vaccination rollout in detention centers.

It is important to understand the impact of the pandemic in prisons, including the numbers of cases identified and the associated outcomes. Governments assume fully accountability for the health and well-being of detainees; therefore, providing detainees with protection from COVID-19 is a fundamental component of upholding their human rights. Furthermore, people living in prisons are not isolated from communities: there is constant movement of staff and visitors, and detainees are admitted, released and transferred frequently. Protecting those in detention will therefore have an impact on the surrounding communities and potentially on the capacity of the healthcare system.

Much progress has been made in the identification, detection and control of COVID-19 in some detention centers around the world. As the pandemic evolves, this progress must continue to better align health outcomes in prisons with overall public health goals.

WHO regional overviews - Epidemiological week 9 - 15 August 2021

African Region

This week, the data for the African Region is incomplete due to reporting delays and trends should be interpreted with caution until the missing data has been incorporated. The Region reported just over 139 000 new cases and over 3900 new deaths. The overall decrease in weekly cases reported in the region since the middle of July has been largely driven by declines observed in South Africa. In contrast, many other countries in the region continue to report increases in case incidence. For mortality, the trend in the region is largely driven by a decline in new weekly deaths reported by a majority of the countries in the Region, including Mozambique, South Africa, Zambia and Zimbabwe among others. This decrease in overall weekly mortality could be partly due to the lack of reporting of regional data for 15 August.

The highest numbers of new cases were reported from South Africa (58 939 new cases; 99.4 new cases per 100 000 population; 22% decrease), Botswana (14 184 new cases; 603.2 new cases per 100 000; 11% decrease), and Kenya (7685 new cases; 14.3 new cases per 100 000; 2% decrease). The highest numbers of new deaths were reported from South Africa (2008 new deaths; 3.4 new deaths per 100 000 population; 23% decrease), Botswana (269 new deaths; 11.4 new deaths per 100 000; 99% increase), and Zimbabwe (247 new deaths; 1.7 new deaths per 100 000; 16% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.5 million new cases and nearly 20 000 new deaths in the past week. While the number of cases increased by 8% as compared to last week, the number of weekly deaths was similar to the week before. Dominica, Saint Vincent and the Grenadines and Guadeloupe reported the largest percentage increase in weekly case incidence over the past seven days.

The highest numbers of new cases were reported from the United States of America (883 996 new cases; 267.1 new cases per 100 000; 20% increase), Brazil (210 254 new cases; 98.9 new cases per 100 000; 8% decrease), and Mexico (124 103 new cases; 96.3 new cases per 100 000; 8% increase). The highest numbers of new deaths were reported from Brazil (6100 new deaths, 2.9 new deaths per 100 000 population, 3% decrease), the United States of America (4245 new deaths; 1.3 new deaths per 100 000; 25% increase), and Mexico (3681 new deaths; 2.9 new death per 100 000; 12% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 502 000 new cases and over 7000 new deaths this past week. While the number of cases reported were similar to those reported in the previous week, the number of weekly deaths increased by 15%. This week, the region reported the highest weekly number of deaths since the beginning of the pandemic. The increase in deaths was mainly driven by an increase in new deaths reported by several countries in the region, including the Islamic Republic of Iran, Morocco, Pakistan, Syrian Arab Republic and Yemen.

The highest numbers of new cases were reported from the Islamic Republic of Iran (269 975 new cases; 321.4 new cases per 100 000; 9% increase), Morocco (64 784 new cases; 175.5 new cases per 100 000; 2% increase), and Iraq (64 390 new cases; 160.1 new cases per 100 000; 17% decrease). The highest numbers of new deaths were reported from the Islamic Republic of Iran (3735 new deaths; 4.4 new deaths per 100 000; 31% increase), Tunisia (896 new deaths; 7.6 new deaths per 100 000; 17% decrease), and Morocco (678 new deaths; 1.8 new deaths per 100 000; 44% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 1.1 million new cases and over 10 000 new deaths, similar numbers to those reported the previous week. While overall, the region is starting to plateau in terms of new weekly cases and deaths, most of the countries in the region continue to see significant increases in the number of weekly cases, including Azerbaijan, Georgia, Israel, Kosovo, Montenegro and North Macedonia. Following a gradual increase in weekly death incidence for the sixth week in a row, a slight decrease in the number of new deaths was reported over the last seven days.

The highest numbers of new cases were reported from the United Kingdom (198 759 new cases; 292.8 new cases per 100 000; 7% increase), Turkey (163 965 new cases; 194.4 new cases per 100 000; 3% decrease), and the Russian Federation (153 086 new cases; 104.9 new cases per 100 000; 4% decrease). The highest numbers of new deaths were reported from the Russian Federation (5618 new deaths; 3.8 new deaths per 100 000; 2% increase), Kazakhstan (934 new deaths; 5.0 new deaths per 100 000; 46% decrease), and Turkey (917 new deaths; 1.1 new deaths per 100 000; 21% increase).

Updates from the [European Region](#)

South-East Asia Region

Cases in the South-East Asia Region continued to decline this week. The region reported just over 731 000 new cases and 19 000 new deaths, decreases of 9% and 6% respectively, as compared to the previous week. Following a spike in the regional mortality rate two weeks ago, the number of new deaths has been declining following large decreases reported in the Maldives and Myanmar. While most of the countries reported decreases or similar numbers of cases this week, Sri Lanka, Thailand, and Timor-Leste reported increases in case incidence. Similarly, not all countries follow the regional declining trend in deaths as large increases were reported in a number of countries including Sri Lanka, Thailand and Timor-Leste this week, an increase of 63%, 11% and 200% respectively. The highest numbers of new cases were reported from India (258 121 new cases; 18.7 new cases per 100 000; 7% decrease), Indonesia (188 323 new cases; 68.9 new cases per 100 000; 17% decrease), and Thailand (150 652 new cases; 215.8 new cases per 100 000; 7% increase).

The highest numbers of new deaths were reported from Indonesia (10 492 new deaths; 3.8 new deaths per 100 000; 8% decrease), India (3363 new deaths; 0.2 new deaths per 100 000; 4% decrease), and Bangladesh (1523 new deaths; 0.9 new deaths per 100 000; 12% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported the largest proportionate increases in cases and deaths this week, with over 429 000 new cases and 5700 new deaths, increases of 14% and 23% respectively, as compared to the previous week. This exponential increase in cases and deaths has been ongoing for nearly two months. Over half of the countries and territories in the region that are providing regular data to WHO are reporting an increase in cases (10/18; 56%) and nearly half are reporting increases in deaths (8/18; 44%). The largest proportionate increases in cases and deaths were seen in Australia, French Polynesia, Japan, Philippines and Republic of Korea. The highest numbers of new cases were reported from Malaysia (140 501 new cases; 434.1 new cases per 100 000; 8% increase), Japan (111 601 new cases; 88.2 new cases per 100 000; 23% increase), and the Philippines (77 540 new cases; 70.8 new cases per 100 000; 28% increase).

The highest numbers of new deaths were reported from Viet Nam (2187 new deaths; 2.2 new deaths per 100 000; 13% increase), Malaysia (1839 new deaths; 5.7 new deaths per 100 000; 35% increase), and the Philippines (1235 new deaths; 1.1 new deaths per 100 000; 31% increase).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his opening remarks at the [media briefing on COVID-19 – 11 August 2021](#), the Director-General highlighted the following:
 - In October 2020, WHO shared [the results of the Solidarity Therapeutics Trial](#), which tested four treatments for COVID-19, involving almost 13,000 patients in 500 hospitals, in 30 countries
 - The next phase of the trial - Solidarity PLUS - will test three drugs: artesunate, a treatment for severe malaria; imatinib, a drug for certain cancers; and infliximab, a treatment for immune system disorders such as Crohn's disease. The trial involves thousands of researchers at more than 600 hospitals in 52 countries.

Updates and publications

- [Interim statement on heterologous priming for COVID-19 vaccines](#)
- [Interim statement on dose-sparing strategies for COVID-19 vaccines \(fractionated vaccine doses\)](#)
- [Interim statement on COVID-19 vaccine booster doses](#)

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

that information for this variant was received by WHO from official sources.

ation become available.

** Gamma was excluded for Bangladesh this week based on further information.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community).

Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] On 20 July, [Ecuador Ministry of Public Health \(MSP\)](#) revised their process of reporting on deaths. The country has now started reporting probable deaths and deaths in other facilities, as well as confirmed deaths, as part of their cumulative death count. Due to this change in reporting, an artificial inflation in last week's deaths in the Region has been observed. Thus, the decline in deaths observed this week should be interpreted carefully.

COVID-19 Weekly Epidemiological Update

Edition 52, published 10 August 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 8 August 2021

On 5 August, the cumulative number of COVID-19 cases globally surpassed 200 million, just six months after reaching 100 million cases. This week alone, over 4.2 million new cases and over 65 000 new deaths were reported, a slight increase as compared to the previous week. The largest proportionate increases in new cases were reported by the Region of the Americas (14%) and Western Pacific Region (19%), with 1.3 million and over 375 000 new cases reported, respectively. Additionally, a substantial increase (46%) in the number of new deaths was reported this week in the Western Pacific Region (Table 1). Of the 228 Member States and territories, 38 (17%) reported more than a 50% increase in new cases as compared to the previous week and 34 (15%) reported a more than a 50% increase in new deaths.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 8 August 2021**

**See [Annex 2: Data, table and figure notes](#)

The Regions reporting the highest weekly case and deaths incidence rates per 100 000 population remain the same as last week: the Regions of the Americas (136.5 new cases per 100 000 population; 14% increase) and Europe (108.6 new cases per 100 000 population; 7% decrease) reported the highest weekly incidence in cases; while the Regions of the Americas (1.9 per 100 000 population; 4% decrease), Europe (1.0 per 100 000

population; 16% increase) and South-East Asia (1.0 per 100 000 population; 6% decrease) reported the highest weekly incidence in deaths.

At the country level, the highest numbers of new cases were reported from the United States of America (734 354 new cases; 35% increase), India (278 631 new cases; 2% decrease), the Islamic Republic of Iran (248 102 new cases; 20% increase), Brazil (228 473 new cases; 8% decrease), and Indonesia (225 635 new cases; 18% decrease).

Globally, cases of the Alpha variant have been reported in 185 countries, territories or areas (hereafter countries), with three new countries reporting this Variant of Concern (VOC) since last week, while 136 countries (four new countries) have reported cases of the Beta variant; 81 countries (no new country) have reported cases of the Gamma variant; and 142 countries (seven new countries) have reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 8 August 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 396 284 (33%)	14%	78 619 744 (39%)	19 832 (30%)	-4%	2 030 101 (47%)
Europe	1 012 890 (24%)	-7%	61 214 530 (30%)	9 562 (15%)	16%	1 230 343 (29%)
South-East Asia	799 225 (19%)	-5%	39 177 502 (19%)	20 702 (32%)	-6%	590 988 (14%)
Eastern Mediterranean	499 655 (12%)	8%	13 095 783 (6%)	6 000 (9%)	8%	242 229 (6%)
Africa	181 019 (4%)	-1%	5 137 088 (3%)	4 743 (7%)	-2%	122 025 (3%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

For updates on VOCs and VOIs, and a list of Alerts for Further Monitoring, are available on the [WHO Tracking SARS-CoV-2 Variants website](#).

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of these COVID-19 Weekly Epidemiological Updates. Since the last detailed [update](#) on 20 July, new evidence has been published on the phenotypic characteristics of VOCs.

A case-control study conducted in Qatar¹ using a national database comparing outcomes of cases (defined as individuals with severe or critical COVID-19 or who progressed to death) and controls (individuals with asymptomatic or mild disease) found the odds of progressing to severe disease requiring acute-care hospitalization was 1.24 (95% CI 1.11-1.39) for cases infected with Beta compared to Alpha. The odds of cases progressing to critical disease requiring ICU admission was 1.49 (95%CI 1.13-1.97) for Beta compared to Alpha, and the odds of death were 1.57 (95% CI 1.03-2.43) for Beta compared to Alpha^{1(p)}.

An analysis of symptomatic², PCR positive cases aged 15 years or older in the United Kingdom (n=83 197) identified between 12 April and 27 June 2021 found that 1.2% (980/83 197) were possible reinfections. The adjusted odds ratio of reinfection with the Delta variant was 1.46 (95% CI 1.03-2.05) compared to the Alpha variant³.

A report on the first local transmission of the Delta SARS-CoV-2 variant in China⁴ described viral infection and transmission dynamics of 167 cases that were traced back to the index case. Daily sequential PCR testing of the quarantined subjects indicated that among those who became infected, the viral load of the first positive test of Delta infections was approximately 1000 times

higher than that of the original non-VOC strain, suggesting the potential for faster viral replication and increased infectiousness of the Delta variant during early stages of infection⁵.

Another report by Public Health England⁶ showed similar findings of high viral loads among breakthrough cases infected with Delta. However, the authors highlighted that the results may be influenced by test-seeking behaviour or by changes, such as age distribution of cases, which can also influence cycle threshold (Ct) values.

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility and secondary attack rate ⁷	Increased transmissibility ⁸	Increased transmissibility ⁹	Increased transmissibility and secondary attack rate ¹⁰ Similar transmissibility between vaccinated and unvaccinated individuals ^{11–13}
Disease severity	Increased risk of hospitalization ¹⁴ , possible increased risk of severity and mortality ¹⁵	Not confirmed, possible increased risk of in-hospital mortality ¹⁶	Not confirmed, possible increased risk of hospitalization ¹⁷	Increased risk of hospitalization ¹⁸
Risk of reinfection	Neutralizing activity retained ¹⁹ , risk of reinfection remains similar ²⁰	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²¹	Moderate reduction in neutralizing activity reported ²²	Reduction in neutralizing activity reported ^{23–25}
Impacts on diagnostics	Limited impact – S gene target failure (SGTF); no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed ²⁶	No impact on RT-PCR or Ag RDTs observed ²⁵	None reported to date	None reported to date

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

VE refers to vaccine effectiveness and vaccine efficacy. Summary VE*: indicates the general conclusions but only for the vaccines evaluated against the specific variant. Arrows generalize the magnitude of reduction in VE or neutralization: "↔" <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; "↓" 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; "↓↓" 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; "↓↓↓" ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When

more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used. “Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

The number of studies is shown as subscripts: vaccine effectiveness and neutralization studies informing this table can be found on the VIEW-hub Resources page (<https://view-hub.org/resources>). For vaccine effectiveness studies, see references noted with ‘#’ in the ‘COVID-19 Vaccine Effectiveness Results Summary Table’. For a list of all neutralization studies, see ‘COVID-19 Vaccine Neutralization Studies Table’.

References indicated by superscripts are vaccine efficacy studies informing this table and are included in the reference section below.

Additional notes on VOC impacts on vaccines

- All comparisons of results with and without VOC are within a given vaccine product.
- Studies presenting VOC-specific vaccine efficacy or effectiveness (VE) estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate for that product to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for severe disease (phase 3 RCT efficacy estimates against severe disease are used as comparator since a within study comparator is unavailable) and for infection (when phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection outcome even without a comparator if a very high VE estimate is reported against a VOC (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates for a product between different studies. In addition, the reductions summarized in the table represent VE point estimates and do not represent the uncertainty intervals around these estimates which vary substantially across studies. The reductions in VE noted should be interpreted with these limitations in mind.

Table 3 presents the impact of variants on product specific vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE in the setting of VOCs compared to VE in non-VOC settings. Of note, reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of $\sim 85\%$. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean substantial protection, as is the case for AstraZeneca -Vaxzevria.

Since the [20 July update](#), results from an ongoing randomized clinical trial evaluating the 6-month efficacy of Pfizer BioNTech-Comirnaty against SARS-CoV-2 infection (symptomatic + asymptomatic) in persons ≥ 12 years old reports an overall vaccine efficacy against infection and against severe disease ≥ 7 days post second dose of 91% (95% CI: 89.0-93.2%) and 96.7% (95% CI: 80.3-99.9%), respectively, across 152 participating sites in 6 countries. The authors also estimated VE against the Beta variant in South Africa and found 2 doses of Pfizer BioNTech-Comirnaty prevented 100% (95% CI: 53.5-100.0%) of SARS-CoV-2 infections ≥ 7 days post second dose, though confidence intervals are wide.³² These results have not yet been peer-reviewed.

A second study (not yet peer-reviewed) estimated the effectiveness of Pfizer BioNTech-Comirnaty against infection with the Beta variant among residents of long-term care facilities (LTCFs) in France. The authors describe two outbreaks associated with the Beta variant among LTCFs in which more than 70% of residents had received both doses of the vaccine. VE in this population against any SARS-CoV-2 infection ≥ 7 days after receipt of the second dose was 49% (95% CI: 14-69%). VE against severe disease remained high at 86% (95% CI: 67-94%).³⁴

Another study (not yet peer-reviewed) evaluated the real-world effectiveness of mRNA (Moderna-mRNA-1273 and Pfizer BioNTech-Comirnaty) vaccines among health care workers in Canada, where the interval between doses was 16 weeks. Most participants (88%) included in the analysis received Pfizer BioNTech-Comirnaty vaccine. Using a test-negative design, the study found that a single dose of mRNA vaccine had lower effectiveness against symptomatic COVID-19 due to the Alpha variant compared to non-VOC strains: 60% (95%CI: 53.6-65.5%) vs. 77.0% (95%CI: 72.6-80.7%), but no substantive difference in two-dose recipients: 92.6% (95%CI: 87.1%-95.8%) vs. 86.5% (95%CI: 56.8-95.8%).³⁵

A fourth study (not yet peer-reviewed), also using a test-negative case-control design, evaluated the effectiveness of AstraZeneca-Vaxzevria in adults ≥ 60 years in Brazil in a setting of high prevalence of the Gamma variant. Single dose VE estimates against SARS-CoV-2 infection, hospitalization, and death ≥ 28 days after immunization were 33.4% (95% CI: 26.4 to 39.7%), 55.1% (95% CI: 46.6 to 62.2%), and 61.8% (95% CI: 48.9 to 71.4%), respectively. Beginning at 14 days after receipt of the second dose, respective VE estimates increased to 77.9% (95% CI: 69.2 to 84.2%), 87.6% (95% CI: 78.2 to 92.9%), and 93.6% (95% CI: 81.9 to 97.7%).³⁶

Eight recent studies have assessed the impact of the Delta variant on COVID-19 vaccine performance. Three evaluated vaccine effectiveness. A study from India (not yet peer-reviewed) assessed the effectiveness of AstraZeneca-Vaxzevria vaccine at preventing SARS-CoV-2 infection and severe COVID-19 disease in a setting with high prevalence of the Delta variant. Two doses of the vaccine were 63.1% (95%CI: 51.5-72.1%) and 81.5% (95%CI: 9.9- 99.0) effective at preventing infection and moderate-severe disease, respectively. Single dose VE against infection (46.2%, 95%CI: 31.6, 57.7) was lower than 2 dose VE, while single dose VE against moderate-severe disease (79.2%, 95%CI: 46.1-94.0%) was similar to that of 2 doses. While this study was conducted during a time of high transmission of the Delta variant, it is noteworthy that viral sequencing and lineage determination were available from only a small subset of positive cases (4.4%); of these samples 90% were the Delta variant.³⁷

A second study, from the United States, evaluated cases occurring between April and June 2021 in Mesa County, Colorado, where cases of the Delta variant had increased rapidly. The fraction of cases who were fully vaccinated with any vaccine was evaluated in Mesa county and compared to the rest of the state which experienced a slower increase in the proportion of the Delta variant cases among new infections. Among COVID-19 cases aged ≥ 65 years in Mesa county, 27.5% were fully vaccinated compared to 17.4% in other Colorado counties. The authors report a crude VE of 78% (95% CI: 71%–84%) against symptomatic infection for a 2-week period ending June 5 in Mesa County and 89% (95% CI = 88%–91%) for the rest of the state; during this time Delta made up close to 100% of sequenced samples in Mesa compared to $\sim 50\%$ for all other counties.³⁸ A third study (not yet peer reviewed), from the UK, estimated VE of any COVID-19 vaccine against infection and symptomatic disease to be 49% (95%: 22-67%) and 59% (95% CI: 23-78%), respectively, among adults 18 to 64 years during the period from 24 June to 12 July 2021 when the Delta variant was highly prevalent. These estimates were reduced compared to the period from 20 May to 7 June 2021 characterized by lower Delta prevalence and VE estimates against infection and symptomatic disease of 64% (95% CI: 11%-85%) and 83% (95% CI: 19-97%), respectively. VE against severe disease was not evaluated in this study.³⁹

The authors of this UK study also found reduced viral load (higher cycle threshold values) among vaccinated COVID-19 cases compared to unvaccinated cases during the period of high Delta prevalence. A study of Delta breakthrough infections in Singapore (not yet peer reviewed) found that those who were fully vaccinated with an mRNA vaccine had similar viral loads to those who were infected with Delta but unvaccinated; however, the viral loads were found to decrease faster among those who were vaccinated. The authors also reported that fully vaccinated individuals experienced less severe illness than unvaccinated individuals.⁴⁰ Two additional studies from the United States of America (one not yet peer reviewed) also found no difference in viral load among cases who had been vaccinated with any vaccine and unvaccinated cases during a time when there was a high prevalence of the Delta variant.^{11,13}

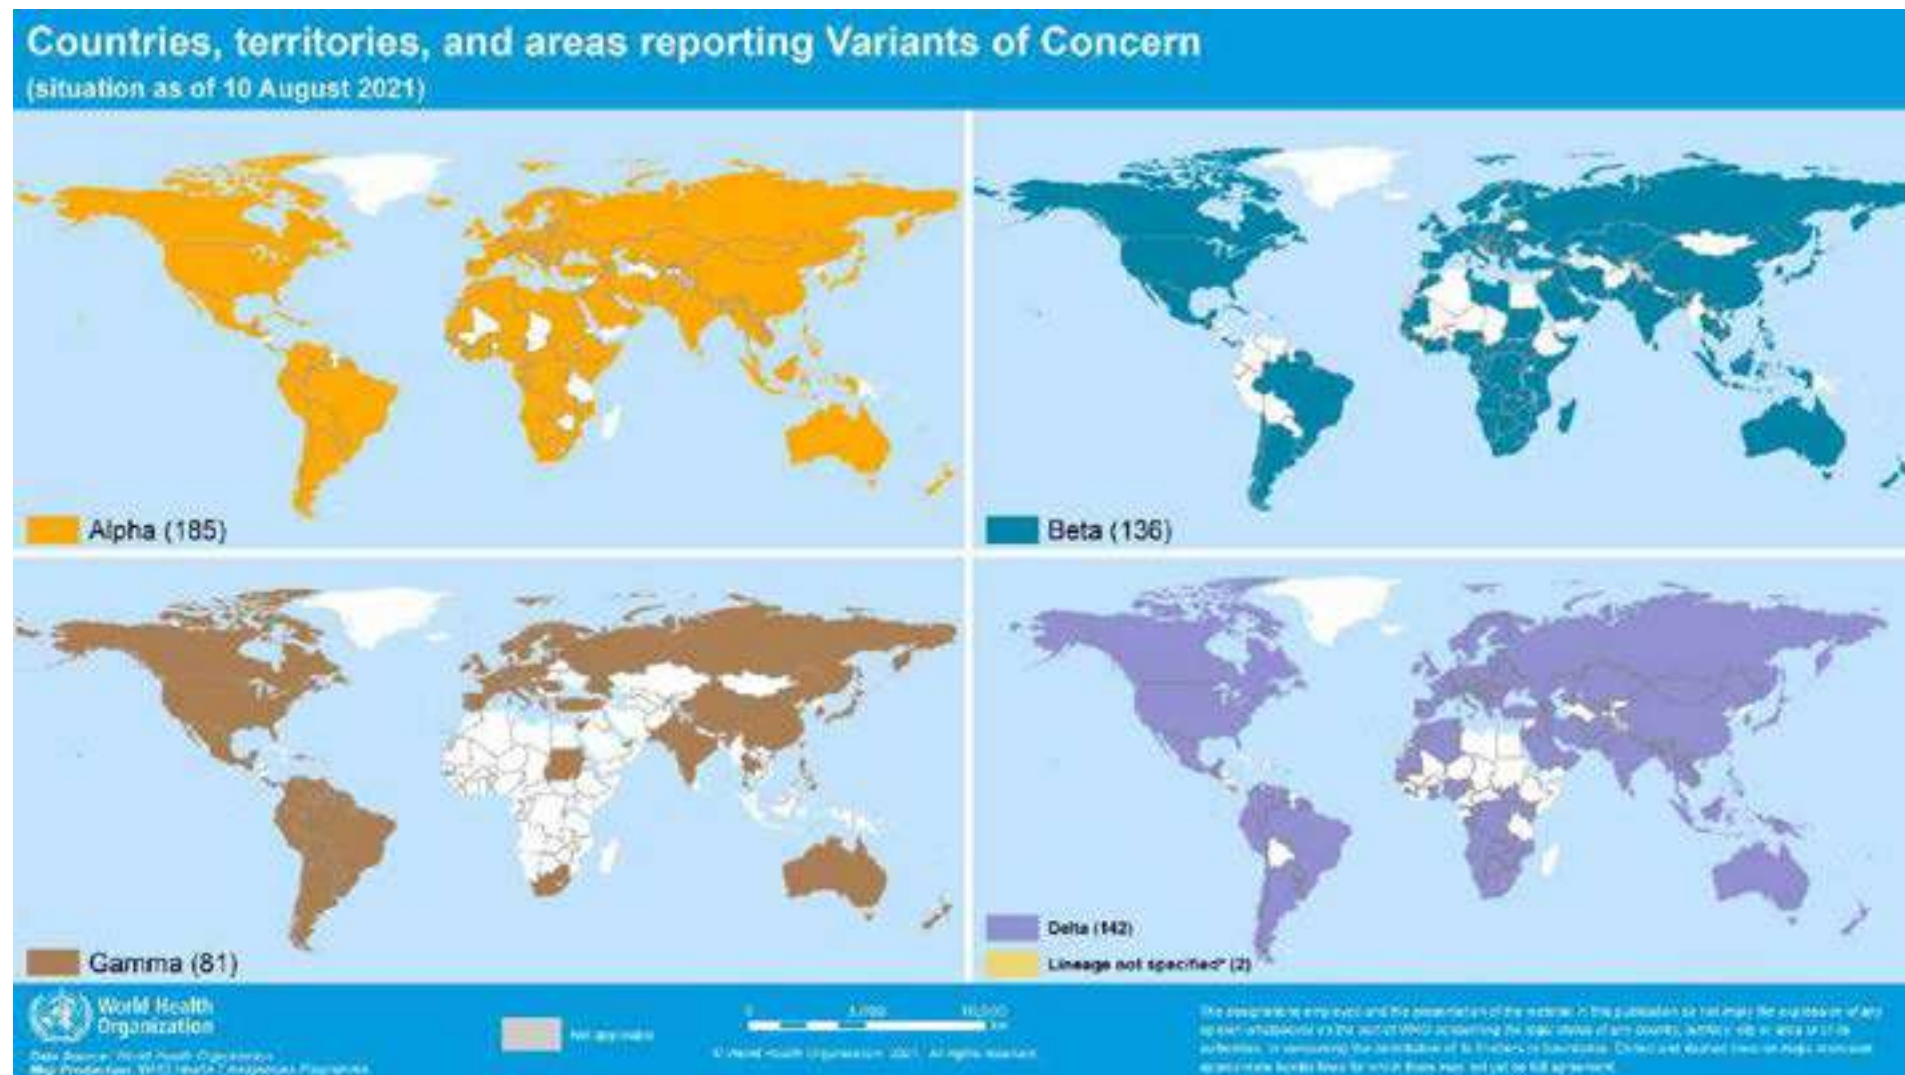

Two studies from Israel (both not yet peer-reviewed) assessed the duration of protection by the Pfizer BioNTech-Comirnaty vaccine. The first study compared the rate of breakthrough infection during June and July 2021, a period during which the Delta variant was dominant, between individuals who received 2 doses of the vaccine in winter 2021 to individuals who received two doses of the vaccine in the spring, adjusting for confounders. The authors report that persons vaccinated between January and February 2021 had a 53% (95% CI: 40-68%) increased risk of breakthrough infection in June and July compared to individuals vaccinated between March and April 2021.⁴¹ The second study, conducted during a time of high Delta

transmission (Delta infections accounted for 93% of a small subset of cases which were sequenced) found an increased odds (odds ratio: 2.1, 95% CI: 1.7-2.5) of SARS-CoV-2 infection among persons vaccinated at least 146 days before their positive test results compared to individuals who were vaccinated less than 146 days prior to becoming infected.⁴² These preliminary findings may suggest a decrease in long-term protection of the vaccine or decreased effectiveness of the vaccine against the Delta variant or a combination of these factors. No unvaccinated persons were included in these two studies; thus vaccine effectiveness was not evaluated.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 10 August 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews — Epidemiological week 2 – 8 Aug 2021

African Region

The Region reported relatively similar numbers of weekly cases and deaths as the previous week, with just over 181 000 new cases (-1%) and over 4700 new deaths (-2%) reported this week. After cases peaked in June 2021, the Region has experienced a decrease in weekly reported cases since the middle of July, largely driven by declines observed in South Africa. However, over the past two weeks the rate of decline has slowed and nearly half of the countries in the Region (24; 49%) are now reporting increasing trends.

Most countries in the Region (31; 63%) showed decreasing trends in the number of new deaths reported. This decline has been driven by decreases in deaths reported from Namibia (-51%), Uganda (-42%), Zimbabwe (-39%) and Zambia (-39%). Overall, the highest numbers of new cases were reported from South Africa (76 034 new cases; 128.2 new cases per 100 000 population; 4% decrease), Botswana (15 884 new cases; 675.4 new cases per 100 000; 76% increase), and Mozambique (9771 new cases; 31.3 new cases per 100 000; 26% decrease). The highest numbers of new deaths were reported from South Africa (2610 new deaths; 4.4 new deaths per 100 000 population; 3% increase), Zimbabwe (294 new deaths; 2.0 new deaths per 100 000; 39% decrease), and Algeria (233 new deaths; 0.5 new deaths per 100 000; 10% increase).

Updates from the [African Region](#)

Region of the Americas

This week, the Region of the Americas reported an increase of 14% in new cases as compared to the previous week, with just under 1.4 million new cases reported. The Region showed a slight decrease in the number of weekly deaths as compared to the previous week, with nearly 20 000 new deaths reported (4% decrease compared with the previous week).

The increase in weekly cases is mainly driven by Peru (a 64% increase), and the United States of America (35%). The declines in mortality reported by the Region in recent weeks have been mainly driven by Ecuador* (-81%), Argentina (-27%), Colombia (-26%) and Brazil (-12%). Overall, the highest numbers of new cases were reported from the United States of America (734 354 new cases; 221.9 new cases per 100 000; 35% increase), Brazil (228 473 new cases; 107.5 new cases per 100 000; 8% decrease), and Mexico (114 783 new cases; 89.0 new cases per 100 000; 11% increase). The highest numbers of new deaths were reported from Brazil (6302 new deaths; 3.0 new deaths per 100 000; 11% decrease), the United States of America (3391 new deaths; 1.0 new deaths per 100 000; 38% increase), and Mexico (3277 new deaths; 2.5 new deaths per 100 000; 31% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported just under half a million new cases and over 6000 new deaths, increases of 8% as compared to the previous week. The Region continued to report the highest weekly number of cases since the beginning of the pandemic for the second consecutive week. Almost half of the countries in the Region (10 of 22) have reported an increase in cases as compared to the previous week, mainly driven by the surge reported by the Islamic Republic of Iran (20%) and Morocco (31%). The highest numbers of new cases were reported from the Islamic Republic of Iran (248 102 new cases; 295.4 new cases per 100 000), Iraq (77 764 new cases; 193.3 new cases per 100 000; 6% decrease), and Morocco (63 764 new cases; 172.8 new cases per 100 000).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (2843 new deaths; 3.4 new deaths per 100 000; 36% increase), Tunisia (951 new deaths; 8.0 new deaths per 100 000; 24% decrease), and Iraq (489 new deaths; 1.2 new deaths per 100 000; 15% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

While the European Region reported a 7% decrease in the number of weekly cases as compared to the previous week, it still reported over one million new cases with an increasing trend in a number of countries in South-East Europe including North Macedonia, Kosovo and Albania. The number of weekly deaths increased by 16% as compared to the previous week, with over 9500 new deaths reported, and Estonia, Kosovo and Romania reporting sharp increases in new deaths. The highest numbers of new cases were reported from the United Kingdom (185 724 new cases; 273.6 new cases per 100 000; similar to the previous week), Russian Federation (159 073 new cases; 109.0 new cases per 100 000; similar to the previous week), and Turkey (144 839 new cases; 171.7 new cases per 100 000; a 4% increase).

The highest numbers of new deaths were reported from the Russian Federation (5529 new deaths; 3.8 new deaths per 100 000; similar to the previous week), Kazakhstan (832 new deaths; 4.4 new deaths per 100 000; 25% decrease) and Turkey (649 new deaths; <1 new deaths per 100 000; 43% increase).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 799 000 new cases, a 5% decrease as compared to the previous week, however, several countries in the Region continue to report increasing trends, including Sri Lanka and Thailand (26% and 20% increases, respectively). Case incidence in the region peaked in early May and has since largely plateaued over the past month. This is largely due to cases in India remaining stable, and consistent decreases in Indonesia and Myanmar over the past month. Following a steep increase in the mortality rate in the Region, this is the first time in seven weeks that a decline in the number of new weekly deaths has been reported; a trend largely driven by declines in the Maldives and Myanmar this week. Large increases in weekly deaths were reported in several countries including Sri Lanka, Nepal and Thailand (47%, 35% and 30% increases, respectively). The highest numbers of new cases were reported from India (278 631 new cases; 20.2 new cases per 100 000; 2% decrease), Indonesia (225 635 new cases; 82.5 new cases per 100 000; 18% decrease), and Thailand (141 191 new cases; 202.3 new cases per 100 000; 20% increase).

The highest numbers of new deaths were reported from Indonesia (11 373 new deaths; 4.2 new deaths per 100 000; 9% decrease), India (3511 new deaths; 0.3 new deaths per 100 000; 8% decrease), and Myanmar (2045 new deaths; 3.8 new deaths per 100 000; 22% decrease).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 375 000 new cases and over 4600 new deaths, increases of 19% and a 46%, respectively, as compared to the previous week. This increasing trend in both cases and deaths has been observed for nearly two months and is largely due to continued increases in case incidence in Japan, Philippines and Malaysia, although nearly half of the countries in the region are reporting rising case numbers (11 of 24; 46%). Similarly, the number of reported deaths has also been climbing over the past six weeks with a third (8 of 24; 33%) of the region's countries reporting an increase in deaths in the past week.

The highest numbers of new cases were reported from Malaysia (130 580 new cases; 403.4 new cases per 100 000; 12% increase), Japan (90 958 new cases; 71.9 new cases per 100 000; 51% increase), and the Philippines (60 373 new cases; 55.1 new cases per 100 000; 32% increase). The highest numbers of new deaths were reported from Viet Nam (1944 new deaths; 2.0 new deaths per 100 000; 108% increase), Malaysia (1365 new deaths; 4.2 new deaths per 100 000; 22% increase), and the Philippines (946 new deaths; 0.9 new deaths per 100 000; 25% increase).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his opening remarks at the [media briefing on COVID-19 - 4 August 2021](#), the Director-General called for a moratorium on booster shots until at least the end of September to enable at least 10% of the population of every country to be vaccinated.
- In his remarks at the [1st International Forum on Vaccine Cooperation - 5 August 2021](#), the Director-General quantified the WHO's global targets for vaccines against COVID-19: vaccinate at least 10% of the population of every country by September, at least 40% by the end of the year, and 70% of the world's population by mid-next year. With more than 11 billion doses of vaccine needed to reach these critical milestones.
- In his opening remarks at [the Member State Information Session on COVID-19 - 5 August 2021](#), the Director-General highlighted:
 - The WHO Strategic Preparedness and Response Plan for 2021 faces a funding shortfall of US\$900 million, less than half of what is needed. Of the funds received, nearly all of them are earmarked and not flexible to sustain urgent priorities for vaccination, surveillance and response in countries experiencing surges in cases based on emerging needs.
 - In addition, the Access to COVID-19 Tools Accelerator is launching the Rapid ACT-Accelerator Delta Response, or RADAR, issuing an urgent call for US\$7.7 billion for tests, treatments and vaccines.
 - In parallel, WHO will need \$3.8 billion in additional financing this year for COVAX to exercise its options to purchase vaccines for 2022.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

from official sources.

ation become available.

** Gamma was excluded for Bangladesh this week based on further information.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] On 20 July, [Ecuador Ministry of Public Health \(MSP\)](#) revised their process of reporting on deaths. The country has now started reporting probable deaths and deaths in other facilities, as well as confirmed deaths, as part of their cumulative death count. Due to this change in reporting, an artificial inflation in last week's deaths in the Region has been observed. Thus, the decline in deaths observed this week should be interpreted carefully.

COVID-19 Weekly Epidemiological Update

Edition 51, published 3 August 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 1 August 2021

The global number of new cases has been increasing for more than a month, with over 4 million cases reported in the past week (26 July to 1 August 2021) (Figure 1). This increasing trend is largely attributed to substantial increases in the Eastern Mediterranean and the Western Pacific Regions which reported 37% and 33% increases respectively as compared to the previous week, while the South-East Asia Region reported a 9% increase (Table 1); the other three Regions reported similar weekly case incidence or a slight decrease as compared to the previous week. Overall, the number of deaths reported this week decreased by 8% as compared to the previous week, with over 64 000 deaths reported. However, the Western Pacific and Eastern Mediterranean Regions showed a sharp increase in new deaths as compared to the previous week, reporting 48% and 31% increases, respectively. The other four Regions reported a similar number of weekly deaths as compared to the previous week, with the exception of the Region of the Americas which reported a 29% decrease. The cumulative number of cases reported globally is now nearly 197 million and the number of cumulative deaths is 4.2 million. If these trends continue, the cumulative number of cases reported globally could exceed 200 million by next week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 3 August 2021**

**See [Annex 2: Data, table and figure notes](#)

The Regions with the highest weekly case and deaths incidence rates per 100 000 population remain the same as last week: the Regions of the Americas (123.3 new cases per 100 000 population) and Europe (118.4 new cases per 100 000 population) reported the highest weekly case incidence while the Americas and South-East Asia Regions reported the highest weekly incidence in deaths, 2.0 and 1.1 new deaths per 100 000 population, respectively.

At the country level, the highest numbers of new cases in the past week were reported by the United States of America (543 420 new cases; 9% increase), India (283 923 new cases; 7% increase), Indonesia (273 891 new cases; 5% decrease), Brazil (247 830 new cases; 24% decrease), and the Islamic Republic of Iran (206 722 new cases; 27% increase).

Globally, cases of the Alpha variant have been reported in 182 countries, territories or areas (hereafter countries), while 132 countries (one new country) have reported cases of the Beta variant; 81 countries (one new country) have reported cases of the Gamma variant; and 135 countries (three new countries) have reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 3 August 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 225 408 (30%)	-3%	77 221 387 (39%)	20 590 (32%)	-29%	2 010 183 (48%)
Europe	1 004 722 (25%)	-9%	60 109 964 (30%)	8 024 (12%)	-2%	1 220 491 (29%)
South-East Asia	841 753 (21%)	9%	38 378 277 (19%)	22 010 (34%)	3%	570 286 (14%)
Eastern Mediterranean	463 090 (11%)	37%	12 596 128 (6%)	5 553 (9%)	31%	236 229 (6%)
Africa	182 067 (5%)	-1%	4 955 648 (3%)	4 853 (8%)	-2%	117 282 (3%)
Western Pacific	316 796 (8%)	33%	4 525 949 (2%)	3 186 (5%)	48%	65 094 (2%)
Global	4 033 836 (100%)	3%	197 788 117 (100%)	64 216 (100%)	-8%	4 219 578 (100%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As these risks evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website).

National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

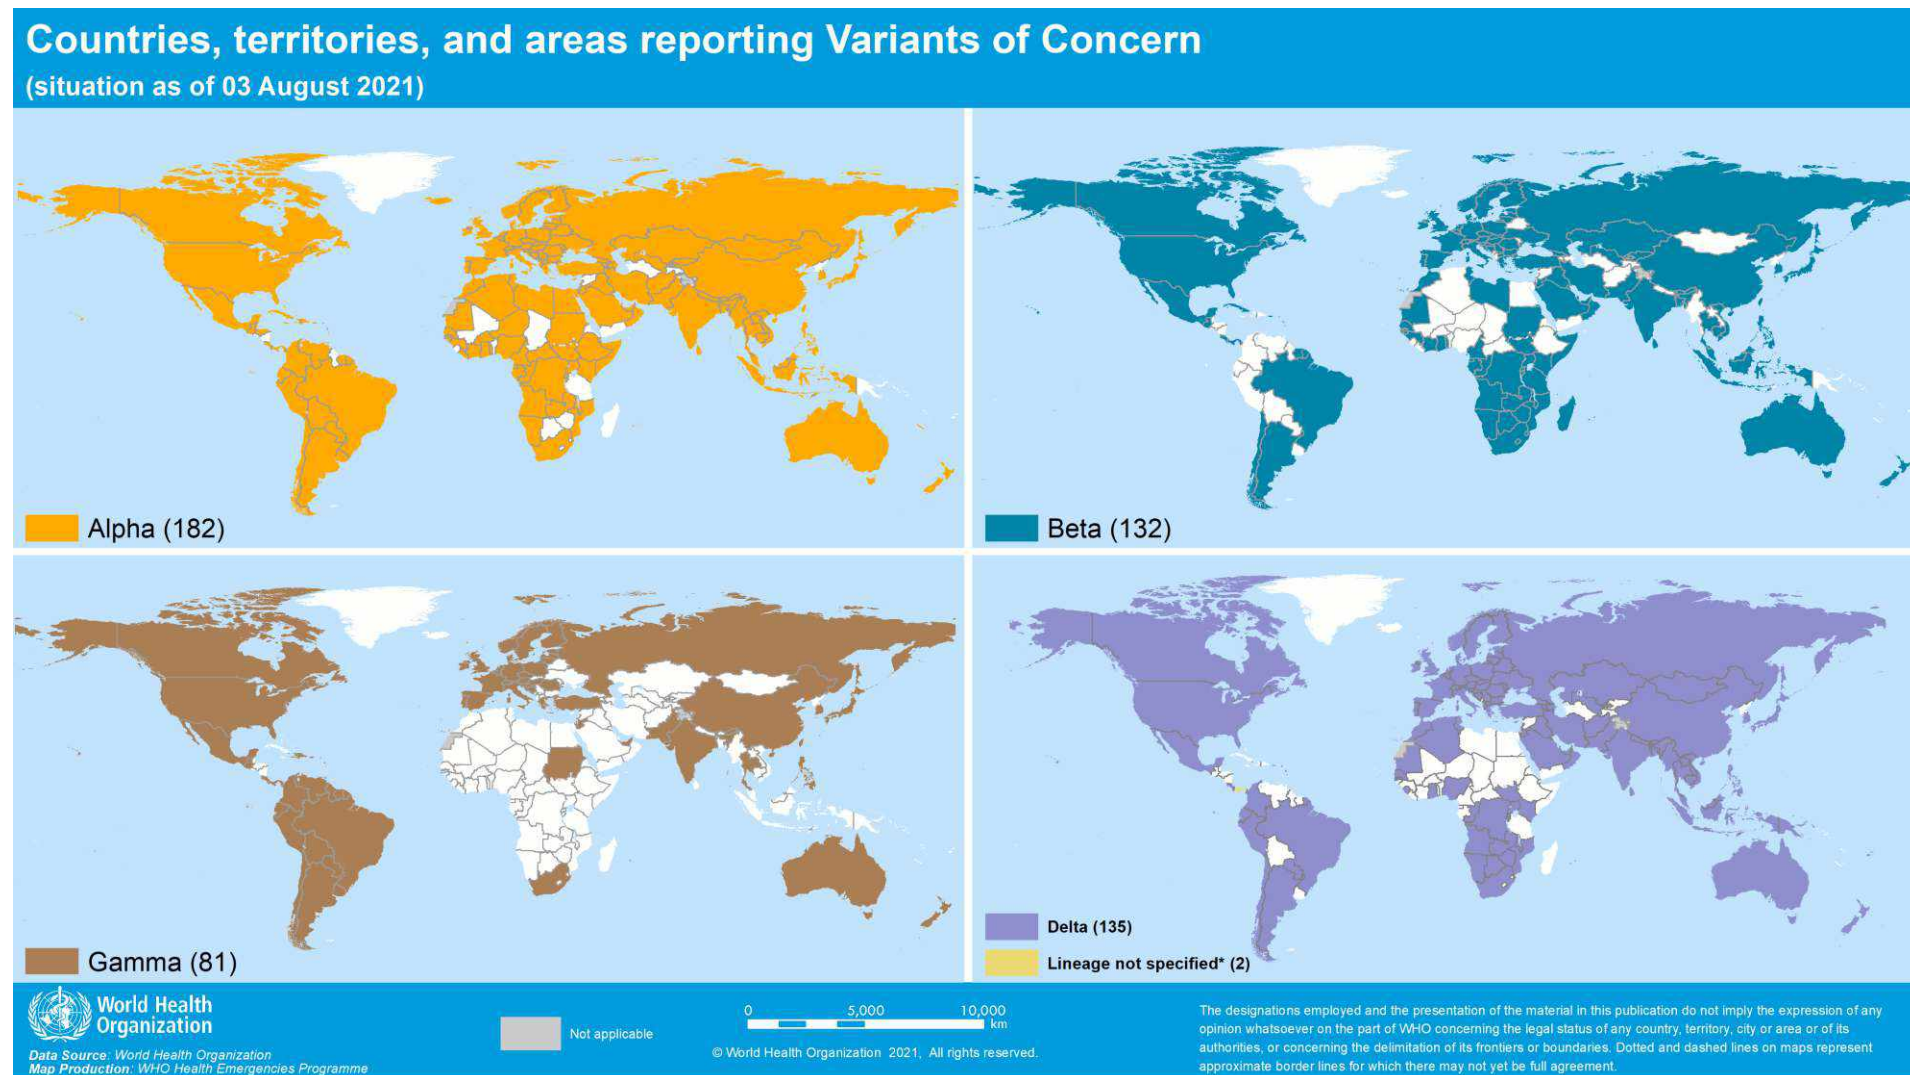

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 4, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on thorough risk assessments conducted systematically and routinely.

Figure 4 . Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 3 August 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews - Epidemiological week 26 July - 1 Aug 2021

African Region

The Region reported relatively similar numbers of weekly cases and deaths as the previous week, with just over 182 000 new cases and over 4800 new deaths reported this week. The overall decrease in weekly cases reported in the Region since the middle of July has been largely driven by declines observed in South Africa. In contrast, many other countries in the Region continue to report increasing case incidence. Similarly, for mortality, the trend in the region is largely driven by a decline in new weekly deaths reported by South Africa.

The highest numbers of new cases were reported from South Africa (79 349 new cases; 133.8 new cases per 100 000 population; 6% decrease), Mozambique (13 268 new cases; 42.5 new cases per 100 000; 25% increase), and Zimbabwe (11 583 new cases; 77.9 new cases per 100 000; 21% decrease). The highest numbers of new deaths were reported from South Africa (2525 new deaths; 4.3 new deaths per 100 000 population; 10% decrease), Zimbabwe (482 new deaths; 3.2 new deaths per 100 000; 4% increase), and Namibia (284 new deaths; 11.2 new deaths per 100 000; 12% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.2 million new cases and over 20 000 new deaths in the past week. While the number of cases reported was similar to the previous week, the number of weekly deaths decreased by 29%. This is largely due to a sharp decline in deaths in Ecuador this week as compared to last week (19-25 July) when the country reported a sharp increase in new weekly deaths. This increase was mainly due to a change in the definition of a COVID-19 death in Ecuador^[2] that had artificially inflated the death count for the region in the previous week.

The highest numbers of new cases were reported from the United States of America (543 420 new cases; 164.2 new cases per 100 000; 9% increase), Brazil (247 830 new cases; 116.6 new cases per 100 000; 24% decrease), and Mexico (103 283 new cases; 80.1 new cases per 100 000; 23% increase). The highest numbers of new deaths were reported from Brazil (7120 new deaths; 3.3 new deaths per 100 000; 10% decrease), Mexico (2502 new deaths; 1.9 new deaths per 100 000; 29% increase), and the United States of America (2455 new deaths; <1 new death per 100 000; 32% increase).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 463 000 new cases and over 5500 new deaths, increases of 37% and 31%, respectively, as compared to the previous week. This week, the Region reported the highest weekly number of cases since the beginning of the pandemic. The increase in cases and deaths is mainly driven by an increase in new cases reported by the Islamic Republic of Iran. The highest numbers of new cases were reported from the Islamic Republic of Iran (206 722 new cases; 246.1 new cases per 100 000; 27% increase), Iraq (83 098 new cases; 206.6 new cases per 100 000; 37% increase), and Morocco (48 366 new cases; 131.0 new cases per 100 000; 146% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (2098 new deaths; 2.5 new deaths per 100 000; 34% increase), Tunisia (1258 new deaths; 10.6 new deaths per 100 000; 5% increase), and Iraq (425 new deaths; 1.1 new deaths per 100 000; 4% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

After more than a month of reporting increases in the number of weekly cases and deaths, the Region reported a 9% decrease in weekly cases as compared to the previous week, with just over one million new cases reported. The number of weekly reported deaths was similar to the previous week, with just over 8 000 new deaths reported. The highest numbers of new cases were reported from the United Kingdom (187 268 new cases; 275.9 new cases per 100 000; 34% decrease), the Russian Federation (162 136 new cases; 111.1 new cases per 100 000; 4% decrease), and Turkey (139 667 new cases; 165.6 new cases per 100 000; 114% increase). The observed decrease in newly reported cases in the Region has been mainly driven by decline in new cases from Spain, where cases dropped from 181 322 cases reported during the past week to 90 332 this week, and from the United Kingdom where cases dropped from 282 920 in the previous week to 187 268 this week.

The highest numbers of new deaths were reported from the Russian Federation (5478 new deaths; 3.8 new deaths per 100 000; no change compared to last week), the United Kingdom (524 new deaths; 0.8 new deaths per 100 000; 17% increase), and Turkey (453 new deaths; <1 new death per 100 000; 16% increase).

Updates from the [European Region](#)

South-East Asia Region

The Region reported a 9% increase in new cases as compared to the previous week (over 841 000 cases), while the number of weekly deaths remained similar to the previous week (22 000 deaths). The highest numbers of new cases were reported from India (283 923 new cases; 20.6 new cases per 100 000; 7% increase), Indonesia (273 891 new cases; 100.1 new cases per 100 000; 5% decrease), and Thailand (118 012 new cases; 169.1 new cases per 100 000; 26% increase). Cases from these three countries accounted for 80% of new cases being reported from the Region.

The highest numbers of new deaths were reported from Indonesia (12 444 new deaths; 4.5 new deaths per 100 000; 28% increase), India (3800 new deaths; <1 new death per 100 000; 45% decrease), and Myanmar (2620 new deaths; 4.8 new deaths per 100 000; 24% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Cases have continued to increase for over a month. This week, the Region reported nearly 317 000 new cases and nearly 3200 new deaths, increases of 33% and 48% respectively, as compared to the previous week. The increase in newly reported cases has been mainly driven by Japan and Malaysia while the increase in newly reported deaths is largely driven by Viet Nam as well as Malaysia, where Viet Nam reported over 500% increase when compared to last week while Malaysia reported an 8% increase, with over 1100 new deaths reported. Overall, the majority of countries in the Region (15 out of 24; 62.5%) have reported an increasing trend in newly reported cases, as compared to the previous week.

The highest numbers of new cases were reported from Malaysia (116 879 new cases; 361.1 new cases per 100 000; 29% increase), Japan (60 157 new cases; 47.6 new cases per 100 000; 121% increase), and Viet Nam (55 147 new cases; 56.7 new cases per 100 000; 26% increase). The highest numbers of new deaths were reported from Malaysia (1122 new deaths; 3.5 new deaths per 100 000; 8% increase), Viet Nam (936 new deaths; 1.0 new deaths per 100 000; 546% increase), and the Philippines (758 new deaths; <1 new death per 100 000; 42% increase).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his opening remarks at the [media briefing on COVID-19 – 30 July 2021](#), the Director-General highlighted the following:
 - In response to the Delta surge, the Access to COVID-19 Tools Accelerator is launching the Rapid ACT-Accelerator Delta Response, or RADAR, issuing an urgent call for 7.7 billion U.S. dollars for tests, treatments and vaccines.
 - WHO's goal remains to support every country to vaccinate at least 10% of its population by the end of September, at least 40% by the end of this year, and 70% by the middle of next year.

Updates and publications

- [Holding gatherings during the COVID-19 pandemic: WHO policy brief, 2 August 2021](#)

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

from official sources.

ation become available.

** Gamma was excluded for Bangladesh this week based on further information.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

^[2] On 20 July, [Ecuador Ministry of Public Health \(MSP\)](#) revised their process of reporting on deaths. The country has now started reporting probable deaths and deaths in other facilities, as well as confirmed deaths, as part of their cumulative death count. Due to this change in reporting, an artificial inflation in last week's deaths in the Region has been observed. Thus, the decline in deaths observed this week should be interpreted carefully.

Global overview

Data as of 25 July 2021

The global number of new cases reported last week (19-25 July 2021) was over 3.8 million, an 8% increase as compared to the previous week (Figure 1); an average of around 540 000 cases were reported each day over the past week as compared to 490 000 cases reported daily the week before. This trend is largely attributed to substantial increases in the Americas and Western Pacific Regions. The number of deaths reported this week increased sharply with over 69 000 deaths, a 21% increase when compared to the previous week; the greatest number of new deaths were reported from the Americas and South-East Asia Regions. The cumulative number of cases reported globally is now nearly 194 million and the number of cumulative deaths exceeds 4 million. If these trends continue, the cumulative number of cases reported globally could exceed 200 million in the next two weeks. Last week, three WHO Regions - the Americas, Europe and South-East Asia reported an increase in case incidence. The Region of the Americas reported the largest increase in case incidence as compared to the previous week, followed by the Western Pacific Region (30% and 25%, respectively) (Table 1). The South-East Asia Region also reported an increase in new cases, albeit at a much lower rate of 3%, when compared to the previous week. The number of new deaths increased in all regions apart from the European Region where it remained similar to the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 25 July 2021**

**See [Annex 2: Data, table and figure notes](#)

The highest weekly case incidence rates per 100 000 population were reported by the Americas and European Regions, which reported 123.3 and 108.3 new cases per 100 000 population, respectively. The highest numbers of deaths per 100 000 population over the past week were observed in the Americas and South-East Asia Regions which reported 2.8 and 1.1 new deaths per 100 000 population, respectively.

Over the past week, the highest numbers of new cases were reported from the United States of America (500 332 new cases; 131% increase), Brazil (324 334 new cases; 13% increase), Indonesia (289 029 new cases; 17% decrease), the United Kingdom (282 920 new cases; 5% decrease), and India (265 836 new cases; similar to the previous week).

Globally, cases of the Alpha variant have been reported in 182 countries, territories or areas (hereafter countries; two new countries in the past week), while 131 countries (two new countries) have reported cases of the Beta variant; 81 countries (three new countries) have reported cases of the Gamma variant; and 132 countries (eight new countries) have reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 25 July 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 260 598 (33%)	30%	75 995 514 (39%)	28 938 (42%)	29%	1 989 575 (48%)
Europe	1 010 270 (27%)	3%	59 009 652 (30%)	7 545 (11%)	-1%	1 211 783 (29%)
South-East Asia	775 618 (20%)	-7%	37 536 524 (19%)	21 334 (31%)	30%	548 276 (13%)
Eastern Mediterranean	338 605 (9%)	-4%	12 133 038 (6%)	4 225 (6%)	8%	230 676 (6%)
Africa	184 361 (5%)	-9%	4 773 581 (2%)	4 931 (7%)	2%	112 429 (3%)
Western Pacific	238 487 (6%)	25%	4 208 652 (2%)	2 159 (3%)	3%	61 908 (1%)
Global	3 807 939 (100%)	8%	193 657 725 (100%)	69 132 (100%)	21%	4 154 660 (100%)

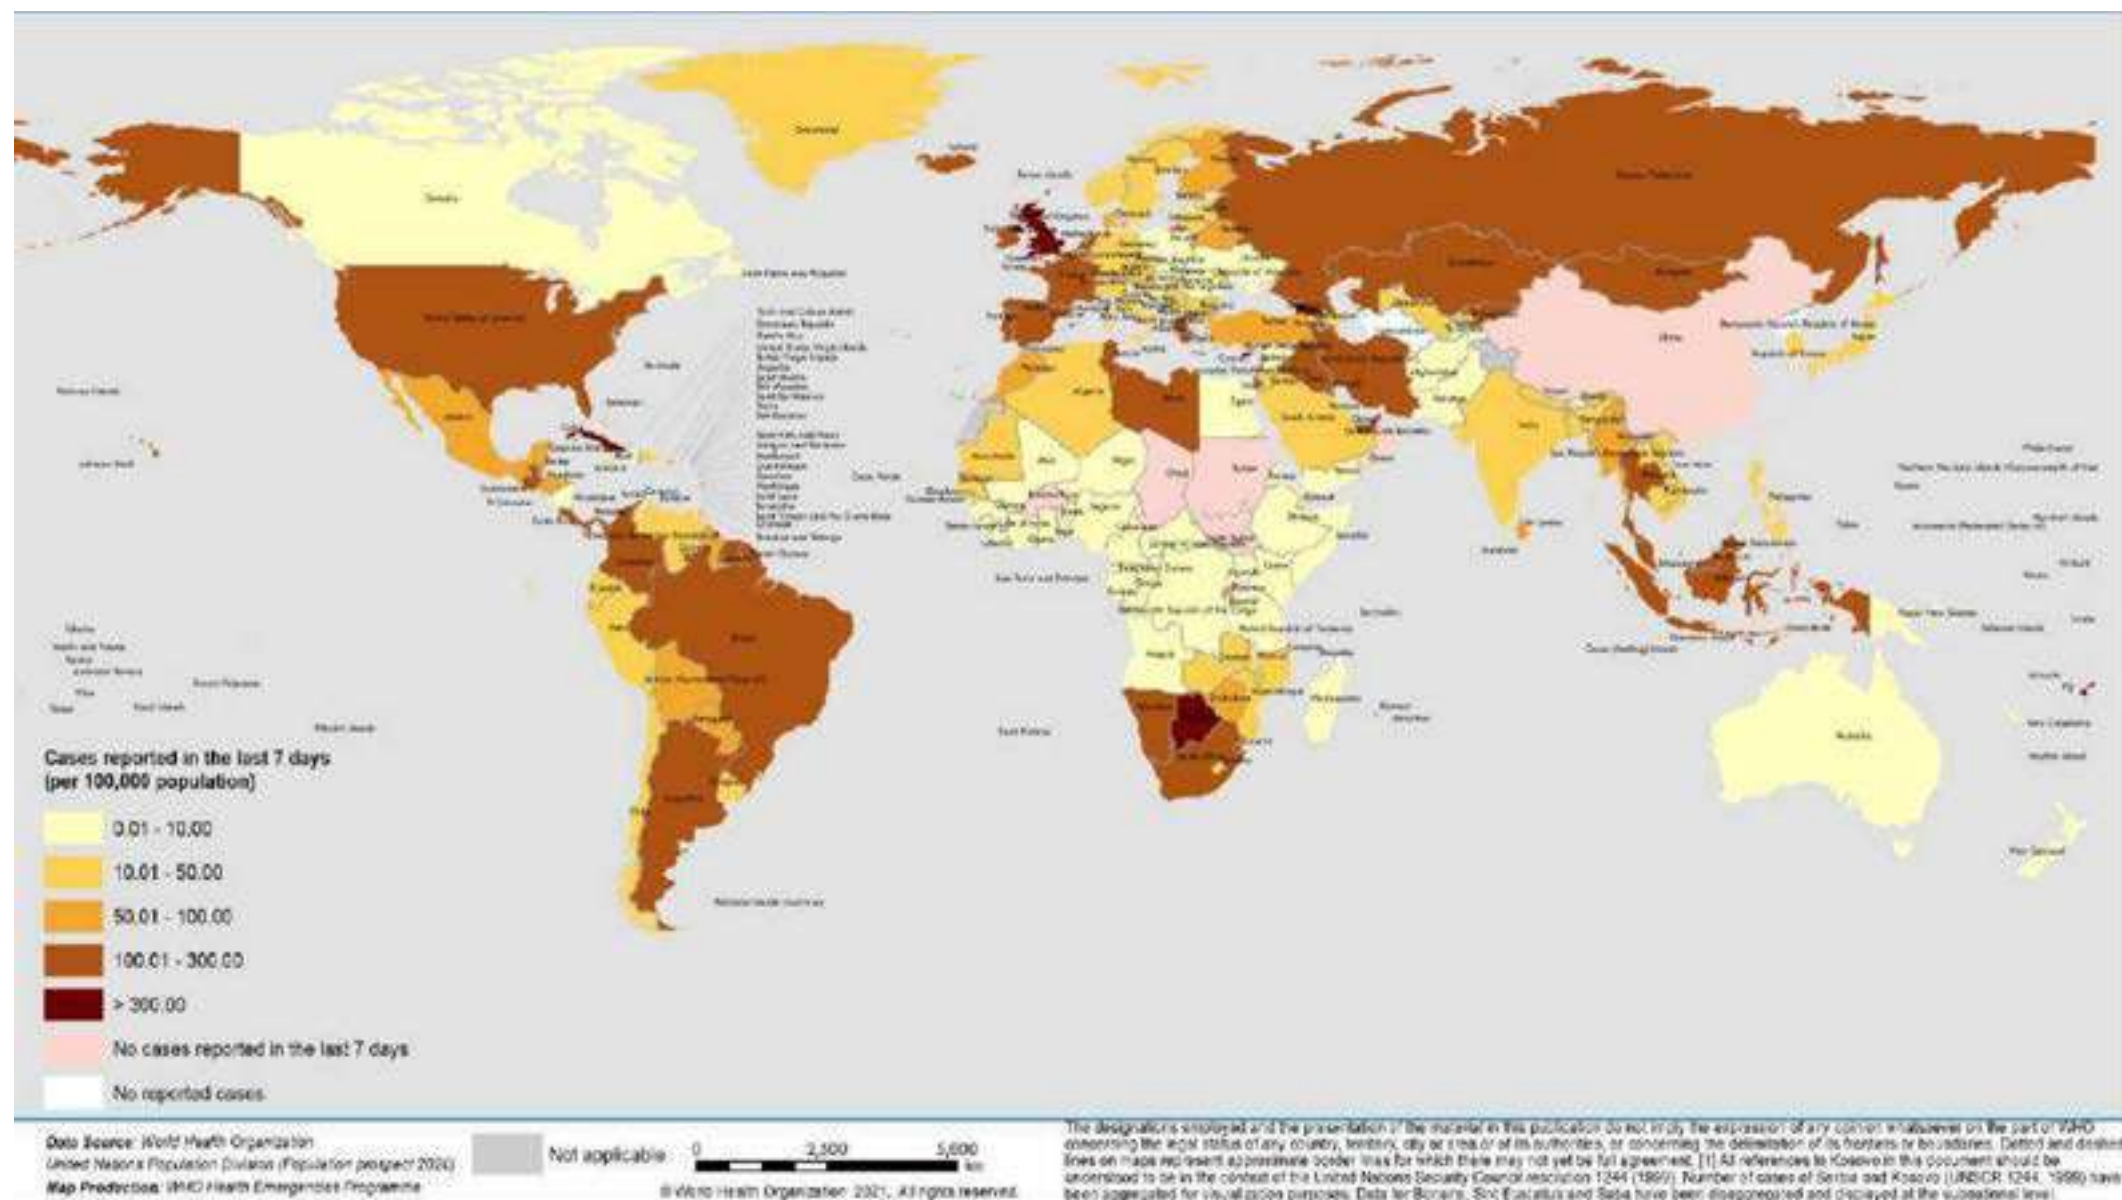

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

Special Focus: Evaluations of the effectiveness of COVID-19 vaccines in real-world settings

As of 20 July 2021, six vaccine types (AstraZeneca-Vaxzevria, Janssen Ad26.COV 2.5, Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty, COVID-19 vaccine BIBP, and Sinovac-CoronaVac) have received [WHO emergency use listing \(EUL\)](#) based, in part, on vaccine efficacy results from randomized controlled trials (RCTs). In contrast to vaccine efficacy, which is estimated in the controlled clinical trial setting, vaccine effectiveness, is estimated from observational (non-randomized) studies in real-world settings.

What is vaccine effectiveness?

Vaccine effectiveness (VE) is the percentage reduction in the risk or odds of disease or infection among vaccinated persons. It is important to note that breakthrough infections or disease (infection or symptomatic disease among individuals who have been fully vaccinated) are expected with all COVID-19 vaccines, even those with very high VE (such as greater than 90%), becoming more apparent as more of the population becomes vaccinated.

Evaluations of the effectiveness of multiple COVID-19 vaccines in different settings and populations are needed to assess how well these vaccines work in preventing symptomatic disease, severe disease, hospitalization, death, as well as infection and transmission, among other outcomes. Moreover, answers to some important public health questions can only be addressed by post-introduction VE studies, such as: whether additional doses would be needed to address declines in VE over time, or whether new vaccines or additional doses will be needed for SARS-CoV-2 variants of concern (VOCs). Vaccine effectiveness estimates may differ from the results of RCTs for valid reasons (e.g., different target populations, different vaccine schedule) or for invalid reasons (e.g., bias and confounding). However, biases and confounding can be minimized by careful planning, execution and analysis of VE studies.

How is vaccine effectiveness measured?

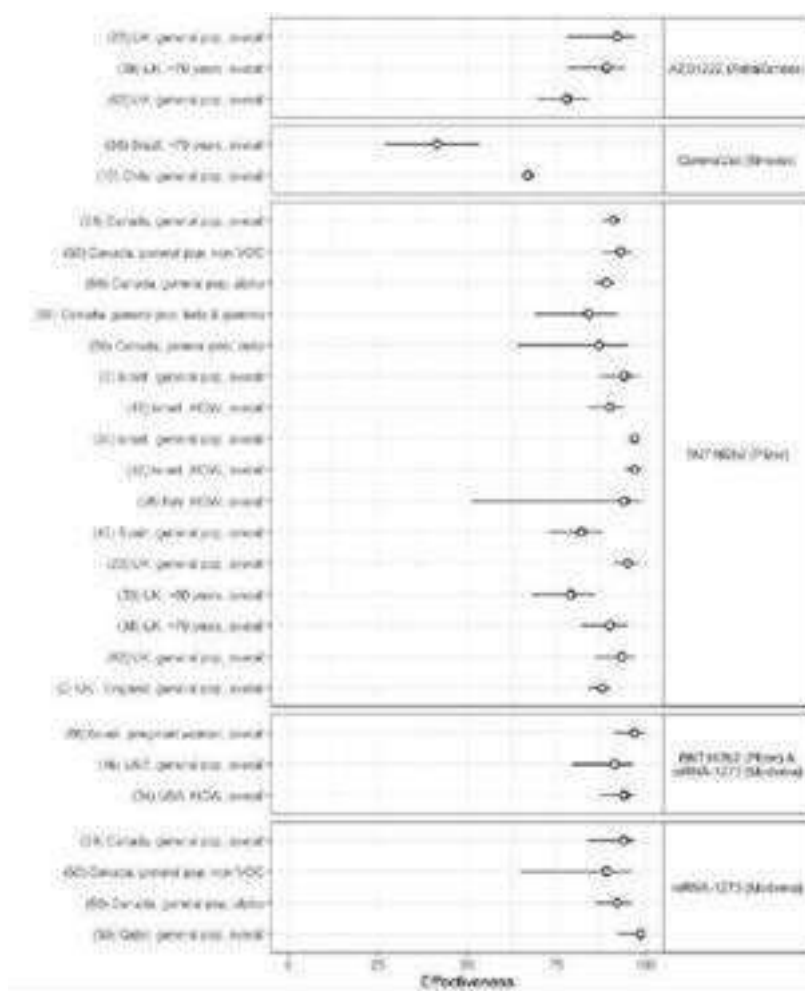

WHO has produced [best practice guidance](#) on how to undertake VE studies,¹ including for VOCs, and provides links to VE study protocols.² Two methodologies have been most widely used to evaluate COVID-19 VE to date¹: the retrospective cohort and the test-negative design case-control study. Some of the largest COVID-19 VE studies have used a retrospective cohort design and linkable electronic databases that compare rates of infection or symptomatic disease between vaccinated and unvaccinated individuals.^{3,4} Such large databases provide precise VE estimates and often allow adjustment for important confounders that can lead to bias, such as age, date of infection, geographic location and socioeconomic status.

The test-negative case-control design, where the vaccination status of persons testing positive for SARS-CoV-2 are compared to those who test negative, has also been widely deployed. The test-negative design is most often deployed among hospitalized patients or using an existing severe acute respiratory infection surveillance platform. This design minimizes confounding due to differences in healthcare-seeking behavior or access between vaccinated and unvaccinated persons, which can be present in traditional case-control studies.¹

What evidence is available to date?

As of 20 July 2021, there have been over 90 VE studies made publicly available in peer-reviewed or pre-print literature, though the quality of these studies varies considerably.⁵⁻⁷ The evidence base to date has been skewed, with 62% (58/93) of studies coming from three countries with early introduction of vaccination campaigns (i.e. Israel, the United Kingdom and the United States of America); and 71% (66/93) reporting on VE of only two vaccines - Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria. In general, symptomatic disease efficacy results from these studies, for fully vaccinated individuals, have been similar to the results of the RCTs that informed the WHO EUL decision (Figure 1). Overall, VE against severe disease, hospitalization and death has been higher than against non-severe symptomatic disease, with VE estimates for these more serious outcomes to be above 80% for AstraZeneca-Vaxzevria, Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty, and Sinovac-CoronaVac. (See [weekly summary table of Results of COVID-19 Vaccine Effectiveness Studies](#))

Figure 4. Vaccine effectiveness against COVID-19 symptomatic disease in fully vaccinated population

Note: Numbers in parentheses refer to references in the [weekly summary table](#). Horizontal lines indicate the 95% confidence interval.

Although the VE against infection and asymptomatic infection are slightly lower than against symptomatic disease for AstraZeneca- Vaxzevria, Moderna-mRNA-1273, and Pfizer BioNTech-Comirnaty,^{5,8-10} the VE estimates for these outcomes are almost uniformly $\geq 60\%$. Additionally, several studies have shown that the transmission to household members is reduced by approximately 50% when the infected household member was vaccinated with at least one dose as compared to unvaccinated.⁵ Importantly, VE appears to be consistently higher for all outcomes after full vaccination, defined as at least 7-14 days after the final dose.

Vaccine effectiveness and VOCs

There is widespread concern that existing COVID-19 vaccines may have reduced VE against the four VOCs designated by WHO (see [Tracking SARS-CoV-2 variants](#)). Neutralization studies (laboratory studies of how well vaccine-induced antibodies reduce the effect of virus) have shown that there is a several-fold reduction in neutralization against the VOCs, specifically Beta, Gamma and Delta (see [Weekly Epidemiological Update edition 49](#)). However, a reduction in neutralization does not directly correlate with reduced VE. This can be explained by several reasons: 1) there is currently no known threshold of neutralization (i.e., correlate of protection) below which vaccines no longer protect; 2) some vaccines produce higher neutralizing antibody concentrations so reductions in neutralization will likely have a lesser effect on the VE for these vaccines¹¹; 3) and other factors besides neutralizing antibody levels, such as cellular immunity, may maintain protection.

As an example, results of several studies evaluating VE of AstraZeneca-Vaxzevria and Pfizer BioNTech-Comirnaty against symptomatic disease and infection tend to be lower for the highly transmissible Delta variant as compared to the Alpha variant. However, this difference is reduced or not observed for severe disease outcomes, nor after receiving the second dose (Figure 2). More VE studies of additional vaccines against the Delta variant and other VOCs that look at multiple outcomes are needed to better characterize VE against VOCs (for more information on VOC impact on vaccines, see [Weekly Epidemiological Update edition 49](#)).

Conclusion

Although post-introduction VE studies are not a replacement for RCTs, they currently provide much of the rapidly emerging evidence for vaccine performance in real-world settings and can inform public health response and answer key public health questions that are not able to be answered by RCTs. WHO, along with its partners, will continue to track new evidence from published VE studies, as well as those that are ongoing and planned, to assure that they will contribute critical information for global, regional and national COVID-19 vaccine policy decisions.⁵

Figure 5. Comparison of Vaccine Effectiveness of Variants of Concern Alpha and Delta among fully vaccinated persons^{3,4,12,13}

Variant Alpha is shown as a blue circle and variant Delta is shown as an orange arrow.

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As these risks evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website). National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

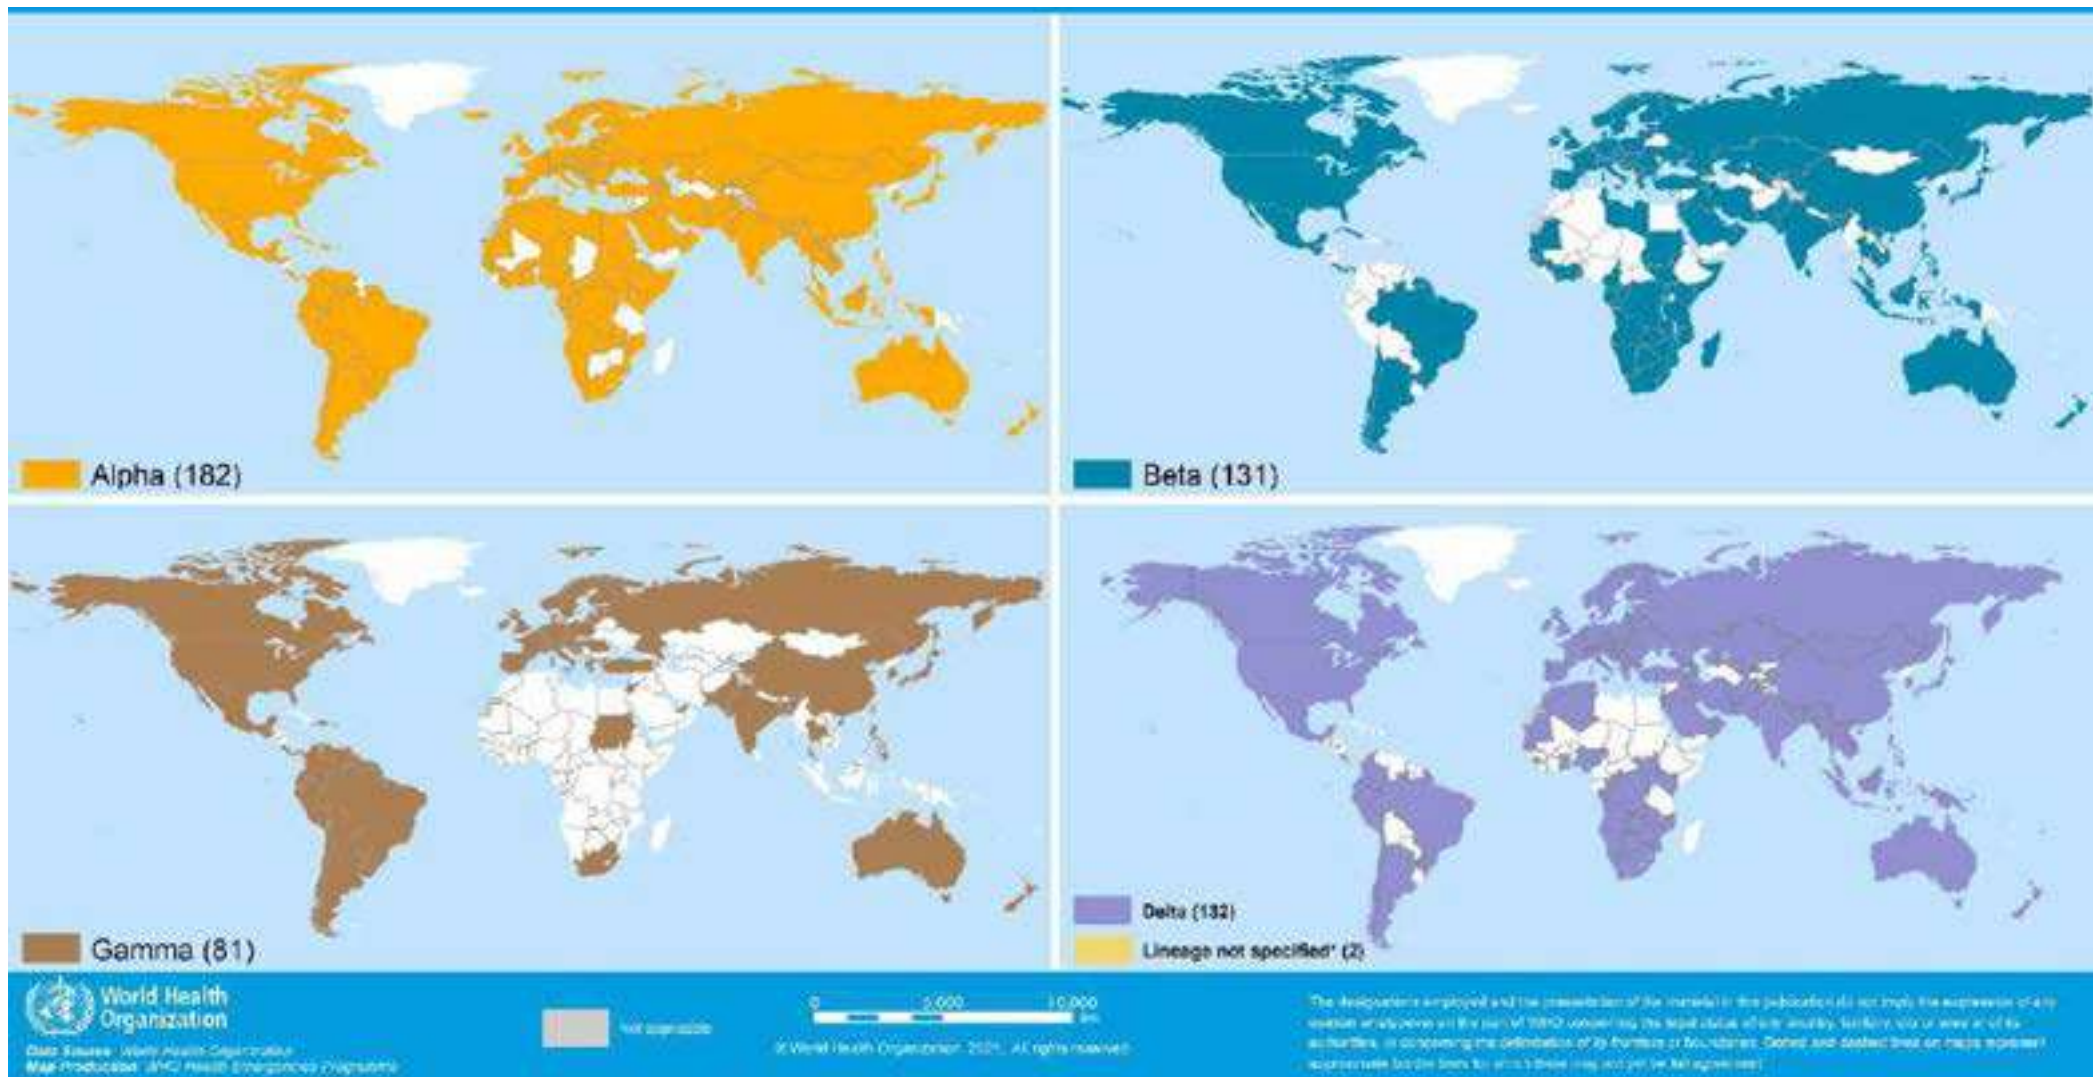

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 6, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on thorough risk assessments conducted systematically and routinely.

Figure 6. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 27 July 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews - Epidemiological week 19 – 25 July 2021

African Region

The African Region reported over 184 000 new cases, a 9% decrease, and over 4900 new deaths, similar numbers as compared to the previous week. Over the past two weeks, weekly cases in the Region have begun to decrease after increasing sharply over the previous three weeks. This is largely driven by declines observed in South Africa as many other countries in the Region are still reporting increasing case incidences. The highest numbers of new cases were reported from South Africa (84 225 new cases; 142.0 new cases per 100 000 population; -19%), Zimbabwe (14 664 new cases; 98.7 new cases per 100 000; -7%), and Botswana (11 524 new cases; 490.0 new cases per 100 000; +7%).

The highest numbers of new deaths were reported from South Africa (2812 new deaths; 4.7 new deaths per 100 000 population; +11%), Zimbabwe (462 new deaths; 3.1 new deaths per 100 000; similar to the previous week), and Namibia (254 new deaths; 10.0 new deaths per 100 000; -57%).

Updates from the [African Region](#)

Region of the Americas

After more than three months of overall declining trends in case and death incidence, in the past week the Region reported sharp increases in both. The Region of the Americas reported over 1.2 million new cases and just under 29 000 new deaths, a 30% and a 29% increase respectively as compared to the previous week. The highest numbers of new cases were reported from the United States of America (500 332 new cases; 151.2 new cases per 100 000; +131%), Brazil (324 334 new cases; 152.6 new cases per 100 000; +13%), and Colombia (104 399 new cases; 205.2 new cases per 100 000; -20%).

The highest numbers of new deaths were reported from Ecuador (8864 new deaths; 50.2 new deaths per 100 000; +7349%), Brazil (7942 new deaths; 3.7 new deaths per 100 000; -9%), and Colombia (2855 new deaths; 5.6 new deaths per 100 000; -21%).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The number of weekly cases reported in the Eastern Mediterranean Region declined in the past week after increasing sharply from mid-June through to mid-July. The Region recorded over 338 000 new cases in the past week, similar to the previous week. Deaths, however, continued to increase this week by 8% as compared to the previous week with over 4200 new deaths reported. The highest numbers of new cases were reported from the Islamic Republic of Iran (163 207 new cases; 194.3 new cases per 100 000; +2%), Iraq (60 487 new cases; 150.4 new cases per 100 000; -1%), and Tunisia (28 491 new cases; 241.1 new cases per 100 000; -43%).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1566 new deaths; 1.9 new deaths per 100 000; +23%), Tunisia (1194 new deaths; 10.1 new deaths per 100 000; +3%), and Iraq (443 new deaths; 1.1 new deaths per 100 000; +62%).

Updates from the [Eastern Mediterranean Region](#)

European Region

After reporting increases in weekly case and death incidence for the past month, the European Region this week reported numbers of cases and deaths similar to that of the past week (over 1.0 million cases and 7500 deaths reported). The highest numbers of new cases were reported from the United Kingdom (282 920 new cases; 416.8 new cases per 100 000; a 5% decrease), the Russian Federation (168 408 new cases; 115.4 new cases per 100 000; similar to the previous week), and France (117 832 new cases; 181.2 new cases per 100 000; a 178% increase).

The highest numbers of new deaths were reported from the Russian Federation (5455 new deaths; 3.7 new deaths per 100 000; a 1% increase), the United Kingdom (447 new deaths; 0.7 new deaths per 100 000; a 57% increase), and Turkey (391 new deaths; 0.5 new deaths per 100 000; a 32% increase).

Updates from the [European Region](#)

South-East Asia Region

After reporting an increase in weekly cases for three consecutive weeks, the Region reported a slight decrease (-7%) in cases this week, with over 775 000 new cases reported. However, new weekly deaths have continued to increase for the past three weeks, with over 21 000 new deaths reported in the past week, a 30% increase as compared to the previous week. The highest numbers of new cases were reported from Indonesia (289 029 new cases; 105.7 new cases per 100 000; a 17% decrease), India (265 836 new cases; 19.3 new cases per 100 000; similar to the previous week), and Thailand (93 916 new cases; 134.6 new cases per 100 000; a 40% increase).

The highest numbers of new deaths were reported from Indonesia (9697 new deaths; 3.5 new deaths per 100 000; a 36% increase), India (6942 new deaths; 0.5 new deaths per 100 000; a 25% increase), and Myanmar (2111 new deaths; 3.9 new deaths per 100 000; an 82% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

In the Western Pacific Region, cases have continued to increase for a month, with over 238 000 new cases reported in the past week, a 25% increase compared to the previous week. Deaths have also shown an increasing trend for the past several weeks, with over 2100 new deaths reported in the past week, this remains similar to the previous week's trend. The highest numbers of new cases were reported from Malaysia (90 542 new cases; 279.7 new cases per 100 000; a 15% increase), Viet Nam (43 911 new cases; 45.1 new cases per 100 000; a 95% increase), and the Philippines (40 932 new cases; 37.4 new cases per 100 000; a 16% increase).

The highest numbers of new deaths were reported from Malaysia (1036 new deaths; 3.2 new deaths per 100 000; a 30% increase), the Philippines (533 new deaths; 0.5 new deaths per 100 000; a 32% decrease), and Cambodia (178 new deaths; 1.1 new deaths per 100 000; a 9% decrease).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the WTO - WHO High Level Dialogue: Expanding COVID-19 Vaccine Manufacture to Promote Equitable Access - 21 July](#), the Director-General highlighted:
 - Over 3.5 billion vaccines have been distributed globally, but more than 75% of those have gone to just ten countries. To reach at least 40% of the global population by the end of the year, and 70% by the middle of 2022, we need 11 billion doses of vaccine, and dose sharing is vital to fill our current supply gap.
 - In July, WHO and our COVAX partners announced the first COVID-19 mRNA vaccine technology transfer hub, to be set up in South Africa. Additionally, WHO has prequalified numerous health technologies including vaccines from manufacturers in middle-income countries. These manufacturers have shown that they can produce according to international standards of quality, safety and efficacy.
 - WHO continues to provide technical assistance to companies to build capacity, especially in Africa, Asia, and Latin America, through the COVID-19 Technology Access Pool.
- In his [speech at the 138th International Olympic Committee Session](#), the Director-General emphasized:
 - A massive global push to vaccinate against COVID-19 is needed - at least 10% of the population of every country by September 2021, at least 40% by the end of the year, and 70% by the middle of 2022.
 - WHO's top priority is universal health coverage, so that all people can access the health services they need, where and when they need them, without facing financial hardship.

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>.

As of 27 July, the [WHO Coronavirus \(COVID-19\) Dashboard](#) will be updated once per day and the daily case and death counts for all WHO regions will be published by 23:59 CET/CEST on weekdays. Data reported over the weekend will be published on the following Monday as soon as they become available.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

WHO from official sources.

ation become available.

** Beta was excluded for Uruguay this week based on further information.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 49, published 20 July 2021

In this edition:

- [Global overview](#)
- [Special focus: Release of a detailed WHO COVID-19 global surveillance dashboard](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 18 July 2021

The global number of new cases reported last week (12-18 July 2021) was over 3.4 million, a 12% increase as compared to the previous week (Figure 1). Globally, COVID-19 weekly case incidence increased with an average of around 490 000 cases reported each day over the past week as compared to 400 000 cases reported daily in the previous week. Following a steady decline for over two months, the number of weekly deaths reported was similar to the previous week, with almost 57 000 deaths reported. The cumulative number of cases reported globally is now over 190 million and the number of deaths exceeds 4 million. At this rate, it is expected that the cumulative number of cases reported globally could exceed 200 million in the next three weeks. Last week, four Regions (all except the Regions of the Americas and Africa) reported an increase in case incidence. The Western Pacific Region recorded the largest increase in case incidence as compared to the previous week, followed by the European Region (30% and 21%, respectively) (Table 1). The South-East Asia and Eastern Mediterranean Regions also recorded increases in case incidence, 16% and 15%, respectively, as compared to the previous week. The number of deaths increased in the South-East Asia and the Western Pacific Regions by 12% and 10%, respectively, as compared to the previous week. The African, Eastern Mediterranean and European Regions reported similar numbers of deaths as compared to the previous week, whereas the Region of Americas reported a 6% decrease.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 18 July 2021**

**See Annex 2: Data, table and figure notes

The Region of the Americas and the European Region reported the highest weekly case incidence per capita, both reporting 95 new cases per 100 000 population, as well as the highest number of deaths per population over the past week, with 2.2 and 0.8 new deaths per 100 000 population, respectively. The Eastern Mediterranean and South-East Asia Regions reported 48 and 41 new cases per 100 000 population, respectively.

Despite efforts to extend vaccination coverage, many countries across all six WHO Regions continue to experience surges in COVID-19 cases. Over the past week, the highest numbers of new cases were reported from Indonesia (350 273 new cases; 44% increase), the United Kingdom (296 447 new cases; 41% increase), Brazil (287 610 new cases; 14% decrease), India (268 843 new cases; 8% decrease), and the United States of America (216 433 new cases; 68% increase).

Globally, cases of the Alpha variant have been reported in 180 countries, territories or areas (hereafter countries; six new countries in the past week), while 130 countries (seven new countries) have reported cases of the Beta variant; 78 countries (three new countries) have reported cases of the Gamma variant; and 124 countries (13 new countries) have reported cases of the Delta variant.

The increases in transmission appear to be driven by four factors: the circulation of more transmissible Variants of Concern (VOCs), relaxation of public health social measures originally intended to control transmission, increases in social mixing, and the large number of people who remain susceptible to SARS-CoV-2 infection as a result of inequitable vaccine distribution around the world.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 18 July 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	967 205 (28%)	0%	74 734 644 (39%)	22 411 (39%)	-6%	1 960 619 (48%)

**See Annex 2: Data, table and figure notes

Over eighteen months into the COVID-19 pandemic, the need for global epidemiological surveillance for COVID-19 continues to be of high importance. The evolution of transmission patterns as the pandemic continues will likely be influenced by the impact of the COVID-19 vaccination campaigns and by the emergence of more transmissible variants, or variants with properties of immune escape. Timely and complete surveillance data are therefore key to monitoring these changes.

The data reported by Member States are now publicly available through the [WHO COVID-19 detailed surveillance data dashboard](#), without editing or filtering by WHO. This dashboard complements the existing [WHO COVID-19 dashboard](#) and provides data by WHO Region and by country, stratified by age and sex, trends over time, case fatality ratios by age, testing, hospitalization, and data on health care workers. The WHO COVID-19 detailed surveillance data dashboard, and the downloadable dataset, provides the ability for users to conduct further analyses by country and over selected time periods.

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants.

For updates on VOCs and VOIs, and a list of Alerts for Further Monitoring, are available on the [WHO Tracking SARS-CoV-2 Variants website](#).

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at national and subnational levels, including through the expansion of genomic sequencing capacities, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 5, Annex 1). This distribution should nonetheless be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs is summarized in Table 2, as well as in [previous editions](#) of these COVID-19 Weekly Epidemiological Updates. Since the last detailed [update](#) on 6 July, new evidence has been published on the phenotypic characteristics of the Delta variant.

As of 20 July 2021, a total of 2 418 133 SARS-CoV-2 sequences have been submitted to [GISAID](#), a global science initiative and primary source that provides open access to genomic data. Over 220 000 (9%) of SARS-CoV-2 sequences submitted to GISAID are confirmed as the Delta Variant. As mentioned in our last update, based on the estimated transmission advantage of the Delta variant, it is expected that it will rapidly outcompete other variants and become the dominant circulating lineage over the coming months.¹ According to GISAID data, as of 20 July, the prevalence of Delta among the specimens sequenced over the past 4 weeks exceeded 75% in many countries worldwide including Australia, Bangladesh, Botswana, China, Denmark, India, Indonesia, Israel, Portugal, Russian Federation, Singapore, South Africa and the United Kingdom.

Growing evidence supports the increased transmissibility of the Delta variant as compared to non-VOCs. However, the exact mechanism for the increase in transmissibility remains unclear. A recent study from China during an outbreak of the Delta variant examined the time interval from the exposure of a quarantined population to the first positive PCR result and found that the interval may be shorter for the Delta variant when compared to non-VOCs [4 (IQR 3.00-5.00) days compared to 6 (IQR 5.00 to 8.00) days, respectively]. Moreover, the viral load of the first positive test of Delta infection was over 1200 times higher than non-VOCs, suggesting that this VOC may be able to replicate faster and be more infectious during the early stages of infection.²

A study from Canada analysing data from over 200 000 COVID-19 cases showed an increase in virulence of the Delta variant when compared to non-VOCs. Among the COVID-19 cases, the risk of hospitalization, ICU admission and death associated with the Delta variant compared to non-VOCs increased by 120% (93-153%), 287% (198-399%) and 137% (50-230%), respectively. Increased disease severity was also identified for Alpha, Beta and Gamma variants combined when compared to non-VOCs: 59% (49-69%) for hospitalization, 105% (82-134%) for ICU admission and 61% (40-87%) for death.³

Preliminary findings from a study in the United Kingdom, which measured antibodies in a cohort of 112 SARS-CoV-2-infected individuals, indicated significantly reduced neutralization titres (2.5 to 5-fold reduction) in sera from individuals infected with Delta, Beta or Alpha variants with a S:484K mutation (but not Alpha without any additional mutations) when compared to the non-VOCs.⁴

A recent modelling study simulated the effects of non-pharmaceutical interventions (NPIs) in the context of expanding vaccination coverage and the predominance of the Delta variant in Germany, while accounting for age-associated factors and commuting activities. The authors indicated that timely implementation of NPIs in combination with masks and testing would considerably reduce the chance of a further surge in infections.⁵

Table 2: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility and secondary attack rate ⁶	Increased transmissibility ⁷	Increased transmissibility ⁸	Increased transmissibility and secondary attack rate ^{1,9,10}
Disease severity	Increased risk of hospitalization ¹¹ , possible increased risk of severity and mortality ¹²	Not confirmed, possible increased risk of in-hospital mortality ^{13,14}	Not confirmed, possible increased risk of hospitalization ¹⁵	Increased risk of hospitalization ^{3,16}
Risk of reinfection	Neutralizing activity retained, ¹⁷ risk of reinfection remains similar ^{18,19}	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ^{20–23}	Moderate reduction in neutralizing activity reported ^{24,25}	Reduction in neutralizing activity reported ²⁶
Impacts on diagnostics	Limited impact – S gene target failure (SGTF); no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed ²⁷	No impact on RT-PCR or Ag RDTs observed ¹⁶	None reported to date	None reported to date

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

VOC impacts on vaccines

Table 3 presents the impact of variants on vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE due to variants compared to VE in non-VOC settings. Of note, reductions in VE do not necessarily mean loss of protection, as indicated by the absolute VE estimate. For example, a 10-percentage point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean good protection, as is the case for AstraZeneca-Vaxzevria.

Since the [6 July update](#), two notable studies have provided further evidence of the performance of mRNA vaccines against Alpha and Beta variants. The first, a test-negative case-control study in the United States of America, found that vaccination with two doses of Moderna-mRNA-1273 or Pfizer BioNTech-Comirnaty vaccines was 92.8% (95% CI: 83.0-96.9%) effective at preventing hospitalization due to the Alpha variant 14 or more days after receipt of the second dose; VE against all variants was 86.9% (95% CI: 80.4-91.2%). It should be noted that approximately 21% of the 1210 adults participating in the study were immunosuppressed.²⁸

A second study, from Qatar, evaluated VE of Moderna-mRNA-1273 against SARS-CoV-2 infection and severe disease due to Alpha and Beta variants among a large cohort of adults using a matched test negative case-control design. Adjusted VE against infection due to the Alpha and Beta variants 14 or more days after receipt of the second dose was 100% and 96% (95% CI: 90.9-98.2%), respectively. Single dose VE against infection due to Alpha and Beta was reduced: 88.2% (95% CI: 83.8-91.4%) and 68.2% (95% CI: 64.3-71.7%), respectively. The study also evaluated VE of Moderna-mRNA-1273 against asymptomatic, symptomatic, and severe, critical, or fatal disease due to all variants (predominantly Alpha and Beta). VE of two doses of the vaccine ranged from 90-99% for these outcomes. VE of a single dose remained high for severe, critical or fatal disease (84%) but was markedly lower for asymptomatic and symptomatic disease at 47.3% (95% CI: 37.6-55.5%) and 66.0% (60.6-70.7%), respectively, thus, highlighting the importance of two doses.²⁹

Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used.

The number of studies is shown in parentheses.

“Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

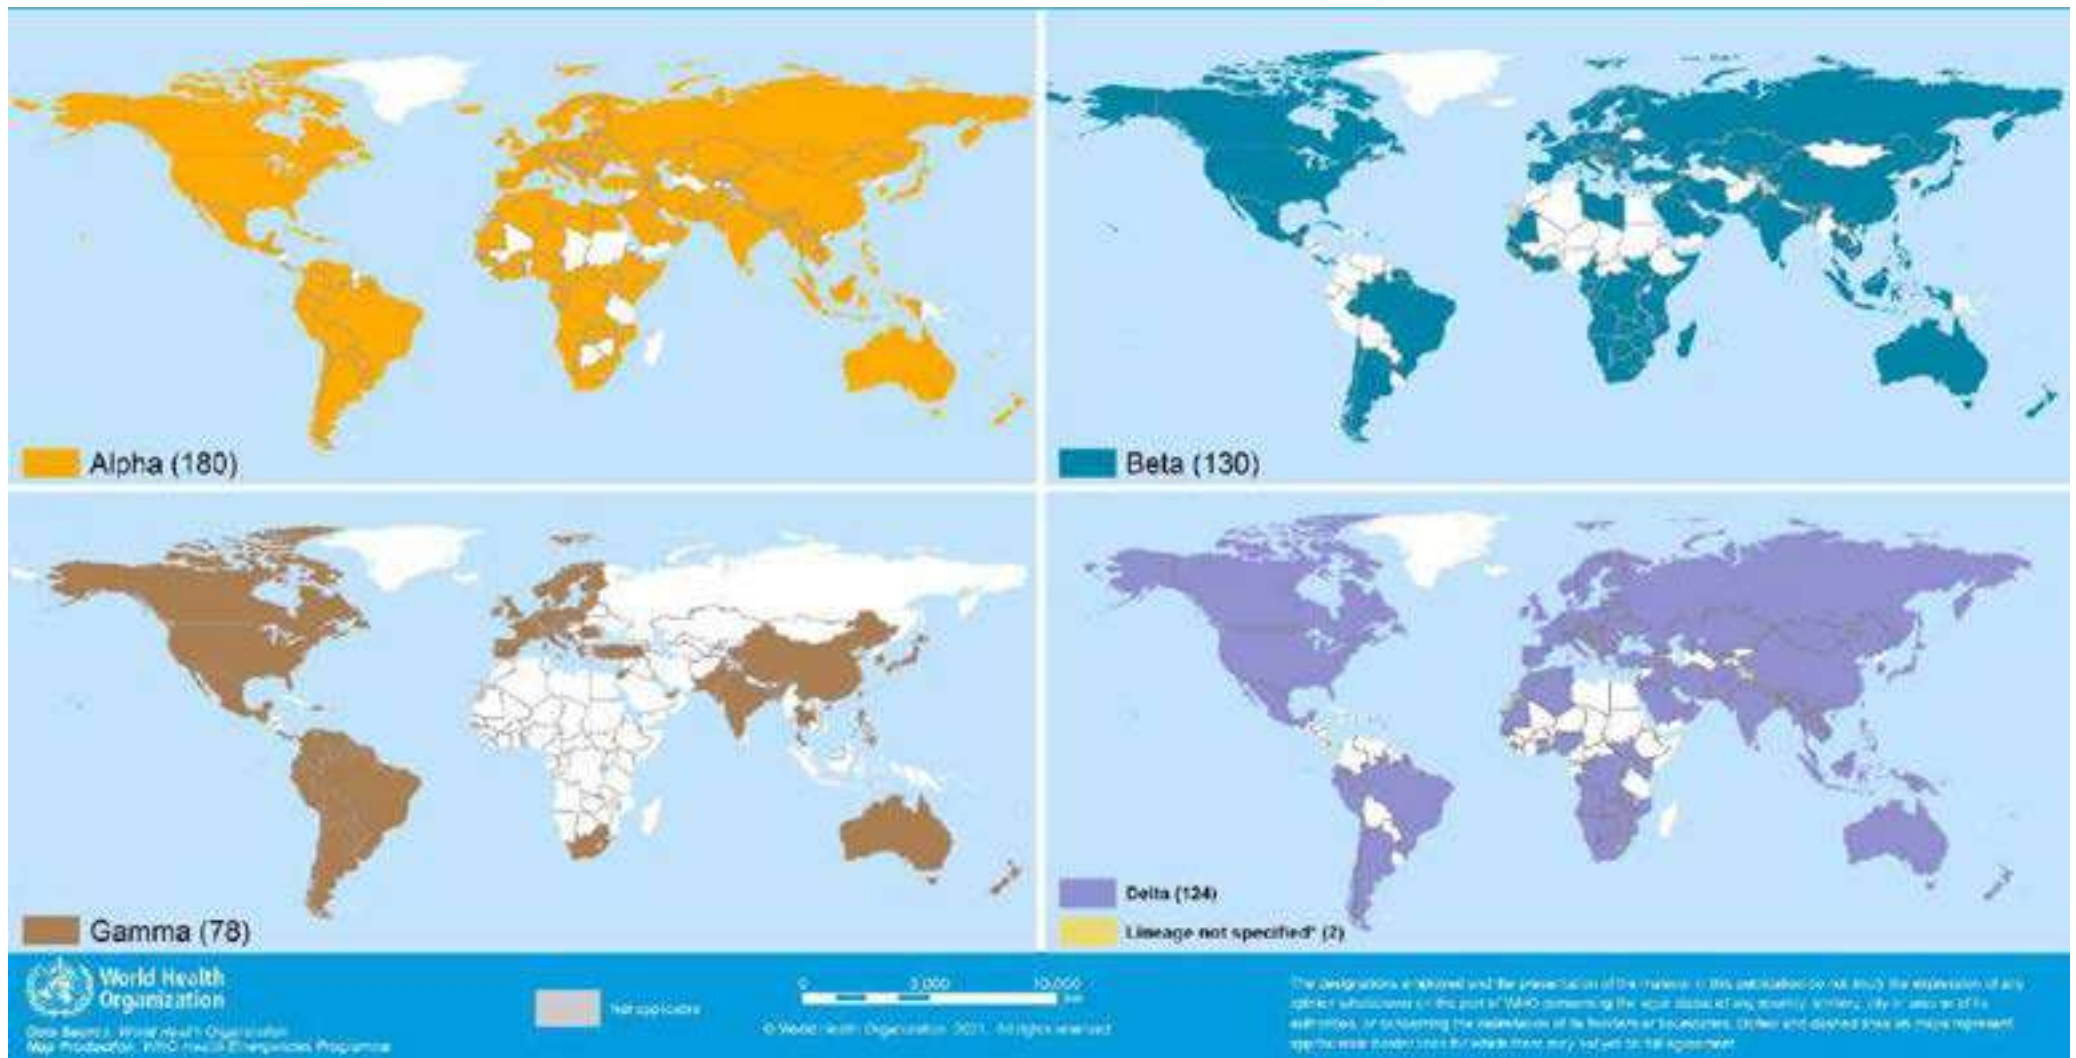

Additional notes on VOC impacts on vaccines

- Studies presenting VOC specific VE estimates for full vaccination (≥ 7 days post final dose) are assessed against a comparator VE estimate to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for severe disease (phase 3 RCT efficacy estimates against severe disease are used as comparator since within study comparator is unavailable) and for infection (when phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection even without a comparator if very high VE estimate against a VOC is reported (i.e., $>90\%$).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates between different studies. In addition, the reductions presented consider VE point estimates only and do not take into account the uncertainty around these estimates. The reductions in VE noted should be interpreted with these limitations in mind.

Figure 5. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 20 July 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews - Epidemiological week 12 – 18 July 2021

African Region

Following an increasing trend in the weekly number of new COVID-19 cases and deaths since early May 2021, the Region reported a slight decrease in case incidence (with over 202 000 new cases) and mortality (over 4800 new deaths) in the past week, as compared to the previous week. These trends were largely driven by decreases reported in South Africa, which reported the highest numbers of new cases (104 583 cases) and more than 50% of the cases reported in the region in the past week. Other countries reporting high numbers of new cases include: Zimbabwe (15 760 cases; 106.0 cases/100 000; +20%), and Botswana (10 745 cases; 456.9 cases/100 000; +172%), while the highest numbers of new cases per population were reported in Seychelles (545 cases/100 000; -28%), Botswana (see above) and Namibia (317 cases/100 000; -19%).

The highest numbers of new deaths were reported from South Africa (2538 deaths; 4.3 deaths/100 000; -4%), Namibia (595 deaths; 23.4/100 000; -109%), and Zimbabwe (462 deaths; 3.1 deaths/100 000; +73%).

Updates from the [African Region](#)

Region of the Americas

The Region reported over 967 000 new cases, a similar number as compared to the previous week, and over 22 000 new deaths, a 6% decrease as compared to the previous week. A decline in weekly case incidence has been reported since the last peak in mid-April 2021, however, very high transmission levels and high mortality rates are still observed across many countries in the Region. The highest numbers of new cases were reported from Brazil (287 610 cases; 135.3 cases/100 000; -14%), the United States of America (216 433 cases; 65.4 cases/100 000; +68%), and Colombia (129 713 cases; 254.9 cases/100 000; -26%), while the highest numbers of new cases per population were reported in the British Virgin Islands (2900 cases/100 000; +16%), Martinique (574.8 cases/100 000; +425%) and Cuba (388.8 cases/100 000; +43%).

The highest numbers of new deaths were reported from Brazil (8710 deaths; 4.1 deaths/100 000; -11%), Colombia (3602 deaths; 7.1/100 000; -10%), and Argentina (2927 deaths; 6.5 deaths/100 000; similar to the previous week).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Region has reported a marked increase in weekly case incidence for more than one month with over 354 000 new cases reported, a 15% increase as compared to the previous week. This increase has been driven mainly by surges in several countries in the Region including Iran, Iraq, Libya, Pakistan and Morocco. The Region reported over 3800 new deaths, a similar number as compared to the previous week.

The highest numbers of new cases were reported from the Islamic Republic of Iran (145 293 cases; 173.0 cases/100 000; +27%), Iraq (61 268 cases; 152.3 cases/100 000; + 8%), and Tunisia (49 777 cases; 421.2 cases/100 000; similar to the previous week), while the highest weekly case incidence per population was registered in Tunisia (see above), Kuwait (245.1 cases/100 000) and Libya (235.7 cases/100 000). The highest numbers of new deaths were reported from the Islamic Republic of Iran (1272 deaths; 1.5 deaths/100 000; +9%), Tunisia (1110 deaths; 9.4 deaths/100 000; +13%), and Afghanistan (423 deaths; 1.1 deaths/100 000; -19%).

Updates from the [Eastern Mediterranean Region](#)

European Region

In the European Region, weekly case incidence has increased significantly across the past month, with over 885 000 new cases reported in the past week, a 21% increase as compared to the previous week. Over 7100 new deaths were reported in the past week, similar to the number reported during the previous week. The increase in reported COVID-19 cases in the Region since mid-June 2021 has been observed across all age groups, but has been most pronounced in those aged 15-24 years. The highest numbers of new cases were reported from the United Kingdom (296 447 cases; 436.7 cases/100 000; +41%), the Russian Federation (174 800 cases; 119.8 cases/100 000; similar to the previous week), and Spain (85 802 cases; 181.3 cases/100 000; -29%), while the highest weekly case incidence per population was registered in Jersey (1274 cases/100 000), Cyprus (779 cases/100 000) and Gibraltar (451 cases/100 000).

The highest numbers of new deaths were reported from the Russian Federation (5417 deaths; 3.7 deaths/100 000; +7%), Turkey (296 deaths; 0.4 deaths/100 000; -7%), and the United Kingdom (284 deaths; 0.4 deaths/100 000; +48%).

Updates from the [European Region](#)

South-East Asia Region

The Region reported over 829 000 new cases and over 16 000 new deaths, increases of 16% and 12%, respectively as compared to the previous week. Weekly case incidence and mortality in India and Sri Lanka continue to decline, with the regional trends being driven mainly by marked increases in Indonesia, Thailand and Myanmar. The highest numbers of new cases were reported from Indonesia (350 273 cases; 128.1 cases/100 000; +44%), India (268 843 cases; 19.5 cases/100 000; -8%) and Bangladesh (82 800 cases; 50.3 cases/100 000; +9%), while the highest weekly case incidence per population was registered in Maldives (150 cases/100 000), Indonesia (see above) and Thailand (96 cases/100 000).

The highest numbers of new deaths were reported from Indonesia (7118 deaths; 2.6 deaths/ 100 000; +21%), India (5569 deaths; 0.4 deaths/100 000; -8%), and Bangladesh (1475 deaths; 0.9 deaths/100 000; +9%).

Updates from the [South-East Asia Region](#)

Western Pacific Region

Over the past week, weekly case incidence increased sharply in the Region with over 191 000 new cases reported, representing a 30% increase as compared to the previous week. This trend was driven mainly by increases in Fiji, Japan, Malaysia and Viet Nam. The Region reported over 2000 new deaths this week, a 10% increase as compared to the previous week. The highest numbers of new cases were reported from Malaysia (78 660 cases; 243.0 cases/100 000; +44%), the Philippines (35 235 cases; 32.2 cases/100 000; similar to the previous week), and Viet Nam (22 532 cases; 23.1 cases per 100 000; +146%), while the highest weekly case incidence per population was registered in Fiji (719 cases/100 000), Mongolia (297 cases/100 000) and Malaysia (see above).

The highest numbers of new deaths were reported from Malaysia (799 deaths; 2.5 deaths/100 000; +26%), the Philippines (782 deaths; 0.7 deaths/100 000; similar to the previous week), and Cambodia (195 deaths; 1.2 deaths/100 000; +5%).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the Member State Information Session on Origins – 16 July 2021](#), the Director-General highlighted the proposed next steps that the WHO Secretariat will take to advance the studies to identify the origins of SARS-CoV-2. He emphasized that finding where the virus came from is essential, not only for understanding how the pandemic started and preventing future outbreaks, but also as an obligation to the families of the 4 million people who have lost someone they love, and the millions who have suffered.
- In his [opening remarks at the 8th meeting of the IHR Emergency Committee on COVID-19 – 14 July 2021](#), the Director-General called for a massive push to vaccinate at least 10% of the population of every country by September 2021, at least 40% by the end of this year, and at least 70% by the middle of 2022. To reach these targets, he highlighted the need for 11 billion vaccine doses. He expressed his gratitude for the announcements made by the G7 countries that together will donate 870 million doses, primarily through COVAX, but emphasized that much more is needed, much faster.

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>

As of 20 July, WHO will stop collecting reports of national-level transmission classifications and displaying transmission classifications on the [global COVID-19 dashboard](#). WHO however encourages Member States to continue the self-monitoring of transmission at the sub-national level to inform adjustments to PHSM.

Annex 1. List of countries/territories/areas reporting Variants of Concern as of 20 July 2021**

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

from official sources.

ation become available.

** Alpha was excluded for Benin, Botswana, Eswatini and Madagascar, and unspecified B.1.617 was excluded for Estonia this week based on further information.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 48, published 13 July 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on WHO COVID-19 global rapid risk assessment](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 11 July 2021

The global number of new cases reported last week (5-11 July 2021) was nearly 3 million, a 10% increase as compared to the previous week (Figure 1). Following a steady decline for nine consecutive weeks, the number of weekly deaths increased by 3% this week compared to the previous week, with over 55,000 deaths reported. Globally, COVID-19 incidence increased with an average of over 400,000 cases reported each day as compared to 370,000 from the previous week. The cumulative number of cases reported globally is now over 186 million and the number of deaths exceeds 4 million.

This week, all Regions with the exception of the Americas recorded an increase in incidence. The Eastern Mediterranean Region recorded the largest increase in incidence (25%) followed by European Region with a 20% increase as compared to the previous week (Table 1). The African Region had the smallest percentage increase in incidence with a 5% increase. However, the region recorded a 50% increase in the number of deaths as compared to the previous week. The South-East Asia Region also recorded a significant increase in number of deaths, reporting a 26% increase as compared to the previous week. The Region of the Americas reported a 3% decline in incidence and an 11% decrease in number of deaths reported last week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 11 July 2021**

**See [Annex 2: Data, table and figure notes](#)

The highest numbers of new cases were reported from Brazil (333 030 new cases; 9% decrease), India (291 789 new cases; 7% decrease), Indonesia (243 119 new cases; 44% increase), The United Kingdom (210 277 new cases; 30% increase), and Colombia (174 320 new cases; 15% decrease). Over the past week, the highest numbers of new cases per 100 000 population were reported from British Virgin Islands (2497 new cases per 100 000 pop), Seychelles (763 new cases per 100 000 pop), Cyprus (673 new cases per 100 000 pop), Jersey (628 new cases per 100 000 pop), and Fiji (490 new cases per 100 000 pop).

Globally, cases of the Alpha variant have been reported in 178 countries, territories or areas (six new countries in the past week), while 123 countries (three new countries) reported cases of the Beta variant; 75 countries (three new countries) reported cases of the Gamma variant; 111 countries (15 new countries) reported cases of the Delta variant.

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 11 July 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	962 280 (32%)	-3%	73 767 194 (40%)	23 715 (42%)	-11%	1 938 190 (48%)
Europe	653 803 (22%)	20%	56 935 257 (31%)	6 926 (12%)	-1%	1 196 301 (30%)
South-East Asia	712 210 (24%)	16%	35 931 354 (19%)	14 600 (26%)	26%	510 539 (13%)

Special Focus: Update on WHO COVID-19 global rapid risk assessment

The COVID-19 pandemic continues to evolve, as does our understanding of the SARS-CoV-2 virus, and the response needed to control the spread and impact of the virus. In WHO's most recent rapid risk assessment, conducted on 9 July 2021, the global public health risk remains very high.

Under the [Emergency Response Framework](#), WHO undertakes risk assessments and situation analyses on a regular basis to inform our response to emerging situations. In addition, WHO periodically reviews the current risk status of public health events through an in-depth hazard, exposure and context assessment. This also includes a review of the vulnerabilities and capacities available to respond to the public health event and to investigate the current risk to human health, risks of ongoing spread globally, and risk of insufficient control capacities. Such assessments are used as an internal WHO decision-making tool; they are also used to support independent deliberations, including (but not limited to) meetings of the International Health Regulations (IHR 2005) Emergency Committee. To date, a total of 11 global rapid risk assessments have been undertaken for COVID-19, and additional assessments have been conducted for specific events surrounding the emergence of SARS-CoV-2 Variants of Concern (VOCs). Here, we provide a synopsis of the most recent in-depth global rapid risk assessment for COVID-19.

The global public health risks associated with COVID-19 remain very high. Following a two-month steady decline at the global level, case incidence rates remain high (once again approaching around 3 million new confirmed cases per week) and are increasing in most regions and in many countries. Following a decline in the death rate since the peak registered at the end of April 2021, a slight increase in deaths has been reported this week in comparison to the previous week, with several countries across all WHO regions with low levels of vaccination now reporting sharp increases in cases, hospitalizations, and deaths.

As the SARS-CoV-2 virus continues to circulate and evolve, emerging variants of interest and concern are being characterised by WHO and partners, to evaluate increased transmissibility and other potential phenotypic impacts. The four VOCs characterized to date (Alpha; Beta; Gamma, Delta) have demonstrated increased transmissibility. The Delta variant has now been detected in at least 111 countries across all six WHO regions in the last two months and has shown higher transmissibility than other VOCs identified to date. The increased transmissibility means that it is likely to become the dominant variant globally over the coming months. The emergence of more transmissible variants, coupled with the relaxation and inappropriate use of public health and social measures (PHSM) and increased social mobility and mixing, and low vaccination coverage in many countries, continue to contribute to rapid surges in incidence, hospitalizations and deaths in many countries. Moreover, in large parts of the world, there remain gaps in epidemiological surveillance, testing, and genomic sequencing, and this limits our ability to monitor and assess the impact of current and future variants in a timely manner.

While almost a quarter (24.7%) of the world's population has received at least one dose of a COVID-19 vaccine (over three billion doses administered), there are vast inequities in vaccine distribution and administration with the majority of vaccines administered in a small number of high and upper-middle-income countries. The COVAX facility has been working to reduce this gap, but a large proportion of the world's population remains susceptible to SARS-CoV-2 infection. The breadth and quality of evidence of the efficacy and effectiveness of current vaccines against emerging variants remains limited; nevertheless, the available evidence suggests full vaccination offers high levels of protection against severe disease and death for all four VOCs, with mixed evidence as to the impacts on infection, mild-moderate disease, and transmission. Virus evolution and the phenotypic impacts of all variants, including potential immune escape, require close monitoring and assessment, including the possible need for future adjustments to vaccine composition, vaccination strategies and/or coverage targets.

In response to the COVID-19 pandemic, countries have moved in and out of restrictions of varying stringency over the past 18 months with many now facing considerable pressure to lift all remaining PHSM. Social mixing and mobility are increasing, in the forms of small- to large-scale gatherings and non-essential travel. Improper

planning or assessment of the risk of transmission during any gathering or travel provides opportunities for the virus to spread. Ongoing analyses evaluating the impact of VOCs in countries suggest that the individual- and community-level PHSM and infection prevention and control (IPC) strategies remain effective, including against current VOCs/VOIs. Suboptimal epidemiological surveillance, testing and contact tracing, isolation of cases and quarantine of contacts, and waning support and adherence to PHSM, are currently undoing gains made to date in controlling the pandemic.

Finally, supply shortages in vaccines, medical oxygen, personal protective equipment, laboratory tests, and other critical items continue to present key challenges in responding to the pandemic in the worst-affected countries. In 2021, maintaining the COVID-19 Supply Chain System has taken on an added dimension of complexity, given the requirement for ultra-cold-chain storage from production facilities to points of vaccine administration for some of the COVID-19 vaccines. In addition to the supply chain, the U\$1.96 billion COVID-19 Strategic Preparedness and Response Plan for 2021 still has a 67% funding gap, straining resources for other urgent priorities such as vaccine deployment, epidemiological surveillance, contact tracing, and maintaining essential health services.

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As these risks evolve, WHO will continue to update lists of global VOIs and VOCs to support setting priorities for surveillance and research, and ultimately guide response strategies (for more information, please see the [Tracking SARS-CoV-2 variants](#) website).

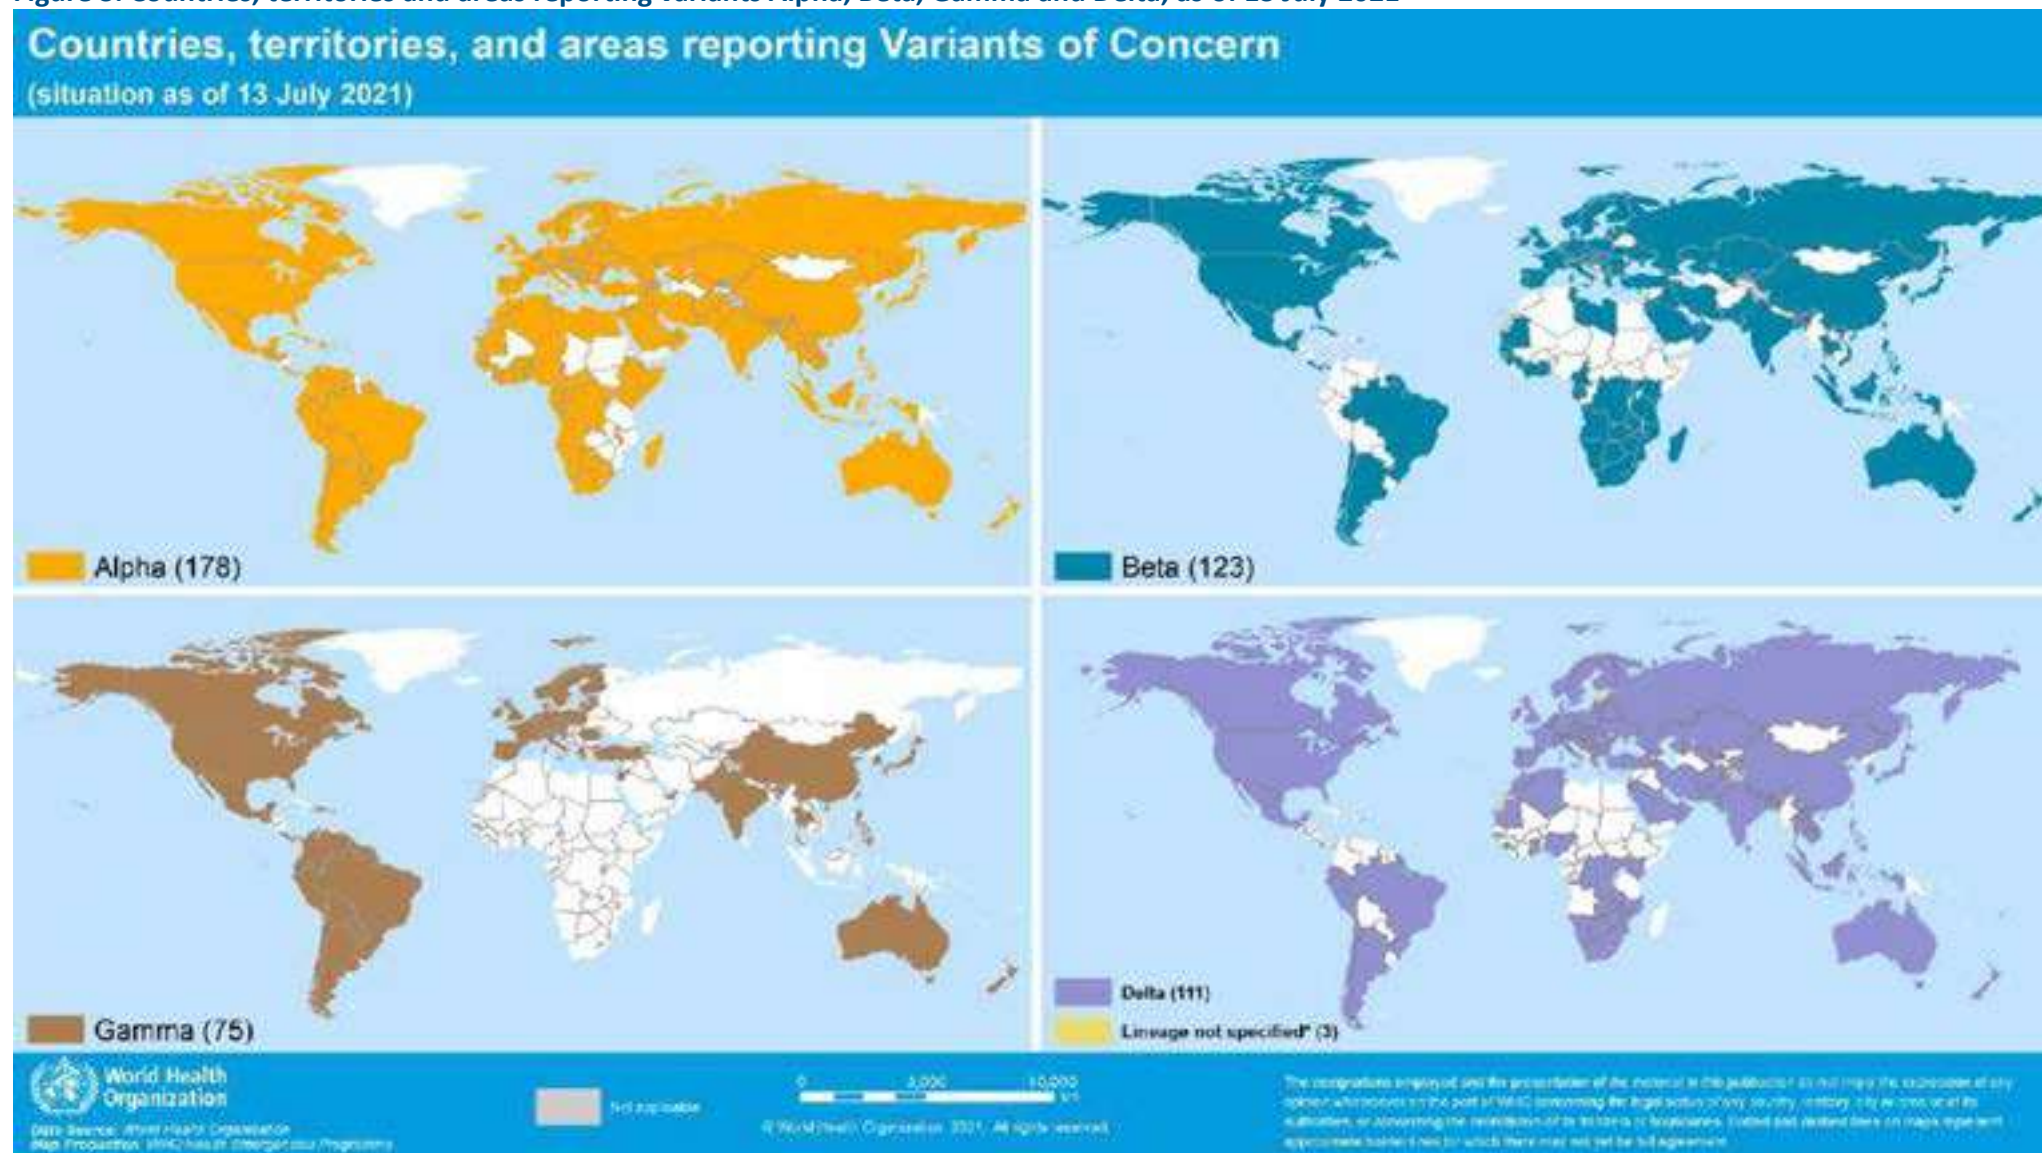

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs has continued to increase (Figure 3, Annex 2). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries. Nevertheless, an overall rise in COVID-19 cases due to the Delta variant is reported across all WHO regions. As of 13 July, at least 111 countries, territories and areas have reported detection of Delta variant, and this is expected to continue to increase, becoming the dominant variant globally in the coming months. The increased transmissibility associated with the Delta variant is likely to result in substantial increases in case incidence and greater pressure on healthcare systems, particularly in contexts of low vaccine coverage.

As countries gradually resume non-essential international travel, the introduction of risk mitigation measures aiming to reduce travel-associated exportation, importation and onward transmission of SARS-CoV-2 should be based on thorough risk assessments conducted systematically and routinely.

Figure 3. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 13 July 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

WHO regional overviews - Epidemiological week 5 – 11 July 2021

African Region

The weekly case incidence and deaths continues to increase for the past consecutive nine weeks and eight weeks, respectively. The African Region reported over 213 000 new cases and over 5000 new deaths, a 5% and a 50% increase respectively as compared to the previous week. In the past week, 62% of all new cases and 53% of all new deaths were reported from South Africa. The highest numbers of new cases were reported from South Africa (132 986 new cases; 224.2 new cases per 100 000 population; percentage difference similar to last week), Zimbabwe (13 188 new cases; 88.7 new cases per 100 000; a 72% increase), and Zambia (12 302 new cases; 66.9 new cases per 100 000; a 25% decrease).

The highest numbers of new deaths were reported from South Africa (2631 new deaths; 4.4 new deaths per 100 000 population; a 52% increase), Uganda (897 new deaths; 2.0 new deaths per 100 000; a 176% increase), and Zambia (378 new deaths; 2.1 new deaths per 100 000; a 12% decrease).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 962 000 new cases and over 23 000 new deaths, a 3% and an 11% decrease respectively as compared to the previous week. Overall, cases continue to decline in the region, however, large increases in case incidence were reported in small islands such as British Virgin Islands, Martinique, Barbados and Turks and Caicos Islands. The highest numbers of new cases were reported from Brazil (333 030 new cases; 156.7 new cases per 100 000; a 9% decrease), Colombia (174 320 new cases; 342.6 new cases per 100 000; a 15% decrease), and the United States of America (128 482 new cases; 38.8 new cases per 100 000; a 38% increase).

The highest numbers of new deaths were reported from Brazil (9736 new deaths; 4.6 new deaths per 100 000; a 10% decrease), Colombia (4008 new deaths; 7.9 new deaths per 100 000; a 9% decrease), and Argentina (2849 new deaths; 6.3 new deaths per 100 000; a 16% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported just under 307 000 new cases and over 3700 new deaths, a 25% and a 7% increase respectively as compared to the previous week. This is the fourth consecutive week of increase in cases reported in the region. The highest numbers of new cases were reported from the Islamic Republic of Iran (114 749 new cases; 136.6 new cases per 100 000; a 38% increase), Iraq (56 535 new cases; 140.6 new cases per 100 000; a 29% increase), and Tunisia (52 076 new cases; 440.6 new cases per 100 000; a 47% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1067 new deaths; 1.3 new deaths per 100 000; a 16% increase), Tunisia (983 new deaths; 8.3 new deaths per 100 000; a 44% increase), and Afghanistan (525 new deaths; 1.3 new deaths per 100 000; a 4% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

Cases in the European Region have been steadily increasing over the past month and this week, the Region reported over 653 000 new cases, a 20% increase as compared to the previous week. The number of new deaths reported regionally this week was similar to that of the previous week. The highest numbers of new cases were reported from the United Kingdom (210 277 new cases; 309.8 new cases per 100 000; a 30% increase), Russian Federation (172 392 new cases; 118.1 new cases per 100 000; an 8% increase), and Spain (52 824 new cases; 111.6 new cases per 100 000; a 19% decrease).

The highest numbers of new deaths were reported from the Russian Federation (5077 new deaths; 3.5 new deaths per 100 000; a 9% increase), Turkey (318 new deaths; 0.4 new deaths per 100 000; a 9% decrease), and Germany (201 new deaths; 0.2 new deaths per 100 000; a 27% decrease).

Updates from the [European Region](#)

South-East Asia Region

Although trends in the incidence of new cases in the South-East Asia Region are at much lower levels as compared to the region's highest peaks at the start of May, the Region is reporting another resurgence in cases with over 712 000 new cases reported in the Region this week, a 16% increase as compared to the previous week. More concerning is the number of new deaths: the past week saw over 14 000 new deaths, a 26% increase as compared to the previous week. The highest numbers of new cases were reported from India (291 789 new cases; 21.1 new cases per 100 000; a 7% decrease), Indonesia (243 119 new cases; 88.9 new cases per 100 000; a 44% increase), and Bangladesh (76 272 new cases; 46.3 new cases per 100 000; a 35% increase).

The highest numbers of new deaths were reported from India (6035 new deaths; 0.4 new deaths per 100 000; a 4% decrease), Indonesia (5882 new deaths; 2.2 new deaths per 100 000; a 71% increase), and Bangladesh (1354 new deaths; 0.8 new deaths per 100 000; a 52% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region has reported increasing trends in case incidence for the past three weeks although deaths remain relatively stable. This week over 147 000 new cases and over 1800 new deaths were reported, a 15% increase and a 3% decrease respectively as compared to the previous week. The highest numbers of new cases were reported from Malaysia (54 584 new cases; 168.6 new cases per 100 000; a 24% increase), the Philippines (36 706 new cases; 33.5 new cases per 100 000; a 5% decrease), and Japan (13 314 new cases; 10.5 new cases per 100 000; a 22% increase).

The highest numbers of new deaths were reported from the Philippines (753 new deaths; 0.7 new deaths per 100 000; an 8% decrease), Malaysia (633 new deaths; 2.0 new deaths per 100 000; a 15% increase), and Cambodia (185 new deaths; 1.1 new deaths per 100 000; a 7% increase).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the media briefing on COVID-19 – 7 July 2021](#), the Director-General highlighted:
 - the need for vaccinating 10 per cent of people in all countries by September and 40 per cent by the end of the year to position the world on the path to vaccinating 70 percent of the people in all countries by the middle of 2022.
 - the use of Interleukin-6 receptor blockers in patients who are severely or critically ill with COVID-19, a class of medicines that is lifesaving, especially when administered alongside corticosteroids.
- In his introductory remarks at the high-level event: [Impact of violence on children's mental health- 8 July 2021](#), the Director-General emphasized the need to step up the efforts to improve the prevention, diagnoses and treatment of mental health conditions in children, and the need for building nurturing environments within families, schools and communities for children to achieve the right to be free from violence and enjoy high quality mental healthcare.

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

from official sources.

ation become available.

** Unspecified B.1.617 were excluded for Nigeria, Cyprus and North Macedonia this week based on further information.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Excludes countries, territories, and areas that have never reported the detection of a variant of concern

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions except, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 47, published 6 July 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 4 July 2021

Globally, after a decline in newly reported cases for seven consecutive weeks, there has been a slight increase in new weekly cases in the last two weeks, with over 2.6 million cases reported last week (28 June – 4 July 2021) as compared to the previous week (Figure 1). The number of weekly deaths continued to decrease, with just under 54 000 deaths reported in the past week, a 7% decrease as compared to the previous week. This is the lowest weekly mortality figure since early October 2020. The cumulative number of cases reported globally now exceeds 183 million and the number of deaths is almost 4 million.

This week, all Regions except the Americas reported an increase in new cases. The European Region reported a sharp increase in incidence (30%) whereas the African region reported a sharp increase in mortality (23%) as compared to the previous week (Table 1). All Regions, with the exception of the Americas and South-East Asia Regions, reported an increase in the number of deaths in the past week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 4 July 2021**

**See [Annex 2: Data, table and figure notes](#)

The highest numbers of new cases were reported from Brazil (364 709 new cases; 30% decrease), India (312 250 new cases; 11% decrease), Colombia (204 556 new cases; similar to last week), Indonesia (168 780 new cases; 35% increase), and the United Kingdom (161 805 new cases; 67% increase). Over the past week, the highest numbers of new cases per 100 000 population were reported from Seychelles (758 new cases per 100 000 population), Mongolia (472 new cases per 100 000 population), Colombia (402 new cases per 100 000 population), Namibia (367 new cases per 100 000 population) and Cyprus (324 new cases per 100 000 population).

Globally, cases of the Alpha variant have been reported in 173 countries, territories or areas (hereafter countries; one new country in the past week), Beta in 122 countries (three new countries), Gamma in 74 countries (two new countries) and Delta in 104 countries (7 new countries).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 4 July 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	992 023 (37%)	-13%	72 804 991 (40%)	26 721 (50%)	-11%	1 914 473 (48%)
Europe	505 790 (19%)	30%	56 235 850 (31%)	6 926 (13%)	6%	1 189 019 (30%)
South-East Asia	612 933 (23%)	7%	35 219 144 (19%)	11 542 (21%)	-12%	495 939 (12%)
Eastern Mediterranean	245 740 (9%)	11%	11 133 173 (6%)	3 479 (6%)	2%	218 804 (6%)
Africa	204 012 (8%)	15%	4 172 433 (2%)	3 359 (6%)	23%	97 682 (2%)
Western Pacific	128 063 (5%)	10%	3 631 664 (2%)	1 931 (4%)	7%	55 757 (1%)
Global	2 688 561 (100%)	3%	183 198 019 (100%)	53 958 (100%)	-7%	3 971 687 (100%)

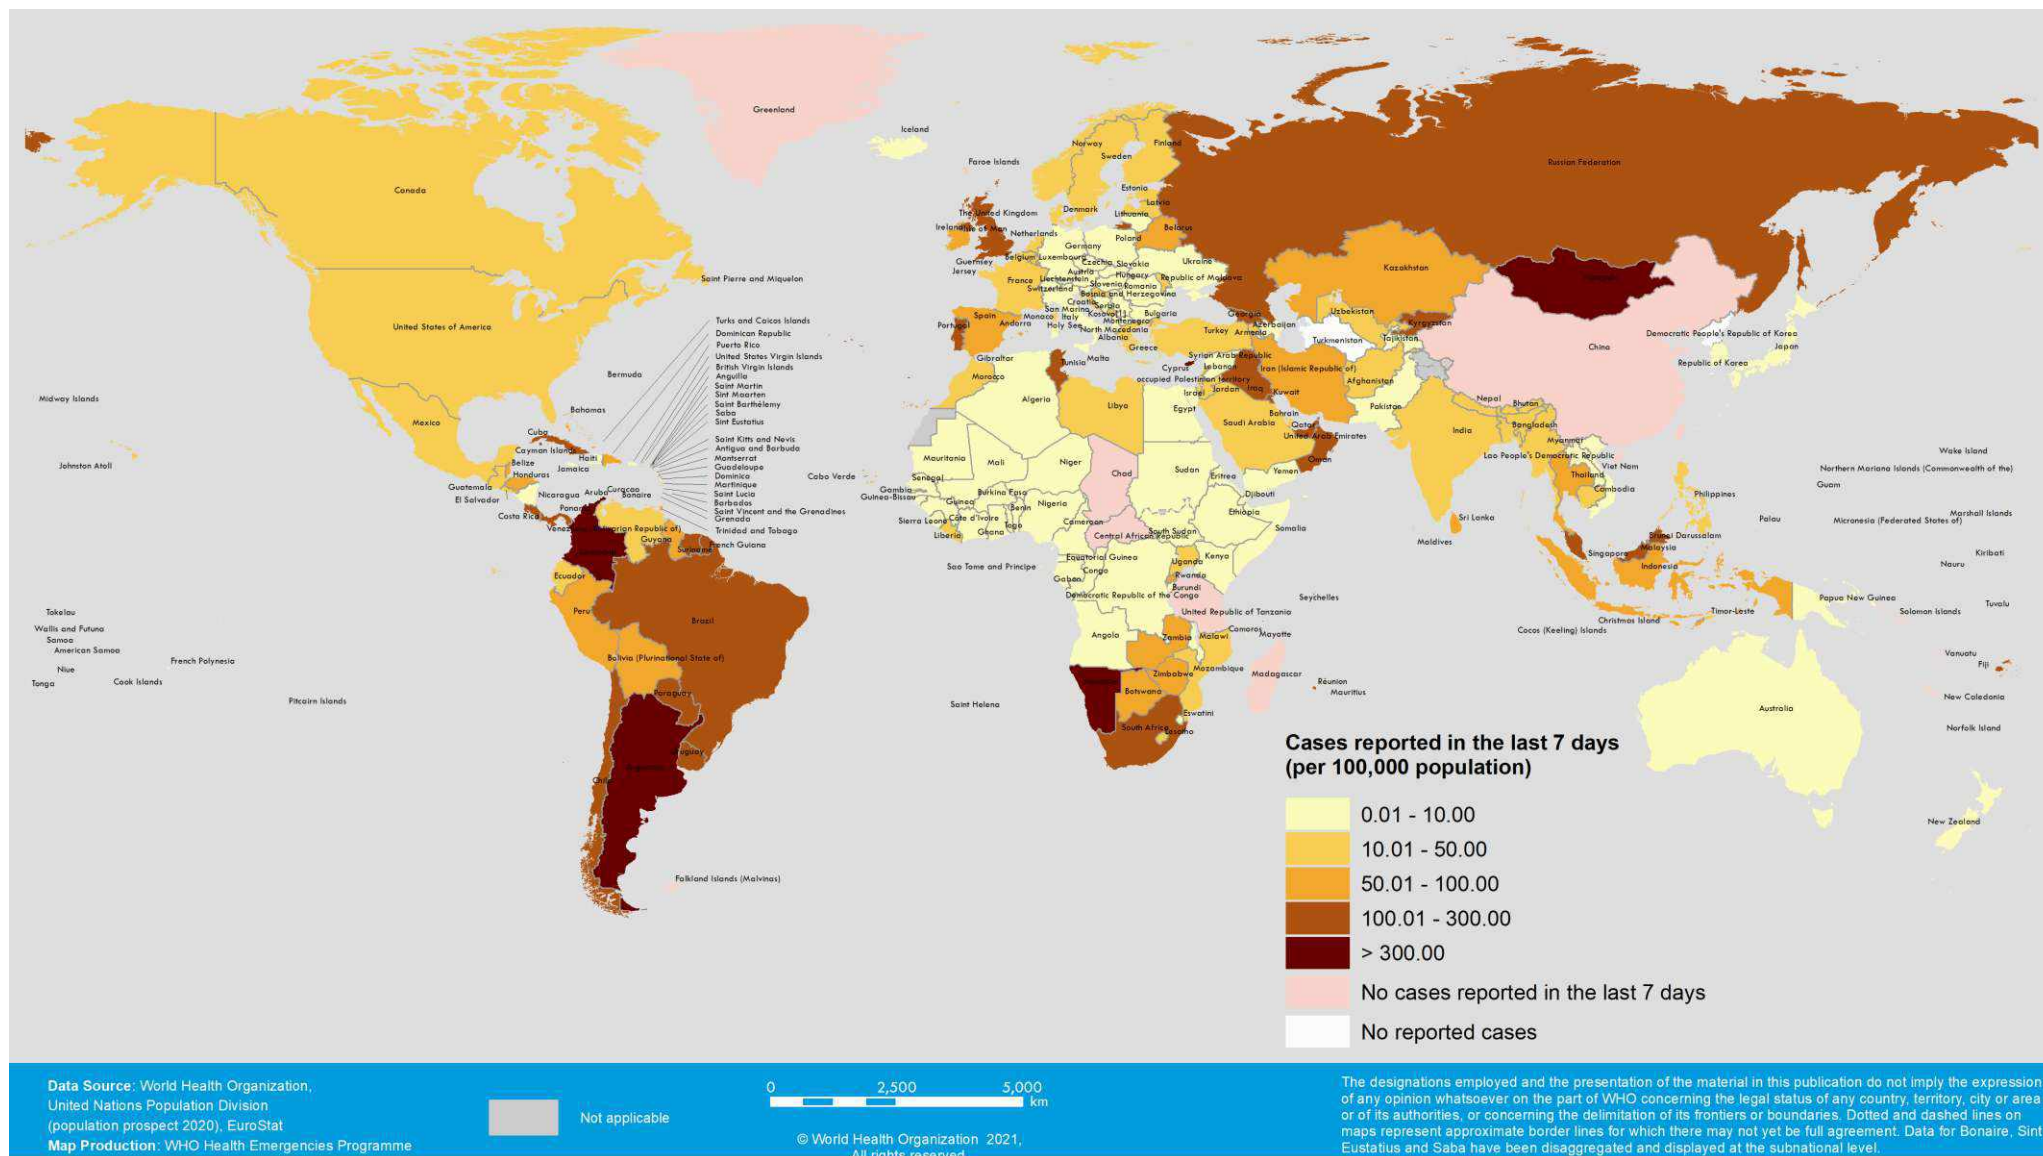

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

**See Annex 2: Data, table and figure notes

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants. Here we provide updates on:

- Variant working definitions, and other variants and amino acid changes under monitoring
- Updates to the variant classifications
- Countries/territories/areas reporting the detection of VOCs

Variant working definitions, and other variants and amino acid changes under monitoring

Given the ongoing evolution in our understanding of the impacts of VOCs and VOIs, and the requirements for surveillance and response, WHO periodically reviews and adjusts working definitions (see Box 1 and [WHO Tracking SARS-CoV-2 Variants website](#)).

The revised set of definitions additionally formalizes a third category labelled ‘Alerts for Further Monitoring’, which includes variants with indications that they may pose a risk to global public health, depending on the evolving pandemic, but for which evidence of phenotypic or epidemiological impacts are less clear when compared to the listed VOCs or VOIs. These Alerts are reassessed regularly against criteria outlined in the VOI/VOC working definitions.

Box 1: SARS-CoV-2 Variant Working Definitions, last updated 6 July

Variant of Concern

A SARS-CoV-2 variant that meets the definition of a VOI (see below) and, through a comparative assessment, has been demonstrated to be associated with one or more of the following changes at a degree of global public health significance:

- Increase in transmissibility or detrimental change in COVID-19 epidemiology; OR
- Increase in virulence or change in clinical disease presentation; OR
- Decrease in effectiveness of public health and social measures or available diagnostics, vaccines, therapeutics.

Variant of Interest

A SARS-CoV-2 variant:

- with genetic changes that are predicted or known to affect virus characteristics such as transmissibility, disease severity, immune escape, diagnostic or therapeutic escape; AND
- Identified to cause significant community transmission or multiple COVID-19 clusters, in multiple countries with increasing relative prevalence alongside increasing number of cases over time, or other apparent epidemiological impacts to suggest an emerging risk to global public health.

Alerts for Further Monitoring

A SARS-CoV-2 variant with genetic changes that are suspected to affect virus characteristics with some indication that it may pose a future risk, but evidence of phenotypic or epidemiological impact is currently unclear, requiring enhanced monitoring and further assessment pending new evidence.

See also the [WHO Tracking SARS-CoV-2 Variants website](#) for the latest working definitions, and currently designated VOCs, VOIs and Alerts for Further Monitoring, and further information.

In addition to these alerts, reported detections of VOCs with additional amino acid changes, which may or may not carry increased risk of additional phenotypic impacts, are being regularly assessed – e.g., Delta with K417N mutation or Alpha with E484K mutation. Notably, all variants, including VOCs and VOIs, are expected to continue to evolve over time given the ongoing high rates of transmission globally. A phenomenon whereby variants independently acquire the same or similar amino acid substitutions that may offer a competitive advantage (also known as convergent evolution) has been repeatedly observed over the course of the pandemic. Where there is evidence of a common constellation of amino acid changes that have sufficiently diverged from the parent VOC lineage, such sequences may be reclassified under Pango into sublineages to support ongoing investigations, tracking and scientific discourse. While it remains important to track and better understand the impacts of these variants, to date VOCs with additional notable amino acid changes comprise a small fraction of the total number of sequenced cases, and there remains limited direct evidence of further phenotypic impacts.

It is expected that our understanding of designated ‘Alerts for Further Monitoring’, VOCs with notable amino acid changes (including established sublineages) will evolve over time, and variants may be readily added/removed from these characterizations. WHO will, therefore, not be designating labels for these two categories of variants at this time, but where appropriate refer to these cases by their parent lineages (e.g., Delta includes B.1.617.2, AY.1, and AY.2; or Alpha (Pango lineage B.1.1.7; GISAID clade GRY (formerly GR/501Y.V1); Nextstrain clade 20I (V1)) includes B.1.1.7 with E484K. If these variants demonstrate changes in virus characteristics, compared to the parent lineage, in the future, and as such, are assessed as independently meeting the VOC or VOI definitions, then labels will be assigned accordingly.

Updates to the variant classifications

As the global public health risks posed by specific SARS-CoV-2 variants becomes better understood, WHO will continue to update the list of global VOIs and VOCs (Table 2) to support setting priorities for surveillance and research, and ultimately guide response strategies. These updates reflect emergence of new variants, changing epidemiology, and our evolving understanding of the phenotypic impacts of variants as new evidence becomes available. A previously designated Variant of Interest (VOI) or Variant of Concern (VOC) which has conclusively demonstrated to no longer pose a major added risk to global public health compared to other circulating SARS-CoV-2 variants, can be reclassified.

Based upon the latest round of assessments, VOIs Epsilon (B.1.427/B.1.429), Zeta (P.2), and Theta (P.3) were reclassified as ‘Alerts for further monitoring’. While all three variants carry mutations with suspected and/or established phenotypic impacts, reported detections of these variants have decreased over time, suggesting a decline in their respective incidence worldwide, and diminishing public health risks relative to other VOCs and VOIs. Importantly, this assessment considers primarily global risks posed by these variants, and national authorities may choose to continue to designate these as variants of local interest/concern. Moreover, these variants will continue to be monitored, and if new evidence of impacts emerges, their classification will be reassessed.

Epsilon (B.1.427/B.1.429) has been associated with increased transmissibility, a modest decrease in susceptibility to some antibody treatments, and reduced neutralization by convalescent and post-vaccination sera.¹ As of 6 July, just under 50 000 sequences have been uploaded to GISAID from 45 countries.² Worldwide prevalence among sequenced samples has declined from 5% at peak in early February, to less than 0.5% of samples in recent months.³ The vast majority of worldwide sequences (98%) were reported from the United States of America, where Epsilon has been progressively displaced by the emergence of Alpha, Gamma, Delta and other variants, and contributed <0.2% of sequenced samples collected during the weeks two weeks ending 19 June.⁴ Moreover, available data suggest vaccines and treatments remain effective; prompting the Centers for Disease Prevention and Control to reclassify Epsilon from a local VOC on 29 June.¹

Zeta (P.2) harbours spike amino acid change E484K, which has been implicated in resistant to neutralizing antibodies; however, lacks the constellation of mutations synonymous with other VOCs and VOIs. It emerged during October 2020 concomitantly to an increase in case incidence in parts of South America, suggesting a potential increase risk. The global prevalence of samples sequenced as Zeta has remained relatively low and progressively declined to very low levels (<0.5%) from March 2021. As of 6 July, 4439 sequences have been uploaded to GISAID from 42 countries. Half of global sequences (52%, n=2319) originate from Brazil, where prevalence peaked at ~55% in early January 2021. Following the emergence and dominance of VOC Gamma (P.1) in Brazil, prevalence of Zeta has fell to <2% of sequenced samples during April 2021 and has continued to decline.⁵

Theta (P.3) harbours several amino acid changes suggestive of increased resistance to neutralizing antibodies and is potentially more transmissible; however, overall detections of this variant have remained relatively low to date. As to 6 July, a total of 269 sequences were uploaded to GISAID from 14 countries. Most of these sequences (71%, n=191) were reported from the Philippines; predominantly in the Central Visayas Region, where a cluster of cases was identified earlier this year.² Globally over the past 3 months, only sporadic detections or small clusters of cases have been reported.

Updated working definitions, summary table of VOCs and VOIs, and a list of Alerts for Further Monitoring, are available on the [WHO Tracking SARS-CoV-2 Variants website](#).

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase (Figure 2, Annex 1). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs is summarized in Table 3, as well as in [previous editions](#) of these COVID-19 Weekly Epidemiological Updates. Since the last detailed [update](#) on 22 June, new evidence has been published on the phenotypic characteristics of the Delta variant. Based on the estimated transmission advantage of the Delta variant, it is expected that Delta will rapidly outcompete other variants and become the dominant circulating lineage over the coming months.⁶ Based on global data submitted to GISAID, the estimated effective reproductive number for the Delta variant is 55% (95%CI 43-68%) higher than the Alpha variant and 97% (95%CI 76-117%) higher relative to non-VOC/VOI.

In the European Region, based on the estimated transmission advantage of the Delta variant and using modelling forecasts, an estimated 90% of new SARS-CoV-2 infections are expected to be due to Delta by the end of August.⁷ Early data from Scotland, from individuals who tested positive from 1 April to 21 June 2021, showed an increased risk of hospitalization (hazard ratio of hospitalization 1.8; 95%CI 1.4-2.3; data adjusted for age, sex, poverty index, temporal trend, and comorbidities) among cases infected with the Delta variant (as detected by screening of PCR S-gene positive samples), compared with those infected with the Alpha variant (S-gene target failure).⁸

In regards to the Alpha variant, findings from a recent study carried out in 2147 inpatients showed no overall increase in mortality [hazard ratio (HR) 1.01; 95% CI 0.79 – 1.28] or Intensive Therapy Unit (ITU) admission (HR 1.01; 95% CI: 0.75 – 1.37) associated with the Alpha variant as compared to other lineages after adjusting for age, sex, co-morbidities, care home residence, pregnancy and ethnicity. However, an analysis of gender-specific effects of the Alpha variant suggests an increased risk of mortality (HR 1.30; 95% CI: 0.95 – 1.78) and ITU admission (HR 1.82; 95% CI: 1.15 -2.90) in females infected with this variant as compared to other lineages. Males do not show an increased risk of mortality or ITU admission

(mortality HR 0.82, 95% CI 0.61-1.10; ITU HR 0.74, 95% CI 0.52-1.04); this indicates that women may potentially be at an increased risk of admission to ITU and at modestly increased risk of mortality.⁹ Being among the largest studies of hospitalized patients, this study conducted in the United Kingdom provides useful information on disease course and progression, however, analysis of these patients may not provide information on disease severity across all SARS-CoV-2 infections in the population as a whole. Additionally, information on vaccination status for individual patients was not considered in this study.

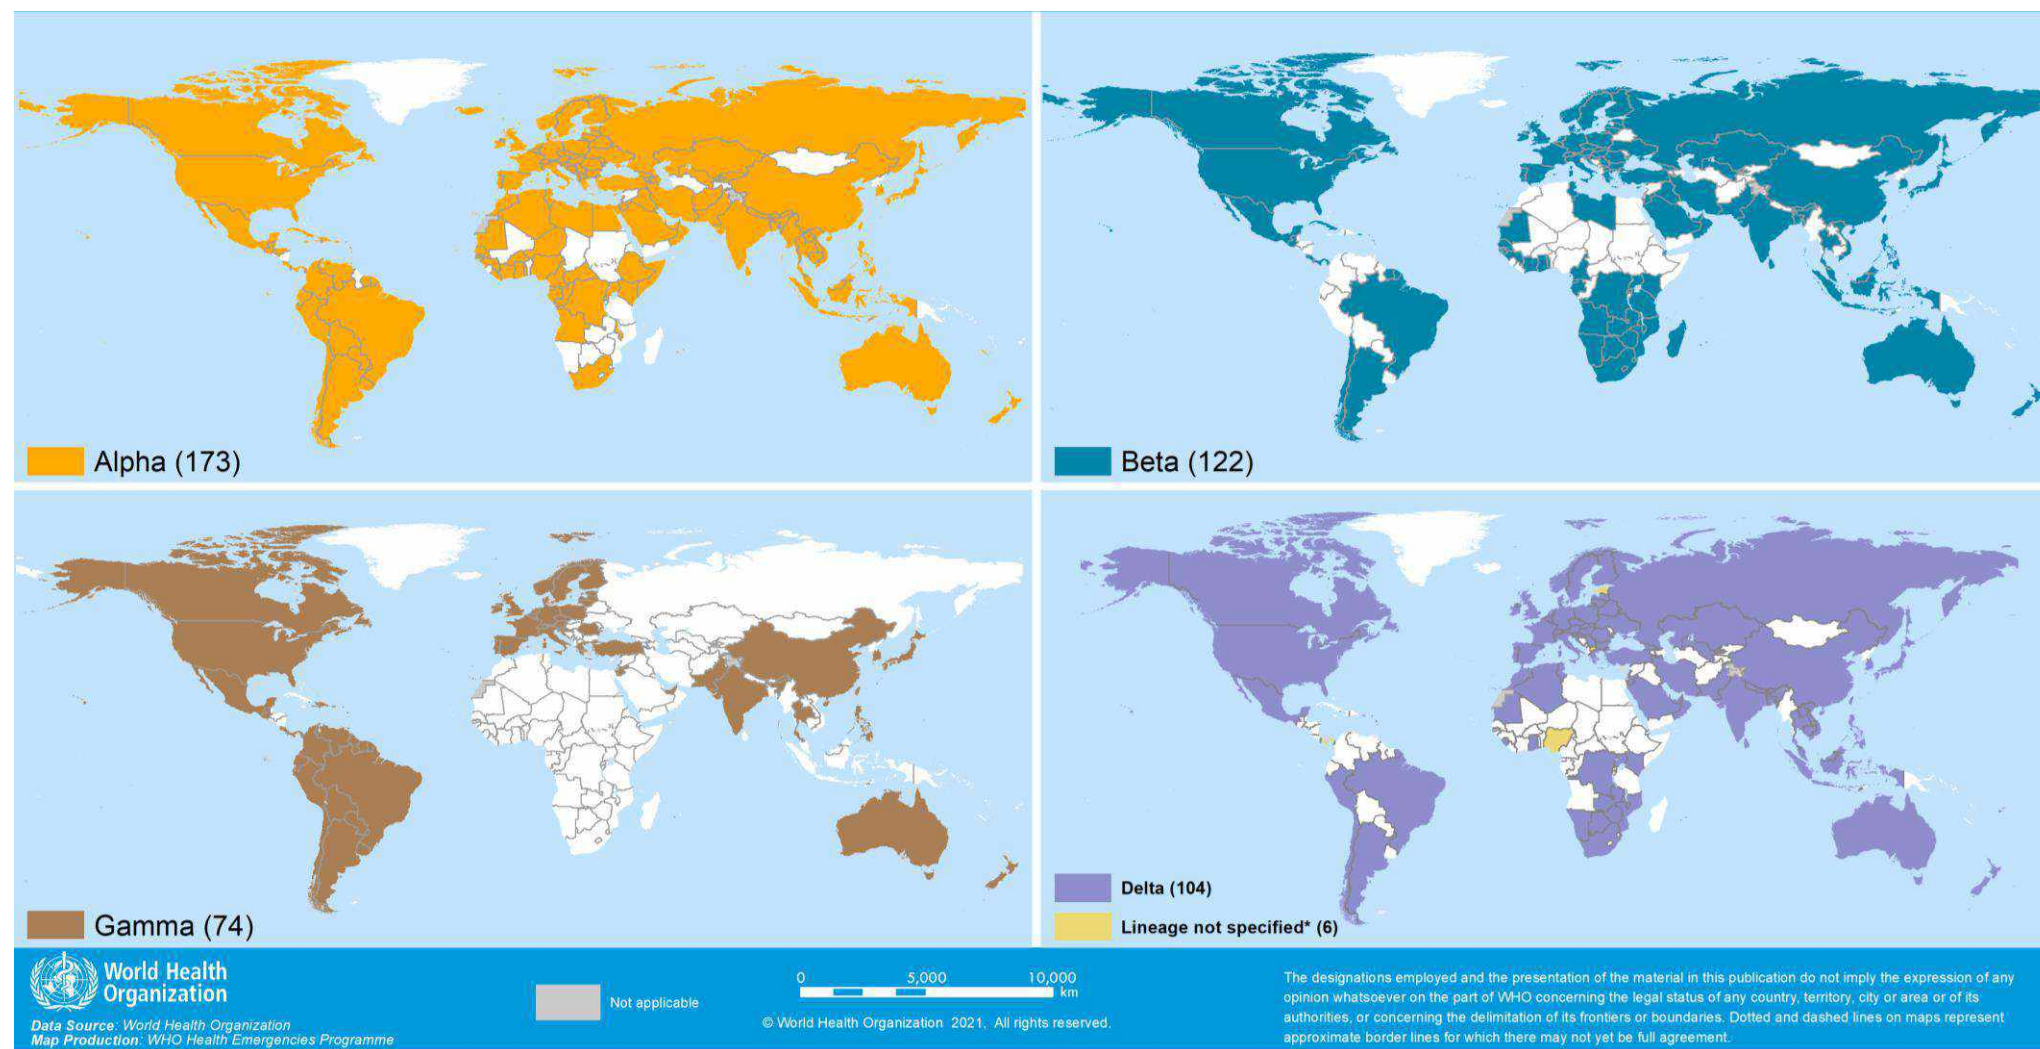

A preprint cohort study conducted in Norway analyzed 1103 unvaccinated individuals hospitalized for COVID-19 from 21 December 2020 to 25 April 2021. Among people infected with the Alpha variant, there was no difference in the length of stay in the hospital or ICU, and no significant difference in mortality up to 30 days following discharge as compared to those infected with non-VOCs.¹⁰ This suggests that, while Alpha may increase the risk of hospitalization, other characteristics such as age and underlying risk factors likely influence the hospitalized patients' clinical course and the type of healthcare required.^{10,11}

Table 3: Summary of phenotypic impacts* of Variants of Concern

WHO label	Alpha	Beta	Gamma	Delta
Transmissibility	Increased transmissibility and secondary attack rate ¹²	Increased transmissibility ¹³	Increased transmissibility ¹⁴	Increased transmissibility and secondary attack rate ^{6,15,16}
Disease severity	Increased risk of hospitalization ¹⁷ , possible increased risk of severity and mortality ¹⁸	Not confirmed, possible increased risk of in-hospital mortality ^{19,20}	Not confirmed, possible increased risk of hospitalization ²¹	Not confirmed, possible increased risk of hospitalization ²²
Risk of reinfection	Neutralizing activity retained, ²³ risk of reinfection remains similar ^{24,25}	Reduction in neutralizing activity reported; T cell response elicited by D614G virus remains effective ²⁶⁻²⁹	Moderate reduction in neutralizing activity reported ^{30,31}	Reduction in neutralizing activity reported ³²
Impacts on diagnostics	Limited impact – S gene target failure (SGTF); no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed ³³	No impact on RT-PCR or Ag RDTs observed ¹⁶	None reported to date	None reported to date

**Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 6 July 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

VOC impacts on vaccines

Table 4 summarises the impact of variants on vaccine efficacy/effectiveness (VE) and quantifies the reduction in VE due to variants compared to VE in non-VOC settings. Of note, reductions in VE do not mean loss of protection, as indicated by the absolute VE estimate. For example, a 10 percent point reduction in VE against symptomatic disease for mRNA vaccines would still mean high vaccine effectiveness of ~85%. In addition, vaccines have shown higher VE against severe disease; thus, small reductions in VE against severe disease due to VOCs may still mean good protection, as is the case for AstraZeneca-Vaxzevria.

Since the 22 June [update](#), phase 3 trial results for Bharat-Covaxin (not yet peer-reviewed) have been made available. This double-blind, randomized control trial included 25 798 participants aged 18 years and older, randomized to receive two doses of the vaccine or a placebo with 4 weeks in between doses. Overall vaccine efficacy against severe and symptomatic disease ≥ 14 days post second dose was 93.4% (95% CI: 57.1-99.8%) and 77.8% (65.2-86.4%), respectively. Among 130 SARS-CoV-2 positive samples, 79 (60.8%) were genotyped. VE against Delta symptomatic disease (65.2% (33.1-83.0%)) was lower than other typed variants; 90.1% (30.4-99.8%) against Kappa (B.1.617.1), and 73.0% (-2.2-95.2%) against all other variants, although numbers were small with overlapping confidence intervals.³⁴

A test-negative case-control study in Ontario, Canada (not yet peer reviewed) assessed the effectiveness against variants of concern among 421 073 individuals aged 16 years and older, who were tested for SARS-CoV-2. The authors used a combination of whole genome sequencing and mutation screening by PCR to classify VOC. VE of two doses of both Pfizer BioNTech-Comirnaty and Moderna-mRNA-1273 against symptomatic disease ≥ 7 days post final dose was measured. VE for Pfizer BioNTech-Comirnaty was 93% (95% CI: 88-96%), 89% (86-91%), 84% (69-92%), and 87% (64-95%) against non-VOC, Alpha, Beta/Gamma, and Delta variants, respectively. VE of Moderna-mRNA-1273 was 92% (86-96%) against Alpha as compared to 89% (65-96%) against non-VOC (VE against Beta/Gamma and Delta not measured). A single dose of AstraZeneca-Vaxzevria resulted in a VE of 64-67% for non-VOC, Alpha and Delta, and a VE of 48% against Beta/Gamma. Two dose VE estimates for AstraZeneca-Vaxzevria were not provided due to insufficient numbers. The study also found two doses of Pfizer BioNTech-Comirnaty and Moderna-mRNA-1273 vaccines to provide very good protection against hospitalization or death due to Alpha and non-VOC (VE estimates of 94-96%), and two doses of Pfizer BioNTech-Comirnaty also had high VE against Beta/Gamma (95%); no data for Moderna-mRNA-1273 against Beta/Gamma. A single dose of Pfizer BioNTech-Comirnaty, Moderna-mRNA-1273 and AstraZeneca-Vaxzevria prevented 78%, 96% and 88% of hospitalizations/deaths due to Delta, respectively.³⁵

Another study (not yet peer-reviewed) reported on the effectiveness of Sinovac-CoronaVac in Manaus, Brazil, during a time when the predominant circulating strain was Gamma (86% of genotyped SARS-CoV-2 were the Gamma variant during the peak of the epidemic in Manaus). The study used a test-negative case-control design to estimate VE among ~400 case-control pairs of health care workers. VE of two doses of the vaccine against symptomatic disease and against infection 14+ days post final dose was 36.8% (95% CI: -54.9-74.2%) and 37.9% (95% CI: -46.4 to 73.6%), respectively. Authors note the low VE estimate likely reflect a bias towards the null hypothesis as suggested by the finding that vaccinated individuals were much more likely to be infected than unvaccinated individuals in the period 0-13 days after receipt of the first dose (aOR 2.11, 95% CI 1.36-3.27). Authors also note that the analysis may have been underpowered to be able to detect a VE of lower than 70%.³⁶

Four new studies (not yet peer reviewed) have evaluated the ability of vaccine sera to neutralize the Delta variant. While these four studies found relatively modest reductions in neutralization of the Delta variant by AstraZeneca-Vaxzevria (4.0-fold reduction), SII-Covishield (3.2-fold reduction), Moderna-mRNA-1273 (2.1-fold reduction), and Janssen-Ad26.COV 2.5 (1.6-fold reduction) relative to the reference strain, a larger reduction was found for the Pfizer BioNTech-Comirnaty (11.3-fold reduction) in one of the studies.³⁷⁻⁴⁰ To date, five studies have evaluated neutralization of the Delta variant by Pfizer BioNTech-Comirnaty and report fold-reductions ranging from 1.4 to 11.3; two studies evaluating AstraZeneca-Vaxzevria have both reported an approximate 4-fold reduction; and single studies have found ~2-3-fold reductions by sera from individuals who had received Janssen-Ad26.COV 2.5, Moderna-mRNA-1273, Bharat-Covaxin, and SII-Covishield vaccines.³⁷⁻⁴⁶

Arrows generalize the magnitude of reduction in VE or neutralization: “↔” <10% reduction in VE, or VE >90% with no comparator, or that there was a <2-fold reduction in neutralization; “↓” 10 to <20% reduction in VE, or 2 to <5-fold reduction in neutralization; “↓↓” 20 to <30% reduction in VE, or 5 to <10-fold reduction in neutralization; “↓↓↓” ≥30% reduction in VE, or ≥10-fold reduction in neutralization. When more than one neutralization study is available, the interquartile range (25th and 75th percentiles) of fold-reductions across all studies for specific vaccine/variant was used.

The number of studies is shown in parentheses.

“Moderna-mRNA-1273/Pfizer BioNTech-Comirnaty” indicates that both vaccines were evaluated together in study.

Additional notes on VOC impacts on vaccines

- Studies presenting VOC specific VE estimates are assessed against a comparator VE estimate to determine level of reduction in VE. For symptomatic disease, VOC VE is compared against phase 3 randomised RCT results from non-VOC settings. For severe disease and infection, VOC VE is compared to non-VOC VE estimates from the same study when available (or to Alpha VE from same study when assessing Beta, Gamma, or Delta); with an exception for AstraZeneca Vaxzevria for severe disease (phase 3 RCT efficacy estimates against severe disease are used as comparator since within study comparator is unavailable) and for infection (phase 3 estimate of VE against infection due to non-VOC is available and used as comparator). In some instances, a study may be included for severe disease or infection even without a comparator if very high VE estimate against a VOC is reported (i.e., >90%).
- It is also important to note that studies vary in population, outcome definitions, study design and other methodological considerations, which may in part explain differences when comparing VE estimates between different studies. In addition, the reductions presented consider VE point estimates only and do not take into account the uncertainty around these estimates. The reductions in VE noted should be interpreted with these limitations in mind.

WHO regional overviews - Epidemiological week 28 June-4 July 2021

African Region

The African Region reported over 204 000 new cases and over 3300 new deaths, a 15% and a 23% increase respectively as compared to the previous week. For the sixth consecutive week, the region continues to show a marked increase in weekly case incidence and mortality; the Southern and Eastern parts of Africa remain the most affected areas on the continent. The highest numbers of new cases were reported from South Africa (132 450 new cases; 223.3 new cases per 100 000 population; a 28% increase), Zambia (16 456 new cases; 89.5 new cases per 100 000; a 14% decrease), and Namibia (9342 new cases; 367.7 new cases per 100 000; a 28% decrease).

The highest numbers of new deaths were reported from South Africa (1729 new deaths; 2.9 new deaths per 100 000 population; a 46% increase), Zambia (430 new deaths; 2.3 new deaths per 100 000; a 16% increase), and Uganda (325 new deaths; <1 new deaths per 100 000; a 34% increase).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 992 000 new cases and over 26 000 new deaths, a 13% and an 11% decrease respectively compared to the previous week. The Americas is the only region showing a decrease in both weekly case incidence and mortality. For the first time since October 2020, the region reported under 1 million weekly cases. However, several countries from South America, Central America and the Caribbean are still reporting high case incidence and mortality over the past weeks. The highest numbers of new cases were reported from Brazil (364 709 new cases; 171.6 new cases per 100 000; a 30% decrease), Colombia (204 556 new cases; 402.0 new cases per 100 000; similar to the previous week), and Argentina (137 852 new cases; 305.0 new cases per 100 000; a 5% increase).

The highest numbers of new deaths were reported from Brazil (10 810 new deaths; 5.1 new deaths per 100 000; a 14% decrease), Colombia (4402 new deaths; 8.7 new deaths per 100 000; a 4% decrease), and Argentina (3403 new deaths; 7.5 new deaths per 100 000; a 9% decrease).

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 245 000 new cases and over 3400 new deaths, an 11% and a 2% increase respectively as compared to the previous week. Following more than two months of decrease in weekly case incidence, for the third consecutive week the region showed an increase of case incidence, while mortality remained relatively stable for the past month. The highest numbers of new cases were reported from the Islamic Republic of Iran (83 054 new cases; 98.9 new cases per 100 000; a 17% increase), Iraq (43 979 new cases; 109.3 new cases per 100 000; a 16% increase), and Tunisia (35 452 new cases; 300.0 new cases per 100 000; a 59% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (916 new deaths; 1.1 new deaths per 100 000; a 7% increase), Tunisia (682 new deaths; 5.8 new deaths per 100 000; a 10% increase), and Afghanistan (549 new deaths; 1.4 new deaths per 100 000; a 4% increase).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 505 000 new cases and over 6900 new deaths. Following almost three months of declining trends, the region showed for the second consecutive week an increase in the number of new weekly cases and deaths, a 30% and a 6% increase respectively as compared to the previous week. The highest numbers of new cases were reported from the United Kingdom (161 805 new cases; 238.3 new cases per 100 000; a 67% increase), the Russian Federation (159 650 new cases; 109.4 new cases per 100 000; a 19% increase), and Turkey (36 224 new cases; 43.0 new cases per 100 000; a 7% decrease).

The highest numbers of new deaths were reported from the Russian Federation (4643 new deaths; 3.2 new deaths per 100 000; an 18% increase), Turkey (350 new deaths; <1 new deaths per 100 000; a 13% decrease), and Germany (276 new deaths; <1 new deaths per 100 000; a 25% decrease).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported just under 613 000 new cases and over 11 000 new deaths, a 7% increase and a 12% decrease respectively as compared to the previous week. Following a decreasing trend in weekly case incidence for almost two months, mostly driven by the decrease in cases reported in India, the region showed a slight increase of cases this week. Bangladesh, Indonesia, Myanmar and Thailand continue to report large increases in the number of newly reported cases and deaths for this week.

The highest numbers of new cases were reported from India (312 250 new cases; 22.6 new cases per 100 000; an 11% decrease), Indonesia (168 780 new cases; 61.7 new cases per 100 000; a 35% increase), and Bangladesh (56 511 new cases; 34.3 new cases per 100 000; a 54% increase). The highest numbers of new deaths were reported from India (6254 new deaths; 0.5 new deaths per 100 000; a 31% decrease), Indonesia (3444 new deaths; 1.3 new deaths per 100 000; a 39% increase), and Bangladesh (893 new deaths; 0.5 new deaths per 100 000; a 43% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 128 000 new cases and over 1900 new deaths, a 10% and a 7% increase respectively. Cambodia, Fiji and Malaysia, continue to report increases in both weekly cases and deaths.

The highest numbers of new cases were reported from Malaysia (44 145 new cases; 136.4 new cases per 100 000; an 18% increase), the Philippines (38 507 new cases; 35.1 new cases per 100 000; similar to last week), and Mongolia (15 478 new cases; 472.1 new cases per 100 000; a 4% decrease).

The highest numbers of new deaths were reported from the Philippines (819 new deaths; <1 new deaths per 100 000; a 16% increase), Malaysia (550 new deaths; 1.7 new deaths per 100 000; a 3% increase), and Japan (185 new deaths; <1 new deaths per 100 000; a 28% decrease).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the media briefing on COVID-19 – 2 July 2021](#), the Director-General highlighted two ways for countries to push back against COVID-19 surges. These include:
 - **Strengthening public health and social measures (PHSM)**- including strong surveillance, strategic testing, early case detection, isolation and clinical care- remains critical. Additionally, masking, physical distance, avoiding crowded places and keeping indoor areas well ventilated remain the basis for the response.
 - **Equitable distribution or sharing of resources** such as protective gear, medical oxygen, tests, treatments and vaccines.
- In [his introductory remarks at the event: Gender Equal Health and Care Workforce Initiative - 1 July 2021](#), the Director-General emphasized the need to address gender inequalities as a priority especially when majority of the world's health workers - almost 70% - are women. WHO is committed to advocating for decent and safe work conditions for all health and care workers.

Updates and publications

- **COVID-19 Vaccines and Vaccine Safety**
 - [Ethical Framework for WHO's work in the ACT-Accelerator](#)
 - [Observational Study Protocol Template for sentinel surveillance of adverse events of special interest \(AESIs\) after vaccination with COVID-19 vaccines](#)
- **International Travel**
 - [Technical considerations for implementing a risk-based approach to international travel in the context of COVID-19: Interim guidance, 2 July 2021](#)
 - [Policy considerations for implementing a risk-based approach to international travel in the context of COVID-19, 2 July 2021](#)
- **Essential Health Services**
 - [Implementation guidance for assessments of frontline service readiness: strengthening real-time monitoring of health services in the context of the COVID-19 pandemic, 1 July 2021](#)

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>

**Newly reported in this update.*

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

from official sources.

ation become available.

***Variant Beta for Kyrgyzstan and unspecified B.1.617 for Latvia were excluded this week based on further information received.*

****Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Efforts are ongoing to differentiate these in future reports. Excludes countries, territories, and areas that have never reported the detection of a variant of concern.*

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Global overview

Data as of 27 June 2021

The global number of new cases over the past week (21-27 June 2021) was over 2.6 million, a similar number compared to the previous week (Figure 1). The number of weekly deaths continued to decrease, with more than 57 000 deaths reported in the past week, a 10% decrease as compared to the previous week. This is the lowest weekly mortality figure since those recorded in early November 2020. Globally, COVID-19 incidence remains very high with an average of over 370 000 cases reported each day over the past week. The cumulative number of cases reported globally now exceeds 180 million and the number of deaths is almost 4 million.

This week, the African region recorded a sharp increase in incidence (33%) and mortality (42%) when compared to the previous week (Table 1). The Eastern Mediterranean and European Regions also reported increases in the number of weekly cases. All Regions, with the exception of the African Region, reported a decline in the number of deaths in the past week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 27 June 2021**

**See Annex 2: Data, table and figure notes

The highest numbers of new cases were reported from Brazil (521 298 new cases; 3% increase), India (351 218 new cases; 12% increase), Colombia (204 132 new cases; 5% increase), the Russian Federation (134 465 new cases; 24% increase), and Argentina (131 824 new cases; 11% decrease). Over the past week, the highest numbers of new cases per 100 000 population were reported from Seychelles (708 new cases per 100 000 pop), Namibia (509 new cases per 100 000 pop) and Mongolia (491 new cases per 100 000 pop).

Globally, cases of the Alpha variant have been reported in 172 countries, territories or areas (hereafter countries; two new countries in the past week), of Beta in 120 countries (one new country), Gamma in 72 countries (one new country) and Delta in 96 countries (11 new countries).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 27 June 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 139 518 (44%)	-1%	71 812 677 (40%)	30 120 (52%)	-2%	1 887 752 (48%)
Europe	372 448 (14%)	10%	55 713 043 (31%)	6 435 (11%)	-1%	1 181 135 (30%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or effectiveness of public health and social measures (PHSM) applied by national authorities to control disease spread. “Signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) are detected and assessed based on the risk posed to global public health. As these risks evolve, WHO will update lists of global VOIs and VOCs (Table 2) to support setting priorities for surveillance and research, and ultimately guide response strategies. National authorities may choose to designate other variants of local interest/concern, and are encouraged to investigate and report on impacts of these variants. Here we provide updates on classifications of VOCs and VOIs, as well as the updated countries/territories/areas reporting the detection of VOCs.

Table 2: SARS-CoV-2 Variants of Concern (VOCs) and Variants of Interest (VOIs), as of 29 June 2021

WHO label	Pango lineage	GISAID clade	Nextstrain clade	Earliest documented samples	Date of designation
Variants of Concern (VOCs):					
Alpha	B.1.1.7	GRY (formerly GR/501Y.V1)	20I (V1)	United Kingdom, Sep-2020	18-Dec-2020
Beta	B.1.351	GH/501Y.V2	20H (V2)	South Africa, May-2020	18-Dec-2020
Gamma	P.1	GR/501Y.V3	20J (V3)	Brazil, Nov-2020	11-Jan-2021
Delta	B.1.617.2	G/478K.V1	21A	India, Oct-2020	VOI: 4-Apr-2021 VOC: 11-May-2021
Variants of Interest (VOIs):					
Epsilon	B.1.427/ B.1.429	GH/452R.V1	21C	United States of America, Mar-2020	5-Mar-2021
Zeta	P.2	GR/484K.V2	20B	Brazil, Apr-2020	17-Mar-2021
Eta	B.1.525	G/484K.V3	21D	Multiple countries, Dec-2020	17-Mar-2021
Theta	P.3	GR/1092K.V1	21E	Philippines, Jan-2021	24-Mar-2021
Iota	B.1.526	GH/253G.V1	21F	United States of America, Nov-2020	24-Mar-2021
Kappa	B.1.617.1	G/452R.V3	21B	India, Oct-2020	4-Apr-2021
Lambda	C.37	GR/452Q.V1	20D	Peru, Dec-2020	14-Jun-2021

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs continue to increase (Figure 3, Annex 1). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

WHO recommendations

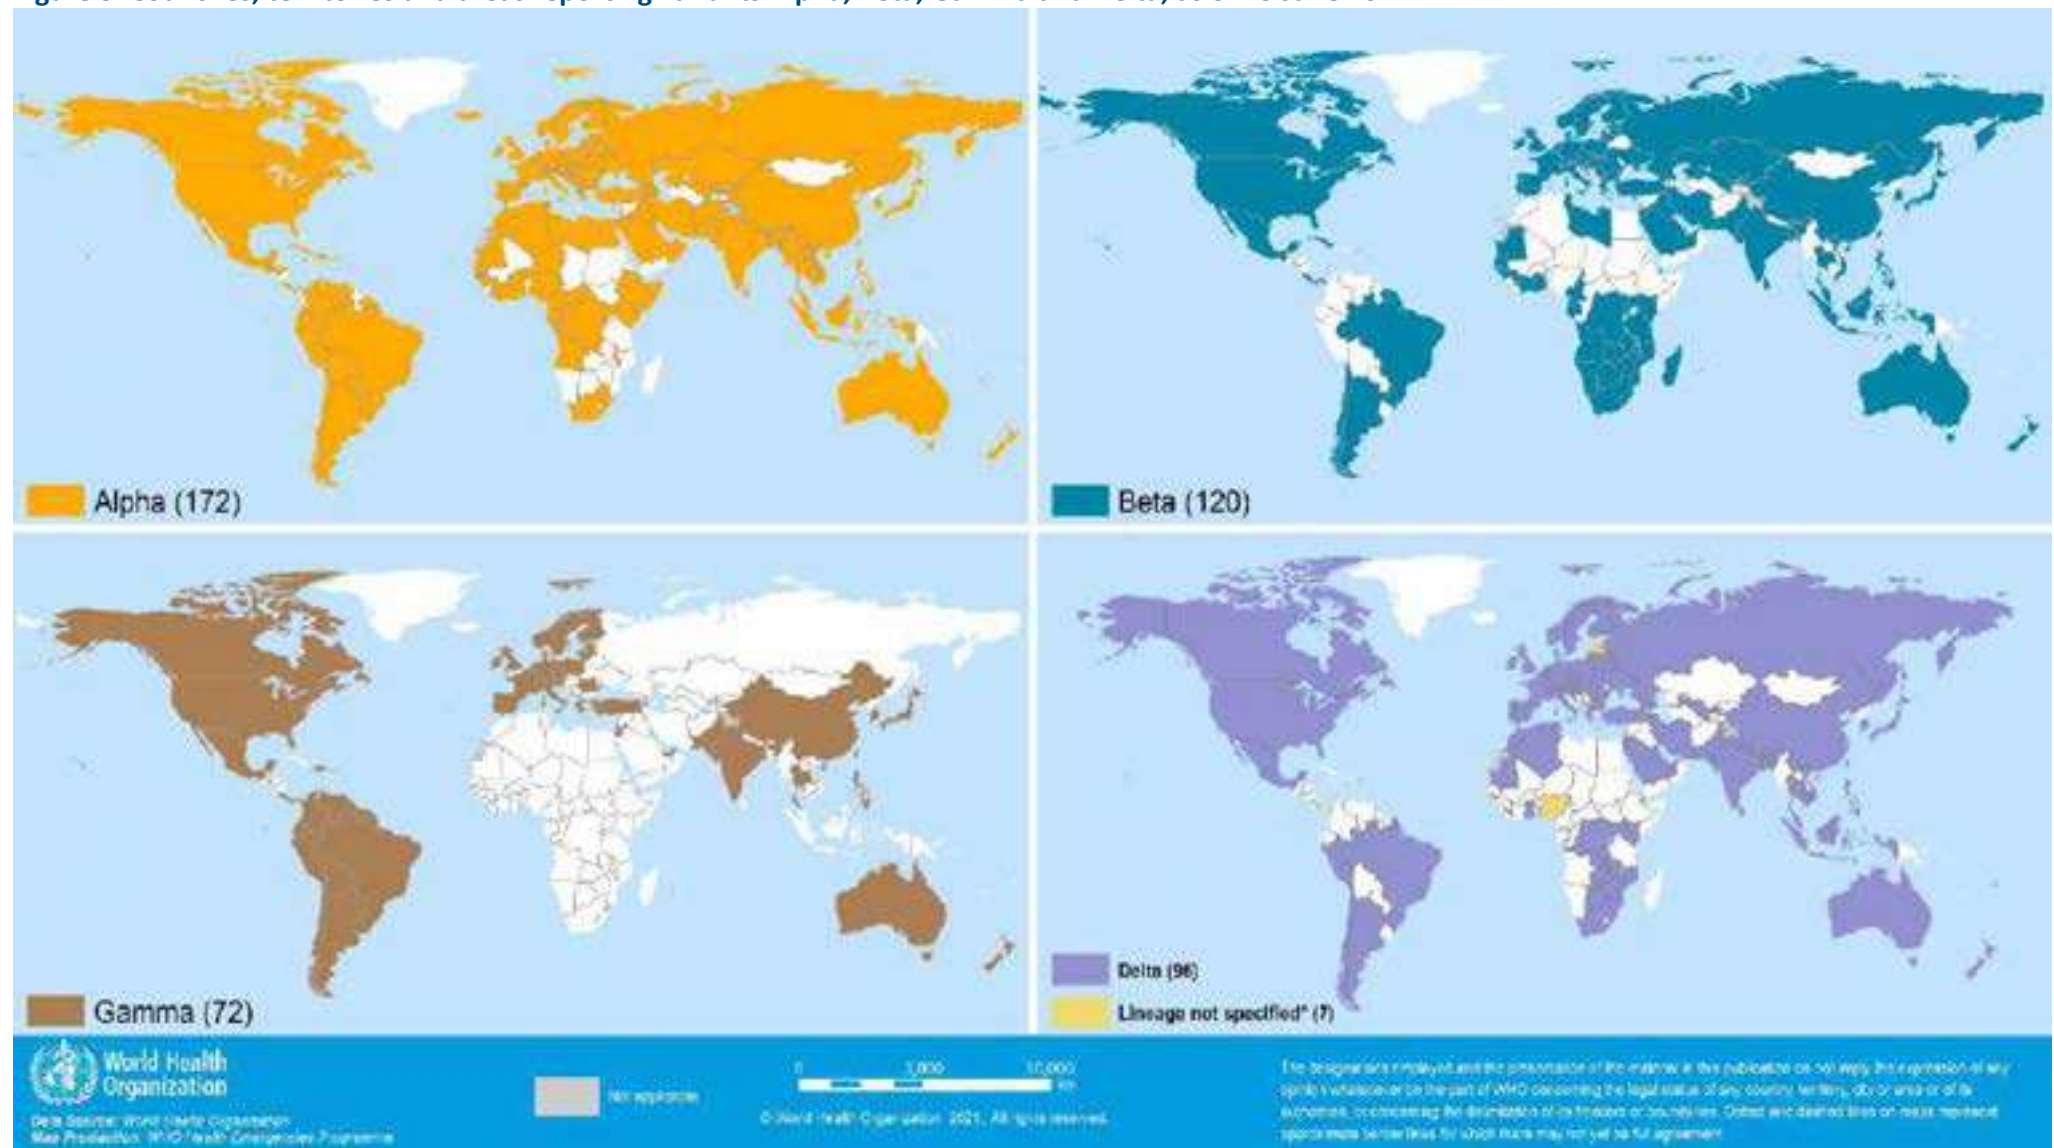

Virus evolution is expected, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations, are crucial aspects of the global strategy to reduce the occurrence of mutations that have

negative public health implications. PHSM remain critical to curb the spread of all SARS-CoV-2 variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that PHSM, including infection prevention and control (IPC) measures, have been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM and IPC measures. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual epidemiological events.

Figure 3. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 29 June 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

Special Focus: Current challenges in the context of the COVID-19 pandemic

Well into the second year of the COVID-19 pandemic, the global situation remains highly fragile. While at the global level, trends in cases and deaths have been declining in recent weeks, there is significant variation by region, by country and within countries. In all WHO regions, there are countries reporting sharp increases in cases and hospitalizations. There are a number of factors contribute to this, as repeatedly outlined by WHO,¹ including the emergence and circulation of more transmissible variants of SARS-CoV-2, increased social mixing and mobility, uneven and inequitable vaccination; and considerable pressure to lift public health and social measures.

SARS-CoV-2 variants of concern

On 11 May 2021, WHO designated Delta (B.1.617.2) as a variant of concern due to evidence of increased transmissibility.² The increase in the effective reproduction number compared with the Alpha variant (B.1.1.7) is estimated to be 55% (95% CI: 43–68).³ Given the increase in transmissibility, the Delta variant is expected to rapidly outcompete other variants and become the dominant variant over the coming months.³

As of 29 June 2021, 96 countries have reported cases of the Delta variant, though this is likely an underestimate as sequencing capacities needed to identify variants are limited. A number of these countries are attributing surges in infections and hospitalizations to this variant.

Low vaccination coverage at the global level

While more than 2.65 billion doses of COVID-19 vaccines have been administered,⁴ the majority of these have been in a small number of high-income countries. The gap in vaccine administration between high- and low-income countries is starting to shrink due to the delivery of vaccines through the COVAX facility, but the majority of the world's population still remains susceptible to SARS-CoV-2 infection and at risk of developing COVID-19.

Increased social mixing and lifting of public health and social measures

Countries have moved in and out of restrictions of varying stringency over the past 18 months. Now, many face considerable pressure to lift any remaining public health and social measures. Social mixing and mobility are increasing, as are the number of gatherings – from small-scale gatherings of friends and family to large sporting and side events, and religious celebrations. Improper planning or assessment of risk of transmission provide opportunities for the virus to spread.

WHO response

Since the beginning of the pandemic, WHO has recommended a comprehensive approach to controlling COVID-19,⁵ including the implementation and adjustment of public health and social measures to suppress transmission and reduce severe disease and death.⁶ This includes, but is not limited to, strong surveillance, strategic testing, early case detection, isolation and clinical care of cases by trained and protected health and care workers, tracing and supported quarantine of contacts, infection prevention and control measures, engineering controls and adopting risk-based approaches for gatherings and international travel. The

Available from: <https://www.who.int/publications/i/item/considerations-in-adjusting-public-health-and-social-measures-in-the-context-of-covid-19-interim-guidance>

addition of several safe and effective COVID-19 vaccines and the initiation of vaccination adds an incredibly powerful tool to complement prevention and control efforts.

Importantly, the tools that exist today—including individual-, community level-public health and social measures, infection prevention and control measures, that have been used since the beginning of the pandemic—remain effective against current variants of concern, including the Delta variant. Although the increased transmissibility of VOCs means that measures may need to be maintained for longer periods of time, particularly in a context of low vaccination coverage, these measures must be targeted, time-bound, reinforced and supported by Member States.

SARS-CoV-2 will continue to evolve, with selective advantage generally favouring more transmissible variants.⁷ The emergence of new variants requires constant evaluation and careful adjustment of public health and social measures and vaccination strategies as the COVID-19 pandemic continues.

WHO will continue to work with Member States and technical partners through existing and new technical networks and advisory groups to critically evaluate variants through the Global Risk Assessment and Monitoring Framework for SARS-CoV-2 variants.⁸ The situation is dynamic and WHO is working with partners to harmonize the decision-making processes for assessing the impact of variants of concern on public health and medical interventions.

Over the past 18 months, substantial progress has been made towards ending the acute phase of the COVID-19 pandemic. However, the combination of more transmissible variants, increasing social mixing, suboptimal vaccination coverage and relaxation of public health and social measures will slow this progress and delay the end of the pandemic.

Special focus: WHO global conference on communicating science during health emergencies, 7-25 June 2021

Copyright: WHO/Sam Bradd

Since the beginning of the pandemic, the evidence on COVID-19 and related protective measures evolved continuously. Changes in recommendations and pandemic response measures expose the public to high levels of uncertainty. Increasing pandemic fatigue and an overabundance of information highlight the need for effective, innovative and reliable science communication. Due to the all-disruptive nature of the COVID-19 pandemic, almost everybody has become a science communicator – be it at work, the dinner table or on social media.

However, scientific processes are complex and not always communicated in an understandable manner. To facilitate the solution-oriented discussion of challenges and innovations to improve the translation of science and make it accessible and relevant to all, the World Health Organization Information Network for Epidemics (WHO EPI-WIN) organized a global conference on communicating science during health emergencies from 7 to 25 June 2021. The conference took a multidisciplinary approach, convening science communicators, representing research, policy, civil society and international organizations, working in the areas of health, education, journalism and broadcasting, tourism and social media and culture, among others.

Conference structure

The [opening](#) and [closing](#) sessions of the [conference](#) featured renowned keynote speakers from academia and practice in the fields of public health, medicine, communication and design. Over 3000 participants from 159 countries joined the opening session and submitted almost 500 questions. To date, the recording of the opening session on YouTube has been viewed more than 14 000 times, reflecting the public interest in the topic of science communication during the pandemic. The closing session featured three innovative science communication concepts submitted to a global call for good practice examples launched by WHO in April 2021.

A panel further reported back on the thematic discussions held in June 2021 including researchers, media representatives, decision-makers and professionals working in health, education, tourism and culture. The thematic discussions included 61 experts from 26 countries. Discussions were grouped into four thematic tracks and ran over the course of three weeks. Each group attended three 90-minute discussions on profession-specific challenges and solutions to improve science communication during health emergencies. The discussions with the global experts disclosed some of the challenges science communicators have been facing

during the pandemic: from science being instrumentalized for political purposes, to a lack of scientific literacy among different population groups and a flood of information – both correct and incorrect - that does not take into account the target audiences' needs, beliefs and values.

Lessons learnt from the expert discussions

Participants identified key steps towards effective science translation. First, a need to re-think existing scientific processes to ensure research is being shared in a timely manner during health crises but still undergoes quality control and scientific debate. This includes a transparent communication of scientific processes to help people understand what science can and cannot do. While the public often expects science to provide clear answers, scientific knowledge generation takes time, is built on scientific debate and is inherently linked to uncertainty. Open communication of this uncertainty will prevent people from losing trust in science when the constantly evolving evidence leads to changes in public health recommendations. Second, the concerns, beliefs and needs of target audiences need to be taken into consideration when communicating science. There is no one-size-fits all solution. Instead of “pouring out” general information, a constant dialogue with communities is required to ensure the scientific information is relevant, understandable and credible to them. The continuous dialogue with different stakeholders will also help to build trust in science and encourage people to ask questions and voice concerns. Third, it takes innovation and creativity for effective science translation. People consume information on different channels, at different times of the day and in different formats. Science communication should add to people's lives in a meaningful and action-oriented manner and meet them where they are in terms of preferences, values and beliefs.

Next steps

WHO is committed to translating the insights from the conference into action; not just to improve science translation during the COVID-19 pandemic but also to be prepared for future health emergencies. Follow-up activities of the conference will include:

- Building a global, multidisciplinary network of science communicators. A continuous dialogue with researchers, media representatives, decision-makers and professionals working in health, education, culture and tourism will help to identify and address challenges in a concerted, collaborative manner;
- Developing capacity building resources for science communicators, especially journalists, to empower them to judge the quality and independence of scientific research and share this with their audiences;
- Strengthening scientific and health literacy in the whole population to empower all stakeholders to ask critical questions about the information they encounter on- and offline and make evidence-informed decisions;
- Analyzing existing good practice examples of science communication to understand what works and what does not work, and develop more effective, innovative science communication concepts for the future.

The high interest in the global conference confirmed WHO's mandate to play a key role in science communication during health emergencies. The timely implementation of follow-up activities will be crucial to support countries and the multidisciplinary science communication community to build trust in science and make it accessible and understandable to all.

WHO regional overviews - Epidemiological week 21-27 June 2021

African Region

Many countries in the African region continue to see increases in weekly case incidence and mortality. The Region reported over 177 000 new cases and over 2700 new deaths, a 34% and a 42% increase respectively compared to the previous week. The weekly number of COVID-19 cases has been increasing sharply since 15 May. Since then, 76% of cases and 72% of reported deaths in the Region were from countries in Southern Africa.

Aside from South Africa (103 697 new cases; 174.8 new cases per 100 000 population; a 47% increase), the highest numbers of new cases in the Region were reported from Zambia (19 058 new cases; 103.7 new cases per 100 000; a 15% increase), and Namibia (12 944 new cases; 509.4 new cases per 100 000; a 71% increase). Mortality in the African Region continued to increase sharply with the countries reporting the highest numbers of new deaths per 100 000 population over the past week being Namibia (11 new deaths per 100 000), Botswana (7 deaths per 100 000) and Zambia (20 new deaths per 100 000).

Updates from the [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.1 million new cases and over 30 000 new deaths, similar to the previous week. The Region reported the highest number of new cases and deaths per 100 000 over the past week when compared to the other regions (111 cases and 3 deaths per 100 000 population).

The highest numbers of new cases were reported from Brazil (521 298 new cases; 245.2 new cases per 100 000; a 3% increase), Colombia (204 132 new cases; 401.2 new cases per 100 000; a 5% increase), and Argentina (131 824 new cases; 291.7 new cases per 100 000; a 12% decrease).

The highest numbers of new deaths per 100 000 population were reported from Paraguay (113 deaths per 100 000), Colombia (90 deaths per 100 000) and Argentina (83 deaths per 100 000) over the past week.

Updates from the [Region of the Americas](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 221 000 new cases, a 13% increase compared to the previous week. This increase in cases is the largest relative increase seen in the Region since the end of March 2021. Over 3400 new deaths were reported, a similar number with the previous week. The Region reported 30 new cases and 0.5 new deaths per 100 000 population over the past week.

The highest numbers of new cases per 100 000 population were reported from Oman (348 new cases per 100 pop), Kuwait (294 new cases per 100 pop) and Tunisia (189 new cases per 100 000 pop).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (857 new deaths; 1.0 new deaths per 100 000; a 9% decrease), Tunisia (619 new deaths; 5.2 new deaths per 100 000; an 18% increase), and Afghanistan (528 new deaths; 1.4 new deaths per 100 000; an 11% decrease).

Updates from the [Eastern Mediterranean Region](#)

European Region

The European Region reported over 372 000 new cases, a 10% increase compared to the previous week, and over 6400 new deaths, similar to the previous week. This is the first weekly increase in the number of cases reported by the Region after more than two months of a decreasing trend.

The highest numbers of new cases were reported from the Russian Federation (134 465 new cases; 92.1 new cases per 100 000; a 24% increase), the United Kingdom (96 843 new cases; 142.7 new cases per 100 000; a 55% increase), and Turkey (38 936 new cases; 46.2 new cases per 100 000; a 2% decrease).

The highest numbers of new deaths were reported from the Russian Federation (3921 new deaths; 2.7 new deaths per 100 000; a 34% increase), Turkey (402 new deaths; 0.5 new deaths per 100 000; an 11% decrease), and Germany (369 new deaths; 0.4 new deaths per 100 000; a 33% decrease).

Updates from the [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 573 000 new cases and over 13 000 new deaths, a 5% and a 33% decrease respectively compared to the previous week. Although there is a slight overall decrease in the number of cases reported this week, mostly due to the decrease in the number of cases reported in India, a number of countries, including Myanmar (112% increase), Indonesia (60% increase) and Bangladesh (48% increase), reported large increases in the number of newly reported cases for this week.

The highest numbers of new cases were reported from India (351 218 new cases; 25.5 new cases per 100 000; a 21% decrease), Indonesia (125 395 new cases; 45.8 new cases per 100 000; a 60% increase), and Bangladesh (36 738 new cases; 22.3 new cases per 100 000; a 48% increase). The highest numbers of new deaths were reported from India (9038 new deaths; 0.7 new deaths per 100 000; a 45% decrease), Indonesia (2476 new deaths; 0.9 new deaths per 100 000; a 39% increase), and Bangladesh (624 new deaths; 0.4 new deaths per 100 000; a 45% increase).

Updates from the [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported over 116 000 new cases and over 1800 new deaths, a 6% and a 13% decrease respectively compared to the previous week. The weekly number of newly reported cases has decreased over the past several weeks, after reaching a peak in mid-May.

The highest numbers of new cases were reported from the Philippines (38 684 new cases; 35.3 new cases per 100 000; a 14% decrease), Malaysia (37 347 new cases; 115.4 new cases per 100 000; a 4% decrease), and Mongolia (16 111 new cases; 491.4 new cases per 100 000; a 7% decrease).

The highest numbers of new deaths were reported from the Philippines (706 new deaths; 0.6 new deaths per 100 000; a 20% decrease), Malaysia (536 new deaths; 1.7 new deaths per 100 000; a 6% increase), and Japan (257 new deaths; 0.2 new deaths per 100 000; a 30% decrease).

Updates from the [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the media briefing on COVID-19 – 25 June 2021](#), the Director-General highlighted one of the most important ways WHO coordinates the response to COVID-19 and other emergencies is through our global network of emergency medical teams. Globally, WHO has certified teams from 20 countries, who have gone through a rigorous process of quality assurance to ensure they meet internationally agreed standards.
- In [his introductory remarks at the high-level event: The Role of Primary Health Care in the COVID-19 Pandemic response and leading equitable recovery- 22 June 2021](#), the Director-General emphasized that there is no global health security without local health security, thus strengthening primary health care is essential for an equitable and resilient recovery.

Updates and publications

- [WHO support remains critical in countries and regions facing COVID-19 surges- 24 June 2021](#)
- [Directors General of WHO, WIPO and the WTO agree on intensified cooperation in support of access to medical technologies worldwide to tackle the COVID-19 pandemic – 24 June 2021](#)
- [Recommendations for national SARS-CoV-2 testing strategies and diagnostic capacities -25 June 2021](#)
- [Indicator framework for the evaluation of the public health effectiveness of digital proximity tracing solutions- 25 June 2021](#)

Annex

COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region (reported in previous issues) are now available at: <https://covid19.who.int/table>

*Newly reported in this update.

Unspecified B.1.617 reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

on for this variant was received by WHO from official sources.

ation become available.

**Variant Delta for Honduras, Iraq, Kazakhstan, Kyrgyzstan and Oman were excluded this week based on further information received.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Efforts are ongoing to differentiate these in future reports. Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Global overview

Data as of 20 June 2021

Global numbers of cases and deaths continued to decrease over the past week (14-20 June 2021) with over 2.5 million new weekly cases and over 64 000 deaths, a 6% and a 12% decrease respectively, compared to the previous week (Figure 1). While the number of cases reported globally now exceeds 177 million, last week saw the lowest weekly case incidence since February 2021. This week, the Americas and Western Pacific Regions reported numbers of new weekly cases similar to the previous week, while the South-East Asia and the European Regions reported a decline in the number of new cases. The African Region recorded a marked increase in the number of weekly cases as compared to the previous week (Table 1). Globally, mortality remains high with more than 9000 deaths reported each day over the past week, however, the number of new deaths reported in the past week decreased across all Regions except for the Eastern Mediterranean and the African Regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 20 June 2021**

**See [Annex 2: Data, table and figure notes](#)

The highest numbers of new cases were reported from Brazil (505 344 new cases; 11% increase), India (441 976 new cases; 30% decrease), Colombia (193 907 new cases; 10% increase), Argentina (149 673 new cases; 16% decrease), and the Russian Federation (108 139 new cases; 31% increase).

Globally, variant Alpha has been reported in 170 countries, territories or areas (hereafter countries; seven new countries in the past week), Beta in 119 countries (four new countries), Gamma in 71 countries (three new countries) and Delta in 85 countries (six new countries).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 20 June 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 143 672 (45%)	0%	70 663 034 (40%)	30 748 (48%)	-4%	1 857 523 (48%)

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact vaccine, therapeutics, diagnostics or public health and social measures (PHSM) applied by national authorities to control disease spread. Systems have been established to detect signals of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) and assess these based on the risk posed to global public health. As these risks evolve, WHO updates the list of global VOIs and VOCs (Table 2) to support setting priorities for surveillance and research, and ultimately guide response strategies. National authorities may choose to designate other variants of local interest/concern, and are encouraged to investigate and report on the impact of these variants. Here we provide updates on globally characterized VOCs and VOIs, as well as the updated countries/territories/areas reporting the detection of VOCs. No new VOCs or VOIs have been added to or removed from the list last week.

Table 2: SARS-CoV-2 Variants of Concern (VOCs) and Variants of Interest (VOIs), as of 22 June 2021

WHO label	Pango lineage	GISAID clade	Nextstrain clade	Earliest documented samples	Date of designation
Variants of Concern (VOCs):					
Alpha	B.1.1.7	GRY (formerly GR/501Y.V1)	20I (V1)	United Kingdom, Sep-2020	18-Dec-2020

*Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs and vaccine performance against VOCs are summarised in Table 3, as well as in [previous editions](#) of the WEU.

Since the last detailed [update](#) on 8 June, new evidence has been published on the phenotypic characteristics of the Delta variant. A study from Singapore showed that infection with Delta variant was associated with higher odds of oxygen requirement, intensive care unit (ICU) admission, or death [adjusted odds ratio (aOR) 4.90, 95% CI 1.43-30.78]. Additionally, the aOR for pneumonia was 1.88 times higher (95% CI 0.95-3.76) for those infected with Delta compared to infection with non-VOC SARS-CoV-2 lineages. Additionally, the Delta variant was associated with significantly lower PCR cycle threshold (Ct) values - the lower the Ct level the greater the amount of viral RNA in a sample. Findings from this study also showed that there was a longer duration of sustained low Ct values (≤ 30) in Delta (median duration of 18 days) compared to non-VOC lineages of SARS-CoV-2 (13 days).⁸⁷

A study in Japan estimating the relative instantaneous reproductive number (a measure of transmission at a specific point in time) showed that the Delta variant was associated with greater transmissibility when compared to the Alpha variant. When compared with the variants circulating in Japan before December 2020, the relative instantaneous reproduction number for Alpha was estimated to be at 1.56 and for Delta 1.78. Overall, this study showed Delta was associated with 1.23 times higher transmissibility than Alpha.⁸⁸ This is consistent with the summary of Rt of Alpha, Beta, Gamma and Delta variants published by WHO in previous issues of the [Weekly Epidemiological Update on COVID-19](#) and in Eurosurveillance this past week⁸⁹.

Findings from a recently published retrospective cohort analysis involving nearly 840 000 participants with laboratory confirmed SARS-CoV-2 in England between 23 November 2020 and 31 January 2021 suggested that the Alpha variant, as compared to non-VOC SARS CoV-2 lineages, was associated with an increased risk of hospitalization between one and fourteen days after the first positive SARS-CoV-2 test (adjusted hazard ratio of hospital admission 1.52, 95% CI 1.47 - 1.57). When looking at these results by age, they showed a higher risk of hospitalization among those aged ≥ 30 years as compared to younger participants.⁹⁰ Another study comparing the secondary attack rates in households among Alpha index cases versus non-VOC index cases in Ontario, Canada found that the secondary attack rate for Alpha index cases was 1.31 times (31%) higher than non-VOC index cases (RR=1.31, 95%CI 1.14-1.49). When these analyses were further grouped into Alpha and non-Alpha index cases, there was evidence to suggest increased transmission among both asymptomatic (RR=1.91, 95% CI 0.96-3.80) and pre-symptomatic (RR=3.41, 95%CI 1.13-10.26) index cases.¹

A study conducted to examine diagnostic accuracy of three SARS-CoV-2 antigen detecting rapid tests (Ag-RDT) in Germany between 20 January to 15 April 2021 showed comparable sensitivities in the performance of Ag-RDTs for Alpha, Beta and wild-type variants, irrespective of the infecting variant.⁹¹ This finding is consistent with a previously published evaluation by Public Health England which found no major changes in the diagnostic accuracy of six widely available Ag-RDTs for Alpha, despite a limited number of amino acid changes from the original viral sequence in the target antigen for most commercially available Ag-RDTs.²²

A recent study using a transmission model based on clinical and epidemiological data from almost 1000 individuals from South Africa and Switzerland, estimated that the Alpha variant was associated with either

a 37% (95% compatibility interval, CI: 25–63%) increase in transmissibility or a 51% (95% CI: 32-80%) increase of the infectious duration or a combination of the two mechanisms. It was also estimated that the Beta variant was associated with a 23% (95% CI: 10-37%) increase in transmissibility or a 38% (95% CI: 15-78%) increase of the infectious duration. The authors concluded that Beta might be expected to outgrow Alpha in regions where the level of naturally acquired immunity against previously circulating variants exceeds 20% to 40%.⁹² The study also measured viral load in 950 individuals and found that infections with variant Alpha exhibited a higher viral load and longer viral shedding compared to non-VOCs. Findings from another study showed that the receptor binding domain (RBD) of the Alpha and Beta variants bound ACE2 with 1.98- and 4.62 times greater affinity than non-VOCs, respectively. This enhanced affinity likely mediates increased infectivity by lowering the effective concentration of virions required for cell entry.⁹³

In a rapid scoping review examining the impacts of VOCs on health systems, authors of a recently published study suggested that a combination of public health and social measures (e.g., masking, physical distancing, lockdowns, testing) should be implemented alongside a vaccine strategy to improve population and health system outcomes.⁹⁴

VOC impacts on vaccines

Since the 8 June [update](#), two studies have provided evidence of the effectiveness of Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines against the Delta variant. The first is a follow-up to a United Kingdom study published last month by Lopez Bernal et al., which reported on vaccine effectiveness (VE) of full courses of both Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines against symptomatic disease due to the Delta variant; VE against Delta, while slightly reduced, was maintained for both vaccines (88% for Pfizer BioNTech-Comirnaty and 67% for AstraZeneca-Vaxzevria).⁴¹ In the follow-up study, Stowe et al. report on the effectiveness of these vaccines against severe disease (hospitalization) due to Delta among persons ≥ 16 years in the United Kingdom. The authors combined odds ratios for symptomatic COVID-19 disease from a test-negative case-control analysis with hazard ratios for hospitalization among symptomatic cases to estimate overall VE against hospitalization. VE estimates against hospitalization due to Delta and Alpha variants ≥ 14 days post second dose was estimated to be 96% (95% CI: 86-89%) and 95% (95% CI: 78-99%) respectively, for Pfizer BioNTech-Comirnaty and 92% (85% CI: 75-97%) and 86% (95% CI: 53-96%) respectively, for AstraZeneca-Vaxzevria. Single dose effectiveness against hospitalization ≥ 21 days after immunization remained high for Pfizer BioNTech-Comirnaty at 94% (95% CI: 46-99%) against Delta and 83% (95% CI: 62-93%) against Alpha. Effectiveness of one dose of AstraZeneca-Vaxzevria against hospitalization was similar for Delta and Alpha variants, but reduced relative to two doses at 71% (95% CI: 51-83%) and 76% (95% CI: 61-85%), respectively.⁴⁰

A second study from Scotland by Sheikh et al. applied a test negative case-control design to a large COVID-19 surveillance platform and found that two doses of Pfizer BioNTech-Comirnaty were 83% (95% CI: 78-87) and 79% (95% CI: 75-82%) effective against symptomatic disease and infection due to Delta, respectively, ≥ 14 days after receipt of second dose in persons 15 years and older. These estimates were somewhat reduced compared to VE estimates against Alpha: 92% (95% CI: 88-94%) and 92% (90-93%) for symptomatic disease and infection, respectively. The study also showed reduced effectiveness of two doses of AstraZeneca-Vaxzevria against Delta compared to Alpha with VE estimates of 61% (95% CI: 51-70%) and 60% (95% CI: 53-66%) against symptomatic disease and infection ≥ 14 days after second dose,

respectively, compared to corresponding estimates of 81% (95% CI: 72-87%) and 73% (95% CI: 66-78%) against Alpha. Single dose effectiveness against Delta was similar to that of Alpha with low VE for both vaccines and for both symptomatic disease and infection ≥ 28 days after immunization with VE estimates ranging from 18% to 39%. In a separate cohort analysis, single dose effectiveness against hospitalization ≥ 28 days after immunization among SARS-CoV-2 positive individuals was estimated for Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines combined; VE was estimated to be 62% (95% CI: 42-76%) and 72% (95% CI: 57-82%) against Delta and Alpha, respectively, demonstrating lower protection against Delta compared to Alpha (though confidence intervals overlap, indicating no statistical significance).⁴²

Together, these studies suggest moderately reduced VE at preventing symptomatic disease and infection due to the Delta variant as compared to Alpha. While the Scotland study suggests there could be reduced effectiveness of vaccines against hospitalization due to Delta as compared to Alpha, confidence levels overlap and VE for individual vaccines was not estimated. No such reduction in VE was observed for hospitalization in the United Kingdom study for either Pfizer BioNTech-Comirnaty or AstraZeneca-Vaxzevria vaccines. The studies also provide further evidence of the importance of two doses of both Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria in preventing hospitalization, symptomatic disease and infection due to both Delta and Alpha variants.

A third study by Skowronski et al. evaluated the effectiveness of a single dose of Pfizer BioNTech-Comirnaty or Moderna-mRNA-1273 against infection with SARS-CoV-2 Alpha and Gamma variants among older adults in Canada using a test-negative case-control design; 85% of participants had received Pfizer BioNTech-Comirnaty and 15% had received Moderna-mRNA-1273 vaccine. VE against Alpha and Gamma variants ≥ 21 days after the first dose were 67% (95% CI: 57-75%) and 61% (95% CI: 45-72%), respectively, compared to 72% (95% CI: 58-81) against non-VOC SARS-CoV-2 viruses.³⁹ While the VE point estimate against Gamma was somewhat lower compared to Alpha and non-VOCs, all confidence intervals were overlapping, indicating no statistical significance.

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing and sharing of sequences and supporting meta-data, the number of countries/areas/territories (hereafter countries) reporting VOCs has continued to increase (Figure 4, Annex 1). In the past two weeks, Alpha continued to be reported in new countries, including smaller island nations in the Americas and Southeast Asia Regions. Delta, now reported in 85 countries globally, continues to be reported in new countries across all WHO Regions, 11 of which were newly reported in the past two weeks. This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

WHO recommendations

Virus evolution continues to be expected, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations, are fundamental to and crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2, including all variants that evolve.

Evidence from multiple countries with extensive transmission of VOCs has indicated that PHSM, including infection prevention and control (IPC) measures in health facilities, have been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

Figure 4. Countries, territories and areas reporting variants Alpha, Beta, Gamma and Delta, as of 22 June 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

Special focus: Global Consultation on SARS-CoV-2 Variants of Concern and their Impact on Public Health Interventions

On 10 June 2021, WHO convened a second Global Consultation on SARS-CoV-2 Variants of Concern (VOCs) and their Impact on Public Health Interventions, as part of its efforts to coordinate the global response to SARS-CoV-2. Global stakeholders came together to present the existing evidence on VOCs, review information needs and decision-making processes, and outline potential decision-making processes for modifying COVID-19 vaccine composition.

According to experts, continued SARS-CoV-2 evolution is expected and requires strengthening epidemiological and genomic surveillance. In response, the WHO SARS-CoV-2 Virus Evolution Working Group (VEWG), which is in the process of being formalized as the Technical Advisory Group on SARS-CoV-2 Virus Evolution (TAG-VE), was established to monitor new mutations and variants, assess their potential public health impact, and rapidly identify and coordinate the filling of research gaps related to transmissibility, severity and neutralization of specific mutations and variants. Available evidence on variants are shared, discussed and used to characterize as VOCs or Variants of Interest (VOIs) by WHO in consultation with this group. The four current VOCs being monitored closely – Alpha, Beta, Gamma and Delta - are widespread (Table 2) and have been detection in all WHO regions. The Delta variant is significantly more transmissible than Alpha variant, and is expected to become a dominant lineage if current trends continue.⁸⁹

In addition to increased transmissibility, SARS-CoV-2 evolution may result in changes that allow for increased disease severity, escape from immune responses, decreased effectiveness of antiviral treatment or infection in a new animal host. While current VOCs show antigenic distance from vaccine immunogens (the part of the virus gene that the vaccines targets), the current vaccines are still effective at protecting against severe disease and hospitalization. Experience from multiple countries with extensive transmission of the four VOCs has demonstrated that proven public health and social measures (PHSM), including infection prevention and control (IPC) measures in health facilities, remain effective in controlling VOCs and VOIs.

As several vaccines are in use and under development, coordinated decision-making on vaccine modification and administration is required. A newly-formed Technical Advisory Group on vaccine composition (TAG-CO-VAC) will review available evidence and provide recommendations on vaccine modifications if needed; specific considerations include appropriate antigen selection for broad protection, using broadly protective variant-specific vaccines in non-immune individuals, and balanced timing of booster vaccinations to ensure continued efficacy while avoiding extra vaccination if previous vaccination is still protective. Preliminary results from an ongoing systematic review of randomized studies suggest that current COVID-19 vaccines provide moderate protection against current VOCs, though the results should be interpreted with caution due to low-powered analyses with incomplete data. Pre-clinical and clinical assessments suggest that protection against SARS-CoV-2 variants can be expected among the diverse array of vaccines both currently available and in development. Moving forward, evidence for vaccine modification decision-making should include stronger epidemiological and genomic surveillance data, especially from low- and middle-income countries, information on breakthrough infections (infections of individuals who have been fully vaccinated for ≥ 14 days), and a better understanding of protective immunity at the individual and population levels in the context of circulating variants. Importantly, a clearing house documenting the most current evidence on variants would enable informed decision-making.

From the perspective of vaccine regulators and 11 vaccine developers that shared their plans during the consultation, there is ongoing work to assess the need to boost current vaccines. If/when this becomes necessary, it will be important that the regulatory community continues to work collaboratively. Moreover, whichever strategy is used (a booster dose of prototype vaccines or a variant-specific vaccine), should induce broad protection. Given the differential prevalence of variants, vaccine availability and vaccination rates, implementation of a 'mix and match' vaccination approach may be necessary. Country and global-level decision-makers echoed the call for better integrated genomic and epidemiological surveillance, including at the sub-national level, and the human resources to carry out the collection and rapid sharing of data and

analyses on variants. More complete evidence on variants and their impact on public health interventions is required for evidence-based recommendations, which could include modelling-based analyses. Additionally, the rapid sharing of data will support vaccine developers to develop new variant vaccines, if this becomes necessary.

In summary, this consultation provided a global forum to share the latest information and evidence regarding SARS-CoV-2 variants and their impact on public health interventions. The key messages from this consultation are:

- The public health interventions in place for COVID-19, including public health and social measures and vaccines, are still effective against the current VOCs (Alpha, Beta, Gamma and Delta variants);
- Variants will continue to emerge over time, and this is expected. While not all will be of concern, continuous monitoring and assessment is necessary. WHO's TAG-VE will continue to advise WHO on the characterization of VOIs and VOCs. Because more variants will likely emerge, there is also a critical need to continue assessing the available evidence on impacts on therapeutics, diagnostics and the impact on current and future COVID-19 vaccines. WHO is establishing the TAG-CO-VAC to interpret available evidence and provide recommendations for adapting COVID-19 vaccine composition, if needed;
- WHO remains committed to coordinating the response against SARS-CoV-2 variants by supporting its Member States and collaborating with stakeholders.

The recording from the consultation can be found [here](#) (passcode: m#t9b!TI).

WHO regional overviews - Epidemiological week 14-20 June 2021

African Region

The African Region reported over 132 000 new cases and over 1900 new deaths, a 39% and a 38% increase respectively compared to the previous week, the highest percentage increase reported globally. The region reported a marked increase in weekly case incidence for the past month, with the largest increases in countries in the Southern and Eastern parts of Africa. The highest numbers of new cases were reported from South Africa (70 739 new cases; 119.3 new cases per 100 000 population; a 48% increase), Zambia (16 641 new cases; 90.5 new cases per 100 000; a 54% increase), and Uganda (9926 new cases; 21.7 new cases per 100 000; a 16% increase).

The highest numbers of new deaths were reported from South Africa (937 new deaths; 1.6 new deaths per 100 000 population; a 29% increase), Zambia (230 new deaths; 1.3 new deaths per 100 000; a 271% increase), and Uganda (203 new deaths; 0.4 new deaths per 100 000; a 314% increase).

Updates from [African Region](#)

Region of the Americas

The Region of the Americas reported over 1.1 million new cases and over 30 000 new deaths, a similar number of cases and a 4% decrease in deaths compared to the previous week. Despite this, high levels of transmission and mortality are still being recorded in many countries in South and Central America as well as in the Caribbean. The highest numbers of new cases were reported from Brazil (505 344 new cases; 237.7 new cases per 100 000; an 11% increase), Colombia (193 907 new cases; 381.1 new cases per 100 000; a 10% increase), and Argentina (149 673 new cases; 331.2 new cases per 100 000; a 16% decrease).

The highest numbers of new deaths were reported from Brazil (14 264 new deaths; 6.7 new deaths per 100 000; a 7% increase), Colombia (4131 new deaths; 8.1 new deaths per 100 000; an 11% increase), and Argentina (3619 new deaths; 8.0 new deaths per 100 000; a 14% decrease).

Updates from [Region of the Americas](#)

Eastern Mediterranean Region

Following two months of decline in the weekly case incidence, the Eastern Mediterranean Region reported over 195 000 new cases and over 3400 new deaths, similar numbers as compared to the previous week. Nearly half of countries across the region are starting to report increasing case and death incidence, including Afghanistan, Kuwait, Somalia and Syrian Arab Republic. The highest numbers of new cases were reported from the Islamic Republic of Iran (66 452 new cases; 79.1 new cases per 100 000; an 11% increase), Iraq (32 614 new cases; 81.1 new cases per 100 000; a 12% increase), and the United Arab Emirates (14 162 new cases; 143.2 new cases per 100 000; a 4% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (943 new deaths; 1.1 new deaths per 100 000; a 3% decrease), Afghanistan (595 new deaths; 1.5 new deaths per 100 000; a 56% increase), and Tunisia (524 new deaths; 4.4 new deaths per 100 000; a 7% increase).

Updates from [Eastern Mediterranean Region](#)

European Region

The European Region reported over 324 000 new cases and over 6400 new deaths, a 6% and a 12% decrease respectively compared to the previous week. While most countries across the Region continue to see decreasing or stabilizing trends, some countries, including Greenland, Israel, Kyrgyzstan, Portugal, the Russian Federation and Slovakia have reported increases in the number of cases and deaths this week compared to the previous week. The highest numbers of new cases were reported from the Russian Federation (108 139 new cases; 74.1 new cases per 100 000; a 31% increase), the United Kingdom (62 474 new cases; 92.0 new cases per 100 000; a 33% increase), and Turkey (39 773 new cases; 47.2 new cases per 100 000; a 7% decrease).

The highest numbers of new deaths were reported from Russian Federation (2931 new deaths; 2.0 new deaths per 100 000; an 11% increase), Germany (551 new deaths; 0.7 new deaths per 100 000; a 10% decrease), and Turkey (454 new deaths; 0.5 new deaths per 100 000; a 24% decrease).

Updates from [European Region](#)

South-East Asia Region

The South-East Asia Region reported over 600 000 new cases and over 19 000 new deaths, a 21% and a 26% decrease respectively compared to the previous week. Decreasing trends in weekly case and death incidence in the Region are predominantly associated with decreases reported in India. Other countries, including Myanmar, Bangladesh and Indonesia, reported increasing case and death incidence this week when compared to the previous week.

The highest numbers of new cases were reported from India (441 976 new cases; 32.0 new cases per 100 000; a 30% decrease), Indonesia (78 551 new cases; 28.7 new cases per 100 000; a 42% increase), and Bangladesh (24 746 new cases; 15.0 new cases per 100 000; a 55% increase).

The highest numbers of new deaths were reported from India (16 329 new deaths; 1.2 new deaths per 100 000; a 31% decrease), Indonesia (1783 new deaths; 0.7 new deaths per 100 000; a 41% increase), and Bangladesh (430 new deaths; 0.3 new deaths per 100 000; a 54% increase).

Updates from [South-East Asia Region](#)

Western Pacific Region

The Western Pacific Region reported just under 124 000 new cases, a similar number to the previous week, and just over 2000 new deaths, a 9% increase compared to the previous week. While the Region reported a decreasing trend in the last couple of weeks, some countries, including Fiji, Mongolia and Singapore recorded increases in the numbers of cases this week compared to the previous week.

The highest numbers of new cases were reported from the Philippines (44 875 new cases; 41.0 new cases per 100 000; a 3% decrease), Malaysia (38 911 new cases; 120.2 new cases per 100 000; a 7% decrease), and Mongolia (17 255 new cases; 526.3 new cases per 100 000; a 74% increase).

The highest numbers of new deaths were reported from the Philippines (886 new deaths; 0.8 new deaths per 100 000; a 4% decrease), Malaysia (504 new deaths; 1.6 new deaths per 100 000; a 9% decrease), and Japan (367 new deaths; 0.3 new deaths per 100 000; a 28% decrease).

Updates from [Western Pacific Region](#)

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the media briefing on COVID-19 – 21 June 2021](#), the Director-General highlighted how the COVID-19 pandemic has shown that relying on a few companies to supply global public goods is limiting, and dangerous. To boost manufacturing, WHO has continued to call for the sharing of know-how, technology and licenses, and the waiving of intellectual property rights.
- He announced that WHO is in discussions with a consortium of companies and institutions to establish a [technology transfer hub in South Africa for COVID-19 mRNA vaccines](#). Tech-transfer hubs are training facilities where manufacturers from low- and lower-middle income countries can receive training in how to produce certain vaccines, and the relevant licenses to do so.
- In his [opening remarks at World Local Production Forum: Enhancing access to medicines and other health technologies - 21 June 2021](#), the Director-General emphasized that WHO is fully committed to supporting a landmark resolution, which was adopted by the World Health Assembly just a few weeks ago and co-sponsored by over 100 countries, on strengthening local production of medicines and other health technologies to improve access – specifically to strengthen production capacity where it exists, and to build it where it is lacking.

*Newly reported in this update.

reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.
WHO from official sources.

ation become available.

**Variant Alpha for Comoros and Delta for Afghanistan were excluded this week based on further information received.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Efforts are ongoing to differentiate these in future reports. Excludes countries, territories, and areas that have never reported the detection of a variant of concern.

See also [Annex 2: Data, table and figure notes](#).

Annex 2. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

COVID-19 Weekly Epidemiological Update

Edition 44, published 15 June 2021

In this edition:

- [Global overview](#)
- [Special focus: Strengthening public health intelligence through event-based surveillance – learning from the COVID-19 pandemic](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 13 June 2021

Global numbers of cases and deaths continued to decrease over the past week (7-13 June 2021) with over 2.6 million new weekly cases and over 72 000 deaths, a 12% and a 2% decrease respectively, compared to the previous week (Figure 1). While the number of cases reported globally now exceeds 175 million, last week saw the lowest weekly case incidence since February 2021. Declines in the number of new weekly cases were reported across all Regions except for the African Region. The South-East Asia, European and Western Pacific Regions reported marked declines in the number of new cases in the past week, whereas the Region of the Americas and the Eastern Mediterranean Region reported similar numbers as compared to the previous week (Table 1). While the number of new deaths reported in the past week decreased across all Regions except for the African and the South-East Asia Regions, globally mortality remains high with more than 10 000 deaths reported each day. While the epidemics in some of the most affected countries have started to show signs of slowing down, and the global weekly mortality rate continues to decline for a sixth consecutive week, many countries across all WHO Regions continue to struggle with access to vaccines, the spread of emerging SARS-CoV-2 variants, and overburdened healthcare systems.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 13 June 2021**

**See Annex 3: Data, table and figure notes

The highest numbers of new cases were reported from India (630 650 new cases; 31% decrease), Brazil (454 710 new cases; similar to the previous week), Argentina (177 693 new cases; 17% decrease), Colombia (176 661 new cases; similar to the previous week) and the United States of America (105 019 new cases; 6% increase).

Special focus: Strengthening public health intelligence through event-based surveillance – learning from the COVID-19 pandemic

Public health intelligence and event-based surveillance

Public health intelligence (PHI) is a conceptual framework that encompasses all activities that relate to the detection, verification, assessment, investigation and communication of information on events that pose a potential risk to human health (e.g., disease, natural disaster, chemical exposure). PHI serves as an early warning and response system, which is informed by indicator-based surveillance (IBS), which uses structured data from formal sources, and [event-based surveillance \(EBS\)](#) which uses informal sources such as media articles, hotlines and community reports, in order to detect acute public health events and/or risks.

EBS aims to rapidly collect, monitor, assess and interpret information in an organized manner and complement information derived from IBS. EBS involves the detection, triaging (filtering and selection) and verification of new public health threats as well as relevant changes in ongoing events. It also triggers risk assessments that may consequently lead to a response (Figure 3). Successful EBS depends on efficient networks, timely information sharing, diverse sources, collaboration and buy-in of stakeholders. A signal is information that is collected and triaged as a potential public health risk and can include changes in an ongoing event. Signals are rapidly detected from media and community sources to complement IBS data, demonstrating the importance of systematic integration of EBS in PHI. EBS can more readily be established in limited-resource settings compared to IBS, where surveillance structures may be limited or absent.

Figure 3. Processes and information flow for public health intelligence

Modified from [Early detection, assessment and response to acute public health events: Implementation of Early Warning and Response with a focus on Event-Based Surveillance Epidemic Intelligence process](#).

EBS informs the COVID-19 response

In the context of COVID-19, EBS has informed WHO's COVID-19 response by providing important contextualization of epidemiological data in a timely manner. Media monitoring in multiple languages has been the main method for EBS. Signals of interest from around the world are identified, assessed and documented daily based on predefined criteria. These criteria consider changes in epidemiology, virus mutations/variants, testing, impact on vulnerable populations, clusters related to various settings (e.g., workplaces, schools,

prisons and long-term care homes), as well as the implementation of public health and social measures (PHSM), changes in travel patterns and restrictions, social gatherings and events. Criteria are adapted over time depending on emerging knowledge and are tailored to specific needs at global and regional levels. EBS is also used to identify potential areas of concern, by monitoring reports of health system capacity, and to inform estimates of disease dynamics in areas where surveillance or reporting are limited.

The [Epidemic Intelligence from Open Sources \(EIOS\)](#) system is one of the main tools used by WHO to conduct monitoring of publicly available information, including for COVID-19. It is a fit-for-purpose but constantly evolving web-based system designed to augment and accelerate global public health intelligence activities. The core of the EIOS system is developed by the Joint Research Centre of the European Commission based on a long-standing collaboration with WHO. The EIOS system is the technological centerpiece of the broader EIOS initiative, a unique collaboration between various public health stakeholders around the globe. EIOS brings together new and existing initiatives, networks and systems to create a unified all-hazards, One Health approach to early detection, verification, assessment and communication of public health threats using publicly available information.

Evolution of COVID-19 EBS

Since the beginning of the COVID-19 pandemic, the scope and processes for EBS has evolved to reflect the changing response priorities. Early in 2020, during the early weeks and months of the pandemic, EBS media monitoring complemented official reporting of case and death counts through the [International Health Regulations \(IHR 2005\)](#) mechanism. As the pandemic evolved, EBS more regularly identified epidemiological trends in COVID-19 disease patterns, sometimes unusual, that were not readily captured by global indicator-based surveillance. Topics of interest have also evolved over time, such as health systems capacity, the introduction of vaccines, emergence of new variants, unusual clinical presentations and manifestations as well as upsurges in case and deaths in localized areas and among population groups at risk; for example, health care workers, rapid response teams, indigenous populations, children, pregnant women and the elderly.

Consistent and systematic media monitoring, however, has been challenging due to the unprecedentedly high volume of reports and media articles, and the rapid evolution of risks and response needs. In response to these challenges, WHO strengthened the collaboration across all regions throughout 2020 through the shared use of the EIOS system to maximize the use of resources and to jointly address challenges. This collaboration has facilitated information sharing and increased efficiency of work, particularly around detection and assessment of SARS-CoV-2 variants and supported a rapid response.

The COVID-19 pandemic has highlighted an opportunity for new and strengthened collaborations among WHO, Member States and partners, as well as strengthened communication between WHO offices. EBS has provided critical public health intelligence during the COVID-19 pandemic and can continue adapting to align with evolving needs of this pandemic. Sustained, multi-level collaboration is needed to enable continuous adaptation to the changing surveillance landscape and to further improve geographical representativeness of EBS sources. Best practices and lessons learned in EBS during the COVID-19 pandemic can also be applied to strengthen and optimize non-COVID-19 surveillance.

Special Focus: Update on SARS-CoV-2 Variants of Interest and Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, routinely assess if variants of SARS-CoV-2 alter transmission or disease characteristics, or impact effectiveness of vaccines, therapeutics, diagnostics, or public health and social measures (PHSM) applied by national authorities to control disease spread. Systems have been established to detect “signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) and assess these based on the risk posed to global public health. As these risks evolve, WHO will update lists of global VOIs and VOCs (Table 2) to support setting priorities for surveillance and research, and ultimately guide response strategies.

National authorities may choose to designate other variants of local interest/concern and are encouraged to investigate and report on impacts of these variants. Here we provide updates on classifications of VOCs and VOIs, including a newly designated global VOI – Lambda (lineage C.37) – as well as the updated countries/territories/areas reporting the detection of VOCs.

Table 2: SARS-CoV-2 Variants of Concern (VOCs) and Variants of Interest (VOIs), as of 15 June 2021

WHO label	Pango lineage	GISAID clade	Nextstrain clade	Earliest documented samples	Date of designation
Variants of Concern (VOCs):					
Alpha	B.1.1.7	GR/501Y.V1 (formerly GR/501Y.V1)	20I (V1)	United Kingdom, Sep-2020	18-Dec-2020
Beta	B.1.351	GH/501Y.V2	20H (V2)	South Africa, May-2020	18-Dec-2020
Gamma	P.1	GR/501Y.V3	20J (V3)	Brazil, Nov-2020	11-Jan-2021
Delta	B.1.617.2	G/478K.V1	21A	India, Oct-2020	VOI: 4-Apr-2021 VOC: 11-May-2021
Variants of Interest (VOIs):					
Epsilon	B.1.427/ B.1.429	GH/452R.V1	21C	United States of America, Mar-2020	5-Mar-2021
Zeta	P.2	GR/484K.V2	20B/S.484K	Brazil, Apr-2020	17-Mar-2021
Eta	B.1.525	G/484K.V3	21D	Multiple countries, Dec-2020	17-Mar-2021
Theta	P.3	GR/1092K.V1	21E	Philippines, Jan-2021	24-Mar-2021
Iota	B.1.526	GH/253G.V1	21F	United States of America, Nov-2020	24-Mar-2021
Kappa	B.1.617.1	G/452R.V3	21B	India, Oct-2020	4-Apr-2021
Lambda	C.37	GR/452Q.V1	20D	Peru, Aug-2020	14-Jun-2021

VOI Lambda

On 14 June 2021, a variant assigned to Pango lineage C.37, GISAID clade GR/452Q.V1, NextStrain clade 20D, was designated as a global VOI, and assigned the WHO label “Lambda”. This variant has been monitored as an alert for an extended period, and upon more information and updated assessments, is now considered as meeting the [VOI working definition](#) based upon evidence of continued emergence and suspected phenotypic implications.

Lambda has been associated with substantive rates of community transmission in multiple countries, with rising prevalence over time concurrent with increased COVID-19 incidence. The earliest sequenced samples were reported from Peru in August 2020. As of 15 June 2021, over 1730 sequences have been uploaded to GISAID from 29 countries/territories/areas in five WHO regions.¹ Elevated prevalence has been noted particularly in South America in countries such as Chile (31% overall prevalence among submitted sequences

since first detected in this location to date), Peru (9%), Ecuador (8%), and Argentina (3%).² Authorities in Peru reported that 81% of COVID-19 cases sequenced since April 2021 were associated with Lambda.³ Argentina reported increasing prevalence of Lambda since the third week of February 2021, and between 2 April and 19 May 2021, the variant accounted for 37% of the COVID-19 cases sequenced.⁴ In Chile, prevalence of Lambda has increased over time, accounting for 32% of sequenced cases reported in the last 60 days – co-circulating at similar rates to variant Gamma (33%), but outcompeting variant Alpha (4%) over the same period.⁵

Lambda carries a number of mutations with suspected phenotypic implications, such as a potential increased transmissibility or possible increased resistance to neutralizing antibodies.⁶ It is characterised by mutations in the spike protein, including G75V, T76I, del247/253, L452Q, F490S, D614G and T859N; however, there is currently limited evidence on the full extent of the impact associated with these genomic changes, and further robust studies into the phenotypic impacts are needed to better understand the impact on countermeasures and to control the spread. Further studies are also required to validate the continued effectiveness of vaccines.

Geographic distribution of VOCs

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing and the sharing of sequences and supporting meta-data, the number of countries/areas/territories reporting VOCs has continued to increase (Figure 4). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

WHO recommendations

Virus evolution continues to be expected, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations, are fundamental to and crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2, including all variants that evolve.

Evidence from multiple countries with extensive transmission of VOCs has indicated that PHSM, including infection prevention and control (IPC) measures in health facilities, have been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

WHO regional overviews

Epidemiological week 7-13 June 2021

African Region

The African Region reported over 95 000 new cases and over 1400 new deaths, a 44% and a 20% increase respectively compared to the previous week. The region reported a marked increase in weekly case incidence for the third consecutive week, with the largest increases in countries in the Southern, Eastern and Northern parts of Africa. The highest numbers of new cases were reported from South Africa (47 934 new cases; 80.8 new cases per 100 000 population; a 48% increase), Zambia (10 792 new cases; 58.7 new cases per 100 000; a 125% increase), and Uganda (8574 new cases; 18.7 new cases per 100 000; a 49% increase).

The highest numbers of new deaths were reported from South Africa (724 new deaths; 1.2 new deaths per 100 000 population; a 28% increase), Kenya (132 new deaths; 0.2 new deaths per 100 000; a 7% increase) and Namibia (88 new deaths; 3.5 new deaths per 100 000; a 1% increase).

Region of the Americas

The Region of the Americas reported over 1.1 million new cases, a similar number to the previous week, and just under 32 000 new deaths, a 7% decrease compared to the previous week. Despite this decrease, high levels of transmission and mortality are still being recorded in many countries in South and Central America. The highest numbers of new cases were reported from Brazil (454 710 new cases; 213.9 new cases per 100 000; similar to the previous week), Argentina (177 693 new cases; 393.2 new cases per 100 000; a 17% decrease), and Colombia (176 661 new cases; 347.2 new cases per 100 000; a 1% increase).

The highest numbers of new deaths were also reported from Brazil (13 393 new deaths; 6.3 new deaths per 100 000; a 14% increase), Argentina (4217 new deaths; 9.3 new deaths per 100 000; a 13% increase), and Colombia (3725 new deaths; 7.3 new deaths per 100 000; similar to the previous week).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 191 000 new cases and over 3300 new deaths, a 5% and a 4% decrease respectively compared to the previous week. While declining weekly case incidence trends have been recorded for the eighth consecutive week, a number of countries across the region are starting to report increasing case and death incidence, including Oman, Tunisia and Afghanistan. The highest numbers of new cases were reported from the Islamic Republic of Iran (59 771 new cases; 71.2 new cases per 100 000; an 11% decrease), Iraq (29 013 new cases; 72.1 new cases per 100 000; a 3% increase), and the United Arab Emirates (14 820 new cases; 149.8 new cases per 100 000; a 6% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (970 new deaths; 1.2 new deaths per 100 000; a 19% decrease), Tunisia (488 new deaths; 4.1 new deaths per 100 000; a 30% increase), and Pakistan (444 new deaths; 0.2 new deaths per 100 000; a 13% decrease).

European Region

The European Region reported over 332 000 new cases, a 13% decrease when compared to the previous week and a declining trend for the ninth consecutive week. The Region reported over 7200 new deaths, a 17% decrease when compared to the previous week. While most countries across the Region continue to see decreasing or stabilizing trends, some countries, such as the Russian Federation, the United Kingdom and Kyrgyzstan have reported increases in case incidence this week compared to the previous week. The highest numbers of new cases were reported from Russian Federation (82 250 new cases; 56.4 new cases per 100 000; a 31% increase), The United Kingdom (46 825 new cases; 69.0 new cases per 100 000; a 52% increase), and Turkey (42 841 new cases; 50.8 new cases per 100 000; an 8% decrease).

The highest numbers of new deaths were reported from Russian Federation (2643 new deaths; 1.8 new deaths per 100 000; a 1% increase), Germany (612 new deaths; 0.7 new deaths per 100 000; a 25% decrease), and Turkey (600 new deaths; 0.7 new deaths per 100 000; a 25% decrease).

South-East Asia Region

The South-East Asia Region reported over 763 000 new cases, a 27% decrease compared to the previous week. Weekly case incidence has been decreasing sharply for five consecutive weeks, largely driven by decreases in the number of cases in a small number of countries. While the number of newly reported cases continues to decrease in India, Bangladesh has reported an increasing trend in cases for the past four weeks. The Region reported over 26 000 new deaths a 12% increase when compared to the previous week. The highest numbers of new cases were reported from India (630 650 new cases; 45.7 new cases per 100 000; a 31% decrease), Indonesia (55 320 new cases; 20.2 new cases per 100 000; a 38% increase), and Nepal (20 348 new cases; 69.8 new cases per 100 000; a 34% decrease).

The highest numbers of new deaths were also reported from India (23 625 new deaths; 1.7 new deaths per 100 000; a 14% increase), Indonesia (1267 new deaths; 0.5 new deaths per 100 000; a 5% increase), and Nepal (514 new deaths; 1.8 new deaths per 100 000; an 18% decrease).

Western Pacific Region

The Western Pacific Region reported over 124 000 new cases and over 2300 new deaths, a 10% and a 7% decrease respectively compared to the previous week. While the region has an overall decreasing trend in cases, some countries, including Fiji, Vietnam and Mongolia are reporting increases and peak numbers of cases. The highest numbers of new cases were reported from the Philippines (46 087 new cases; 42.1 new cases per 100 000; a 1% increase), Malaysia (41 630 new cases; 128.6 new cases per 100 000; a 20% decrease), and Japan (13 499 new cases; 10.7 new cases per 100 000; a 28% decrease).

The highest numbers of new deaths were also reported from the Philippines (920 new deaths; 0.8 new deaths per 100 000; a 9% decrease), Malaysia (553 new deaths; 1.7 new deaths per 100 000; a 14% decrease), and Japan (510 new deaths; 0.4 new deaths per 100 000; a 15% decrease).

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the media briefing on COVID-19 – 14 June 2021](#), the Director-General highlighted that the global decline in cases of COVID-19 reported to WHO masks a worrying increase in cases and deaths in many countries, and that the steep increase in Africa is especially concerning because it is the region with the least access to vaccines, diagnostics and therapeutic oxygen.
- The emergence of more transmissible variants means public health and social measures (PHSM) may need to be more stringent and applied for longer, particularly in areas where vaccination rates remain low. To improve the evidence base on the effectiveness of PHSM, WHO is collecting data globally on which measures are used and the level at which they are applied. WHO has also established a new working group, with the support of Norway, to study the impact of PHSM during COVID-19 and other health emergencies.
- In his [opening remarks at the G7 Summit – 12 June 2021](#), the Director-General said that to end the pandemic, our shared goal must be to vaccinate at least 70% of the world's population by the time the G7 meets again in Germany in 2022. He welcomed the announcement that the G7 countries will donate 870 million vaccine doses, primarily through COVAX. "This is a big help, but we need more, and we need them faster. More than 10 000 people are dying every day."

**Newly reported in this update.*

reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available from official sources.

ation become available.

Variant Beta for Ecuador was excluded this week based on further information received.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Efforts are ongoing to differentiate these in future reports. See also [Annex 3: Data, table and figure notes](#).*

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 758 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#).

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Edition 43, published 8 June 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest \(VOIs\) and Variants of Concern \(VOCs\)](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 6 June 2021

Global case and death incidences continued to decrease with over 3 million new weekly cases and over 73 000 new deaths, a 15% and an 8% decrease respectively, compared to the previous week (Figure 1). The European and South-East Asia Regions reported marked declines in the number of new cases in the past week, whereas the African Region reported an increase compared to the previous week (Table 1). The Region of the Americas as well as the Eastern Mediterranean and the Western Pacific Regions reported similar numbers compared to the previous week. The number of new deaths reported in the past week decreased in the European and South-East Asia Regions and increased in the Western Pacific Region. Death incidences remained stable in the Region of the Americas as well as the Eastern Mediterranean and African Regions. Despite the downward trend in global case and death incidences for a sixth and fifth consecutive week respectively, many countries across all six regions have reported rises in the number of cases and deaths.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 6 June 2021**

**See Annex 3: Data, table and figure notes

The highest numbers of new cases were reported from India (914 539 new cases; 33% decrease), Brazil (449 478 new cases; 7% increase), Argentina (212 975 new cases; 3% decrease), Colombia (175 479 new cases; 17% increase), and the United States of America (99 103 new cases; 35% decrease).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 6 June 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 191 047 (39%)	-1%	68 370 018 (40%)	34 392 (47%)	4%	1 794 865 (48%)

Special Focus: Update on SARS-CoV-2 Variants of Interest (VOIs) and Variants of Concern (VOCs)

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they result in changes in the implementation of public health and social measures (PHSM) by national health authorities. Systems have been established to detect “signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) and assess these based on the risk posed to global public health. Table 2 lists currently designated global VOIs and VOCs. National authorities may choose to designate other variants of local interest/concern. Here we provide an update on emerging evidence surrounding phenotypic characteristics and the geographical distribution of designated VOCs.

On 31 May 2021, [WHO announced new easy-to-say/easy-to-remember VOI and VOC labels](#) to facilitate public communication about SARS-CoV-2 variants and the [1 June 2021 edition](#) of the WEU outlined the changes in labelling of the VOCs and VOIs, as well as updates to the classifications of variants B.1.617.1, B.1.617.3 and B.1.616.

Table 2: SARS-CoV-2 Variants of Concern (VOCs) and Variants of Interest (VOIs), as of 8 June 2021

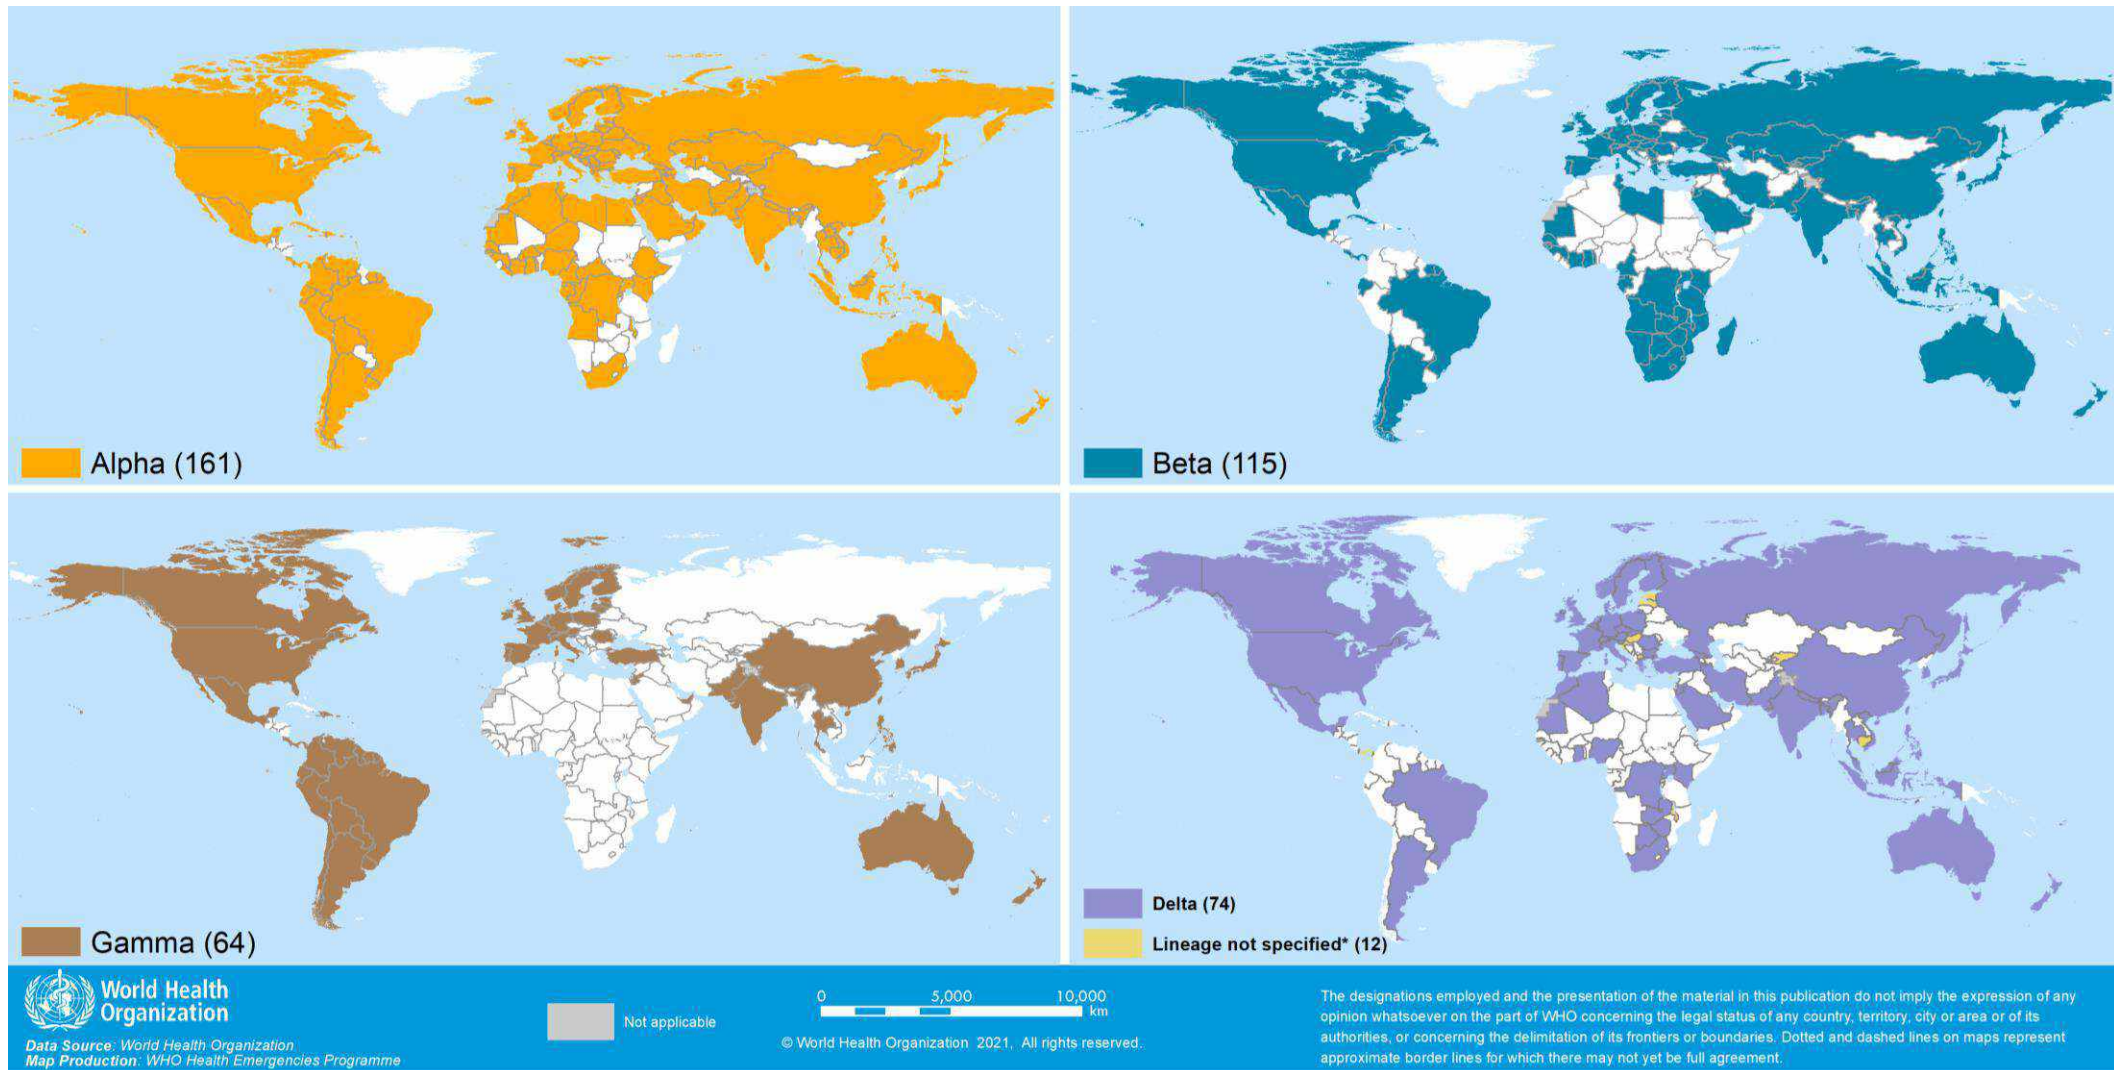

WHO label	Pango lineage	GISAID clade	Nextstrain clade	Earliest documented samples	Date of designation
Variants of Concern (VOCs)					
Alpha	B.1.1.7	GRY (formerly GR/501Y.V1)	20I/501Y.V1	United Kingdom, Sep-2020	18-Dec-2020

Impacts on neutralization by vaccine	<ul style="list-style-type: none"> No/minimal loss: Bharat-Covaxin, Gamaleya-Sputnik V, Moderna-mRNA-1273, Novavax-Covavax, Pfizer BioNTech-Comirnaty, BeijingCNBG-BBIBP-CorV, Sinovac-CoronaVac^{17,38–63} Minimal/moderate loss: AstraZeneca-Vaxzevria^{29,53} 	<ul style="list-style-type: none"> Minimal/modest loss: Beijing CNBG-BBIBP-CorV, Sinovac-CoronaVac, Anhui ZL - Recombinant^{64–66} Minimal to substantial loss: Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty^{17,40,44,46–48,50,52–54,60,62,63,67–73} Moderate to substantial loss: AstraZeneca-Vaxzevria, Gamaleya- Sputnik V, Janssen-Ad26.COV 2.5, Novavax-Covavax^{46,55,70,74} 	<ul style="list-style-type: none"> No/minimal loss:AstraZeneca-Vaxzevria,Sinovac-CoronaVac^{53,75} Minimal/moderate loss: Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty^{17,40,41,50,52,53,59,62,76,77} 	<ul style="list-style-type: none"> Modest/moderate loss: Pfizer BioNTech Comirnaty, Bharat-Covaxin^{60,78,79} (Note: sublineage of B.1.617 not specified in Bharat-Covaxin study) Substantial loss: <i>single dose</i> of AstraZeneca-Vaxzevria⁷⁸

*Generalized findings as compared to previously/co-circulating variants. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.

Figure 3. Countries, territories and areas reporting variants Alpha (B.1.1.7), Beta (B.1.351), Gamma (P.1) and Delta (B.1.617.2), as of 8 June 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs and vaccine performance against VOCs are summarised in Tables 3, as well as in [previous editions](#) of the WEU.

Recent studies of the Delta variant in the United Kingdom of Great Britain and Northern Ireland suggest a possible increased risk of severe disease, and support previous observations of increased transmissibility.⁵ An analysis comparing Delta and Alpha variant confirmed cases in the United Kingdom from 29 March to 20 May 2021 showed the Delta variant was associated with a possible increased risk of hospitalization (hazard ratio 2.61, 95%CI 1.56-4.36), and an increased risk of emergency care attendance or hospitalization (hazard ratio 1.67, 1.25-2.23) within 14 days of specimen collection, as compared to the Alpha variant. A second analysis based on cases reported in the United Kingdom from 29 March to 11 May 2021 (variant data as of 25 May 2021) found that the secondary attack rate was higher among contacts of Delta cases compared to contacts of Alpha cases (2.6% vs. 1.6% among contacts of cases that have travelled; 8.2% vs. 12.4% among contacts of cases that have not travelled). Further analyses are required to better understand and confirm these findings.

VOC impacts on vaccines

Since the [update on VOC impacts on vaccines on 25 May](#), two studies have provided further evidence of the effectiveness of Pfizer BioNTech-Comirnaty vaccine against VOCs. A study from Canada found two doses of the vaccine to be 90% (95% CI: 85-94%) and 88% (95% CI: 61-96%) effective against symptomatic disease ≥ 7 days post second dose caused by variants Alpha and Beta/Gamma, respectively, among adults 16 years and older. Vaccine effectiveness (VE) against hospitalization/death ≥ 0 days post second dose was 94% (95%CI: 55-99%) for Alpha and 100% (95% CI not available) for Beta/Gamma. VE of a single dose of Pfizer BioNTech-Comirnaty against symptomatic disease (≥ 14 days after immunization) was 61% (95% CI: 59-66%), 43% (95% CI: 22-59%), and 61% (95% CI: 53-67%) for Alpha, Beta, and for Gamma, respectively, underscoring the importance of two doses of vaccine in preventing symptomatic disease. Samples bearing the 501Y mutation without the E484K mutation were assumed to be Alpha while samples bearing the 501Y mutation with the E484K mutation were assumed to be either Beta or Gamma.²⁷ Samples bearing the 501Y mutation without the E484K mutation were assumed to be Alpha while samples bearing the 501Y mutation with the E484K mutation were assumed to be either Beta or Gamma.²⁷ Samples bearing the 501Y mutation without the E484K mutation were assumed to be Alpha while samples bearing the 501Y mutation with the E484K mutation were assumed to be either Beta or Gamma.²⁷

A previously highlighted study from Qatar found two doses of Pfizer BioNTech-Comirnaty to be highly effective against Alpha infection (VE 89.5%) and severe disease (VE 100%); the vaccine was also highly effective against severe disease caused by Beta with a VE of 100% but somewhat reduced against infection (VE 75%) due to this variant.²⁴ A follow-up analysis (not yet peer-reviewed) to this study evaluated the effectiveness of one dose of Pfizer BioNTech-Comirnaty against infection and severe disease caused by Alpha and Beta variants. At 1-7 days and 8-14 days post vaccination, low to no effectiveness against infection and severe disease was observed for disease events caused by these variants. At 15-21 days post vaccination, VE estimates against infection and severe disease due to Alpha were 65.5% (95% CI: 58.2-71.5%) and 72.0% (95% CI: 32.0-90.0%), respectively. VE estimates against infection and severe disease due to Beta were 46.5% (95% CI: 38.7-53.3%) and 56.5% (95% CI: 0.0-82.8%), respectively. These findings underscore the importance of two doses in preventing infection and severe disease caused by Alpha and Beta. Of note, infections that were not due to Alpha were assumed to be caused by Beta variant as national surveillance did not detect any other strains circulating during much of the study period.⁸⁰

Two recent studies provide evidence of reduced neutralization capacity of COVID-19 vaccines against variant Delta. One study found a 5.8-fold reduction in neutralization against Delta compared to a reference strain in 159 samples from individuals who received two doses of Pfizer BioNTech-Comirnaty [median time after second dose: 28 days (IQR: 21-37)]; 2.6- and 4.9-fold reductions were observed against Alpha and Beta variants, respectively, relative to the reference strain.⁶⁰ Findings from a second study (not yet peer-reviewed)

show a 3-fold reduction in neutralization capacity against Delta relative to Alpha among sera collected from 16 individuals five weeks after receipt of second dose of Pfizer BioNTech-Comirnaty; a 16-fold reduction was observed against Beta relative to Alpha. Most samples (81-100%) were able to neutralize Alpha, Beta and Delta five weeks after receipt of the second dose; findings remained consistent at 13 weeks after second dose with the exception of the Beta strain whereby only 46% of samples were able to neutralize the variant. Authors also found that a single dose of AstraZeneca-Vaxzevria, while able to neutralize Alpha, was less effective at neutralizing Beta or Delta.⁷⁸

Two recent studies (not yet peer reviewed) provide evidence of the impact of heterologous vaccination on neutralization capacity against variants. In both studies, individuals received AstraZeneca-Vaxzevria as a first dose followed by a Pfizer BioNTech-Comirnaty booster. The first of these studies compared 26 individuals receiving heterologous vaccination to 14 individuals receiving two doses of Pfizer BioNTech-Comirnaty. Overall, authors report a strong neutralization response in heterologous vaccinated individuals against Alpha, Beta and B.1.617 (lineage not specified) exceeding neutralization titers of the homologous vaccination group, though the difference for B.1.617 was not statistically significant. Results also show that, among the heterologous group, a two-fold reduction in neutralization capacity was observed against Beta relative to Alpha, though neutralization was still achieved; no such reduction was observed for B.1.617. In addition, CD4+ or CD8+ T cells were detected two weeks after heterologous vaccination, with results similar to those from studies evaluating a single dose of AstraZeneca-Vaxzevria and homologous Pfizer BioNTech-Comirnaty vaccination.⁸¹ The second study compared the AstraZeneca-Vaxzevria/Pfizer BioNTech-Comirnaty heterologous group to a homologous group receiving two doses of AstraZeneca-Vaxzevria and found higher neutralization against Alpha, Beta and Gamma in the heterologous group. Increased CD4+ and CD8+ T cell reactivity was also observed in the heterologous group.⁸² Together, these studies provide evidence that a heterologous vaccination regimen is at least as protective as homologous vaccinations.

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs has continued to increase (Figure 3, Annex 2). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries

Public health authorities are encouraged to continue to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and in the investigation of unusual epidemiological events. [Environmental surveillance](#) has the potential to support other early warning surveillance systems for monitoring the spread of SARS-CoV-2 infections, including variants. A recent study in the United Kingdom demonstrated the ability to detect co-circulating SARS-CoV-2 variants and identify changes in viral RNA sequences in wastewater.⁸³ In Spain, weekly wastewater estimates of the proportion of variant Alpha in 32 different locations reflected the trends in reported sequenced clinical cases in most regions. Moreover, wastewater surveillance allowed the identification of variant Alpha circulation in new areas within Spain before detection by the public health authorities using clinical specimens.⁸⁴

WHO recommendations

Virus evolution is expected, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations, are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that PHSM, including infection prevention and control (IPC) measures in health facilities, have been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National

and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

WHO regional overviews

African Region

The African Region reported just under 66 000 new cases, a 25% increase compared to the previous week, and over 1100 new deaths, a number similar to that of the previous week. The region reported an increase in weekly case incidence by over 20% for a second consecutive week, while death incidence increased for a third consecutively, though by a lower rate. The highest numbers of new cases were reported from South Africa (32 421 new cases; 54.7 new cases per 100 000 population; a 22% increase), Uganda (5745 new cases; 12.6 new cases per 100 000; a 137% increase), and Zambia (4789 new cases; 26.0 new cases per 100 000; a 191% increase).

The highest numbers of new deaths were reported from South Africa (566 new deaths; 1.0 new deaths per 100 000 population; a 4% decrease), Kenya (123 new deaths; 0.2 new deaths per 100 000; a 34% increase), and Namibia (87 new deaths; 3.4 new deaths per 100 000; a 58% increase).

Region of the Americas

The Region of the Americas reported just under 1.2 million new cases and over 34 000 new deaths, both figures similar to those of the previous week. Case incidence overall continued to decrease since mid-April 2021; however, high numbers in both cases and deaths continue to be observed in many countries, most notably in parts of South and Central America. The highest numbers of new cases were reported from Brazil (449 478 new cases; 211.5 new cases per 100 000; a 7% increase), Argentina (212 975 new cases; 471.2 new cases per 100 000; a 3% decrease), and Colombia (175 479 new cases; 344.9 new cases per 100 000; a 17% increase).

The highest numbers of new deaths were reported from Brazil (11 797 new deaths; 5.5 new deaths per 100 000; a 7% decrease), Mexico (5496 new deaths; 4.3 new deaths per 100 000; a 203% increase), and Argentina (3718 new deaths; 8.2 new deaths per 100 000; a 13% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 202 000 new cases and over 3500 new deaths. Overall, weekly case and death incidence has continued a general downward trend; however, surges in transmission have been observed in several countries. The highest numbers of new cases were reported from the Islamic Republic of Iran (67 533 new cases; 80.4 new cases per 100 000; a 3% decrease), Iraq (28 070 new cases; 69.8 new cases per 100 000; a 5% decrease), and Pakistan (14 272 new cases; 6.5 new cases per 100 000; a 24% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1200 new deaths; 1.4 new deaths per 100 000; a 12% decrease), Pakistan (509 new deaths; 0.2 new deaths per 100 000; similar to the previous week), and Tunisia (374 new deaths; 3.2 new deaths per 100 000; a 5% decrease).

European Region

The European Region reported over 368 000 new cases and just under 8900 new deaths, a 17% and a 21% decrease respectively compared to the previous week. Steep declines in both case and death incidences continued for a tenth and eighth consecutive week, respectively. The highest numbers of new cases were reported from the Russian Federation (62 995 new cases; 43.2 new cases per 100 000; a 2% increase), France (47 528 new cases; 73.1 new cases per 100 000; a 22% decrease), and Turkey (46 616 new cases; 55.3 new cases per 100 000; a 19% decrease).

The highest numbers of new deaths were reported from the Russian Federation (2625 new deaths; 1.8 new deaths per 100 000; a number similar to that of the previous week), Germany (816 new deaths; 1.0 new deaths per 100 000; a 20% decrease), and Turkey (797 new deaths; 0.9 new deaths per 100 000; a 34% decrease).

South-East Asia Region

The South-East Asia Region reported over 1.0 million new cases and over 23 000 new deaths, a 31% and a 21% decrease respectively compared to the previous week. Overall, case and death incidences continued to sharply decline in line with trends in India; however, marked increases have been observed elsewhere in the region. The highest numbers of new cases were reported from India (914 539 new cases; 66.3 new cases per 100 000; a 33% decrease), Indonesia (40 280 new cases; 14.7 new cases per 100 000; similar to the previous week), and Nepal (31 678 new cases; 108.7 new cases per 100 000; a 34% decrease).

The highest numbers of new deaths were reported from India (20 787 new deaths; 1.5 new deaths per 100 000; a 22% decrease), Indonesia (1187 new deaths; 0.4 new deaths per 100 000; a 12% increase), and Nepal (636 new deaths; 2.2 new deaths per 100 000; a 37% decrease).

Western Pacific Region

The Western Pacific Region reported over 138 000 new cases, a number similar to that of the previous week, and over 2400 new deaths, a 19% increase compared to the previous week. During the past week, the region recorded its highest incidence of deaths and second highest cases incidence to date. The highest numbers of new cases were reported from Malaysia (52 040 new cases; 160.8 new cases per 100 000; a 3% decrease), the Philippines (45 681 new cases; 41.7 new cases per 100 000; a 19% increase), and Japan (18 649 new cases; 14.7 new cases per 100 000; a 32% decrease).

The highest numbers of new deaths were reported from the Philippines (1010 new deaths; 0.9 new deaths per 100 000; a 30% increase), Malaysia (641 new deaths; 2.0 new deaths per 100 000; a 42% increase), and Japan (603 new deaths; 0.5 new deaths per 100 000; a 12% decrease).

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the media briefing on COVID-19 – 7 June 2021](#), the Director-General reminded us that although the number of cases and deaths have been decreasing for over a month, we are increasingly seeing a two-track pandemic: where many countries still face an extremely dangerous situation, while some of those with the highest vaccination rates are starting to talk about ending restrictions.
- On 12 June, leaders of G7 countries will meet for their annual summit. The Director-General urges the G7 not just to commit to sharing doses, but to commit to sharing them in June and July. The inequitable distribution of vaccines has allowed the virus to continue spreading, increasing the chances of a variant emerging that renders vaccines less effective and the biggest barrier to ending the pandemic remains sharing: of doses, of resources, of technology.

*Newly reported in this update.

reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

ation become available.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Efforts are ongoing to differentiate these in future reports. See also [Annex 3: Data, table and figure notes](#).

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 758 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#).

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Edition 42, published 1 June 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest \(VOIs\) and Variants of Concern \(VOCs\)](#)
- [Special focus: Early lessons from country implementation of COVID-19 vaccination](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 30 May 2021

The number of new COVID-19 cases and deaths continues to decrease, with over 3.5 million new cases and 78 000 new deaths reported globally in the past week; a 15% and 7% decrease respectively, compared to the previous week (Figure 1). The European and South-East Asia Regions reported the largest decline in new cases and deaths in the past week, while case incidence increased in the African and Western Pacific regions (Table 1). The numbers of cases reported by the Americas and Eastern Mediterranean Regions were similar to those reported in the previous week. An increase in death incidence was reported in the African Region, whereas the Europe and the Eastern Mediterranean Regions reported decreases, and the reported death incidence in the Western Pacific and the Americas Regions was similar to the death incidence in the previous week. Although the number of global cases and deaths continued to decrease for a fifth and fourth consecutive week respectively, case and death incidences remain at high levels and significant increases have been reported in many countries in all regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 30 May 2021**

**See [Annex 3: Data, table and figure notes](#)

The highest numbers of new cases were reported from India (1 364 668 new cases; 26% decrease), Brazil (420 981 new cases; 7% decrease), Argentina (219 910 new cases; 3% increase), the United States of America (153 587 new cases; 18% decrease), and Colombia (150 517 new cases; 40% increase).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 30 May 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 198 427 (34%)	-2%	67 178 933 (40%)	31 286 (40%)	-1%	1 646 407 (47%)
Europe	430 945 (12%)	-26%	54 244 552 (32%)	11 113 (14%)	-17%	1 148 766 (33%)

Special Focus: Update on SARS-CoV-2 Variants of Interest (VOIs) and Variants of Concern (VOCs)

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 alter clinical presentation and severity, or if they show increases in transmissibility that require national health authorities to implement strengthened public health and social measures (PHSM) to control disease spread. Systems have been established in WHO to detect “signals” of potential Variants of Concern (VOCs) or Variants of Interest (VOIs) and assess these based on the risk posed to global public health. Here we provide updates on new WHO labels and classifications of VOCs and VOIs, as well as the updated geographical distribution of VOCs. National authorities may choose to designate other variants of local interest/concern.

New easy-to-say VOI and VOCs labels for public communication

On 31 May 2021, [WHO announced new easy-to-say/easy-to-remember VOI and VOC labels](#) to facilitate public communication about SARS-CoV-2 variants. The need for easy-to-say labels of SARS-CoV-2 VOI and VOC arose for several reasons, including:

- the existence of different genomic nomenclature systems, which serve important scientific purposes but complicate public communication around variants due to the complexities of the labels assigned (e.g., B.1.617.2, 21A/S:478K),
- the common but potentially stigmatizing use of the name of the country or area of first detection of a variant as an easily recognizable label.

WHO has now assigned labels based upon the Greek alphabet to globally classified VOCs and VOIs (Table 2), and will sequentially assign new labels for newly-designated global VOCs and VOIs in the future. If all 24 letters become assigned, other lists of labels will be announced by WHO. As VOIs and VOCs are reclassified based on the evolving situation, it is expected that these will retain their label, and labels of former VOIs/VOCs will not be reused for labeling new emerging variants.

We recommend Member States, health authorities, media and others communicating on SARS-CoV-2 variants to adopt the WHO labels in public communication as soon as practical. Importantly, these labels do not replace the three current nomenclature systems for tracking and scientific reporting of SARS-CoV-2 genetic evolution: [GISAID](#), [Nextstrain](#), and [Pango](#) – these systems remain critical and will continue to be used in scientific communications.

Recent changes to the VOIs and VOCs classifications

As the global public health risks posed by specific SARS-CoV-2 variants becomes better understood and evolves, WHO will continue to update the list of global VOIs and VOCs. This is necessary to adjust to the emergence of new variants, their changing epidemiology (e.g., the incidence of some variants is rapidly declining), and our understanding of their phenotypic impacts as new evidence becomes available and is shared.

First, available information allows for the delineation of VOC B.1.617. B.1.617 viruses are divided in three lineages: B.1.617.1, B.1.617.2 and B.1.617.3. Available findings for lineages B.1.617.1 and B.1.617.2 were initially used to designate B.1.617 a global VOC on 11 May 2021. Since then, it has become evident that greater public health risks are currently associated with B.1.617.2, while lower rates of transmission of other lineages have been observed. To reflect this updated information, B.1.617 has been delineated as follows:

- B.1.617.2 remains a VOC and labelled variant Delta – we continue to observe significantly increased transmissibility and a growing number of countries reporting outbreaks associated with this variant. Further studies into the impact of this variant remain a high priority for WHO.
- B.1.617.1 has been reclassified to a VOI and labelled variant Kappa – while also demonstrating increased transmissibility (in specified locations), global prevalence appears to be declining. This variant will continue to be monitored and reassessed regularly.
- B.1.617.3 is no longer classified as either a VOI or VOC – relatively few reports of this variant have been submitted to date.

Second, variant B.1.616, which was first detected in France following investigations into an unusual cluster of cases in a hospital, is no longer classified as a VOI. Local authorities have reported that the outbreak has been controlled, and no further detections within or outside of France have been reported since late-April 2021.¹ Further local and regional monitoring remains prudent, given B.1.616 was associated with potential increased disease severity and reduced detections via nasopharyngeal samples.²

Variants no longer classified as VOCs or VOIs will continue to be monitored as part of the overall evolution of SARS-CoV-2, and may be reassessed pending new evidence indicating an increased public health risk.

Table 2: SARS-CoV-2 Variants of Concern (VOCs) and Variants of Interest (VOIs), as of 31 May 2021

WHO label	Pango lineage	GISAID clade	Nextstrain clade	Earliest documented samples	Date of designation
Variants of Concern (VOCs)					
Alpha	B.1.1.7	GRY (formerly GR/501Y.V1)	20I/501Y.V1	United Kingdom, Sep-2020	18-Dec-2020
Beta	B.1.351	GH/501Y.V2	20H/501Y.V2	South Africa, May-2020	18-Dec-2020
Gamma	P.1	GR/501Y.V3	20J/501Y.V3	Brazil, Nov-2020	11-Jan-2021
Delta	B.1.617.2	G/452R.V3	21A/S:478K	India, Oct-2020	VOI: 4-Apr-2021 VOC: 11-May-2021
Variants of Interest (VOIs)					
Epsilon	B.1.427/ B.1.429	GH/452R.V1	20C/S.452R	United States of America, Mar-2020	5-Mar-2021
Zeta	P.2	GR	20B/S.484K	Brazil, Apr-2020	17-Mar-2021
Eta	B.1.525	G/484K.V3	20A/S484K	Multiple countries, Dec-2020	17-Mar-2021
Theta	P.3	GR	20B/S:265C	Philippines, Jan-2021	24-Mar-2021
Iota	B.1.526	GH	20C/S:484K	United States of America, Nov-2020	24-Mar-2021
Kappa	B.1.617.1	G/452R.V3	21A/S:154K	India, Oct-2020	4-Apr-2021

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs has continued to increase (Figures 3, Annex 2). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

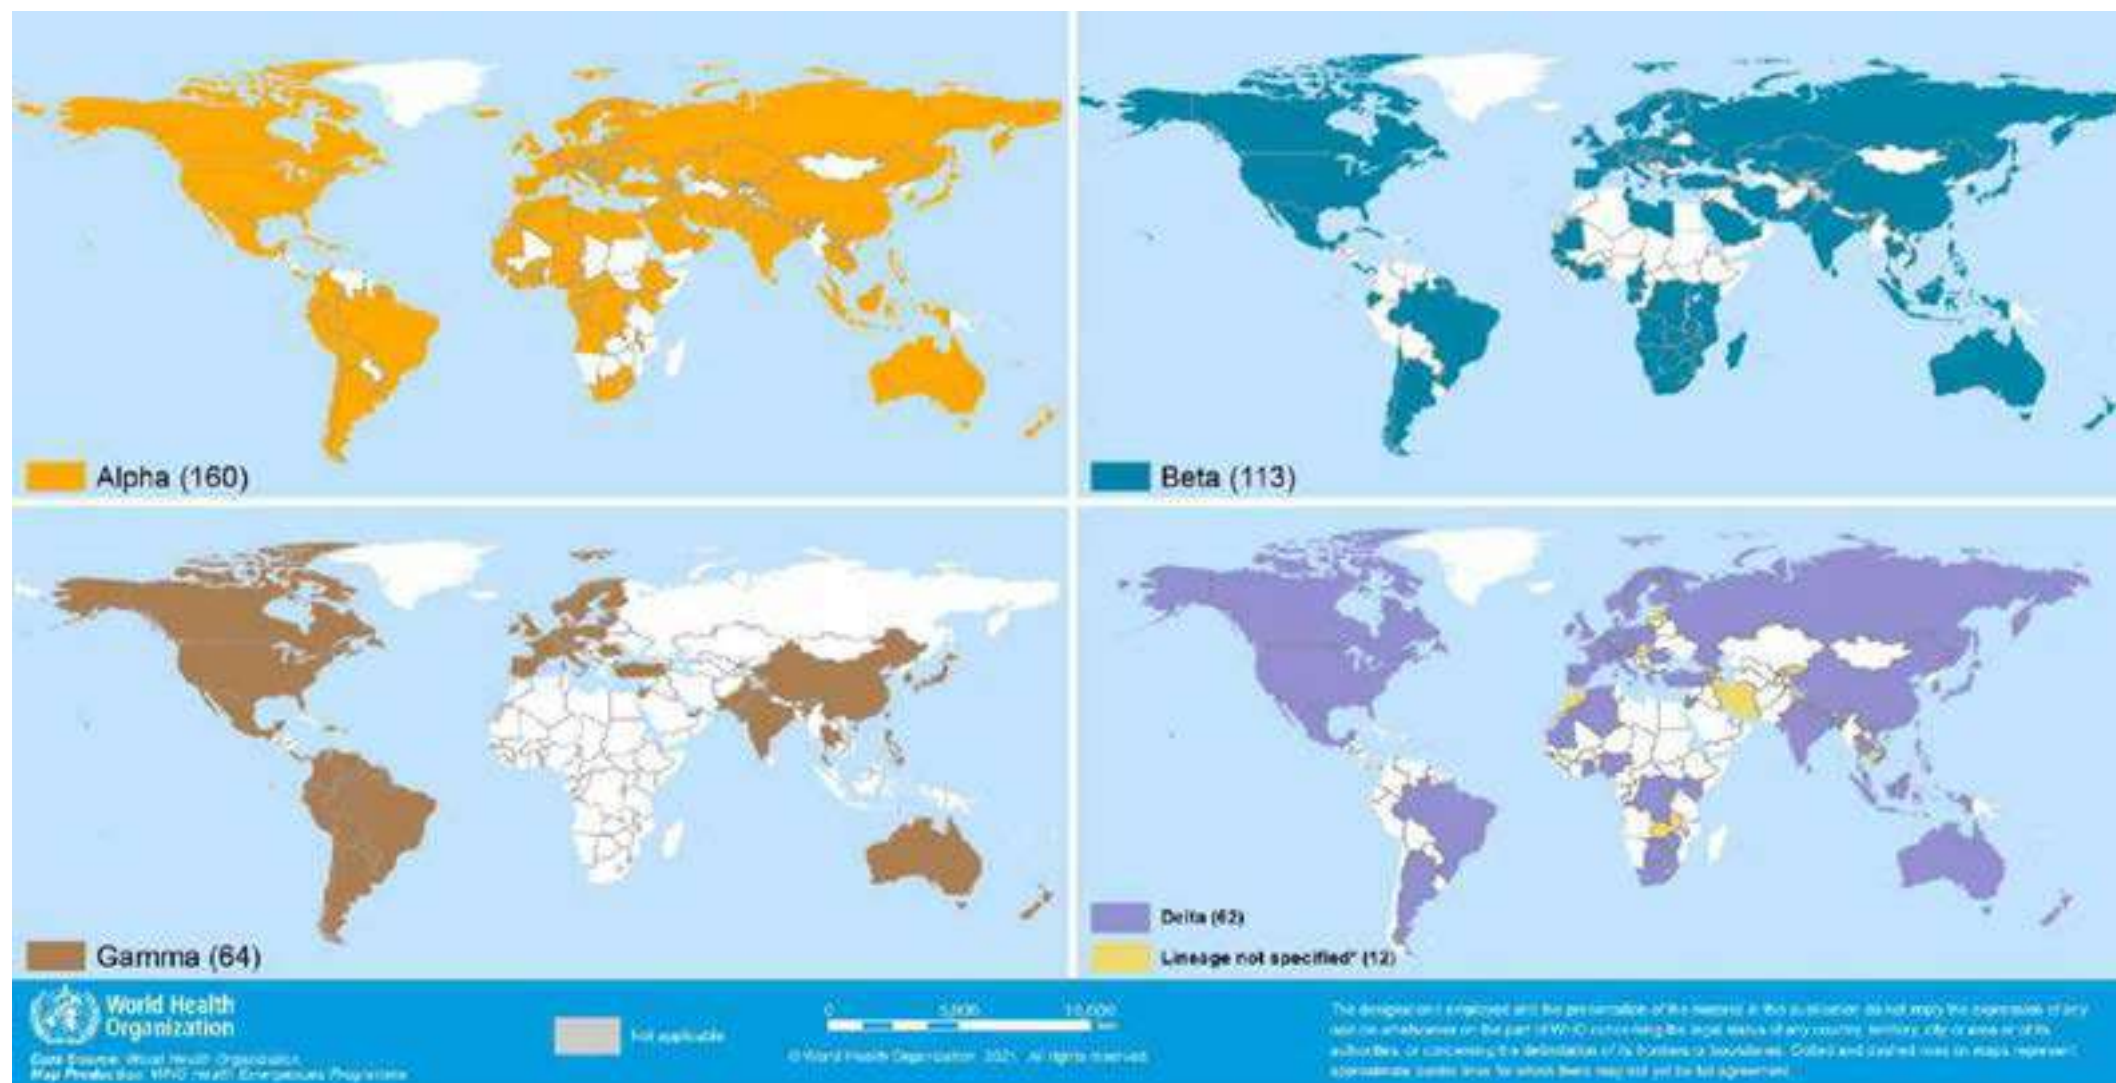

WHO recommendations

Virus evolution is expected, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response](#) Plan, as well as avoiding introductions into animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the PHSM, including infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

Figure 3. Countries, territories and areas reporting variants Alpha (B.1.1.7), Beta (B.1.351), Gamma (P.1) and Delta (B.1.617.2), as of 1 June 2021**

*Includes countries/territories/areas reporting the detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available.

**Countries/territories/areas highlighted include both official and unofficial reports of VOC detections, and do not presently differentiate between detections among travellers (e.g., at Points of Entry) or local community cases. Please see [Annex 2](#) for further details.

Special focus: Early lessons from country implementation of COVID-19 vaccination

Safe and effective vaccines, together with non-pharmaceutical interventions are a game-changing tool in the response to the COVID-19 pandemic. As of 26 May 2021, over 1.5 billion vaccine doses have been administered globally, and over 736 million individuals have received at least one dose (see the [WHO COVID-19 Dashboard](#) for the latest figures). However, vaccination rates are not uniform across countries. The lowest-income countries had access to vaccines later than higher-income countries, and have vaccinated a substantially lower proportion of their target populations.³ We briefly summarize early lessons learned by thematic areas and share qualitative insights gained during the early phases of rolling out COVID-19 vaccines, based on anecdotal reports from regional early learning webinars and discussions with countries, particularly in low-and-middle-income countries (LMICs).

Planning and coordination

Most LMICs prepared National Deployment and Vaccination Plans in anticipation of vaccine supply becoming available. They also established governance structures and coordination processes for planning and overseeing deployment of vaccination activities as part of national response plans. In several countries, engaging with the offices of heads of state facilitated collaboration across health programmes and sectors, which enabled coordinated vaccination.

Identifying and prioritizing groups at the highest risk of exposure or severe outcomes facilitated operational planning. While many countries were able to roughly estimate the size of their priority target groups, information on who they are and where they resided was often unknown. Several countries established digital platforms and used community mobilizers to identify and pre-register priority target groups to facilitate vaccine delivery.

The findings from [scenario-based simulation exercises](#) or drills helped identify unanticipated operational bottlenecks, and were used to update operational plans. At the subnational level, micro plans facilitated vaccine roll-out and session planning, through estimation of the target population size at each administrative level, requisite resources including vaccine doses, supplies and human resources. When such micro plans did not exist or were inadequately prepared at the district and lower administrative levels, it contributed to delayed or slower vaccine roll-out.

Costing and financing

While costing tools were developed to assist countries in estimating vaccine and operational costs, these tools were complex, and many countries lacked the capacity to use them to develop timely and robust cost estimates. Some LMICs were quickly able to mobilize domestic resources to support vaccine rollout, whereas other LMIC governments did not allocate adequate domestic resources. In the past, vaccination for epidemics was accompanied by external support to partially cover operational costs. This was not the case with the COVID-19 vaccine roll-out. The dependency on donors and failure to secure funds in time led to delays in conducting health worker training, compromise on the quality of these trainings, or lowered motivation among health workers due to delayed payment of salaries. In addition, disbursement and distribution of funds to the lowest administrative levels was not streamlined in some countries, leading to a lack of funds, even though funds were available at the national level.

³ pandem-ic. 2021. Vaccination by income. Available from: <https://pandem-ic.com/vaccination-trackers/>

Supply chain and logistics

Most LMICs utilized findings from national Effective Vaccine Management (EVM) assessments and benefited from support by Gavi, the Vaccine Alliance, to optimize their cold chain equipment. Therefore, most had sufficient cold chain capacity to handle the initial shipment of vaccines. Several countries also successfully managed vaccines requiring ultra-cold chain storage and transport; some of them using equipment procured for Ebola vaccines.

Several countries had multiple vaccine products through donations, the COVAX facility, and direct procurement from manufacturers. Managing multiple vaccines with different cold chain requirements without vaccine vial monitors led to logistical challenges. A few of these products had not received WHO Emergency Use Listing and countries did not have the requisite information on product characteristics to enable logistical planning. The initial doses of vaccines that countries received had a relatively short shelf-life of six months at the time of release, often with a shorter shelf-life at the time of delivery to countries. Where there was slow roll-out of vaccines, it was challenging to use them in a timely manner. On occasion, vaccines were re-distributed to other countries to avoid wastage.

Vaccine delivery

While most LMICs had experience with conducting mass vaccination campaigns, Infection Prevention and Control (IPC) at vaccination sites added some challenges to maintain a smooth workflow. Countries provided safe spaces for observation of vaccinees for severe allergic reactions following vaccination, and trained personnel and provided supplies to manage such reactions. Several countries reported lower than expected turn-out at sessions due to vaccine hesitancy, resulting in a high volume of open vials to be wasted.

Demand creation and hesitancy

Early communication to create awareness and prepare communities for the vaccine roll-out, as well as public vaccination of the political and religious leaders improved vaccine uptake. Several countries also successfully utilized social media to heighten public awareness. However, not all countries had the capacity to cope with the magnitude of misinformation or disinformation being disseminated on media platforms and to mount a timely and comprehensive response.

Hesitancy, especially among health and care workers, driven by fear of adverse effects of specific products reported in the media, further fuelled by suspension of some vaccines in high-income countries contributed to low vaccine uptake. Hesitancy among health and care workers was reported to have a ripple effect in other priority groups.

Digital monitoring

Digital registration and data monitoring systems played a key role in monitoring vaccination, generating digital vaccination certificates in several countries, and sending reminders for follow-up vaccination. Digital pre-registration systems, where established, also improved operational flow and enabled the achievement of vaccination targets for each session. However, the lack of digital tools for data entry at the service delivery points impeded data collection in a few countries. In at least one country where hybrid paper-based and digital platforms were used, the lack of proper planning led to inadequate numbers of data entry clerks and delayed data entry and transmission. Several countries reported delayed and incomplete reporting from the lower administrative levels and the limited granular and timely data may have prohibited operational decisions.

Safety monitoring

Most countries leveraged the existing safety surveillance system for immunization to establish reporting of adverse events following vaccination and regularly reported data to WHO and global pharmacovigilance

databases. A few countries lacked the capacity to investigate and conduct causality assessments of serious adverse events and in some, key information was not collected to enable adequate investigation. In other instances, decisions to halt vaccination following a reported death contributed to misperceptions about the safety of the vaccine.

Lessons learned

Lessons learned from the early phases of vaccine introduction will inform ongoing vaccination activities. Sharing early lessons through periodic webinars and peer-to-peer exchanges allowed countries to adopt best practices or successfully implement solutions to operational challenges. Additionally, WHO and partner agencies have used these insights to develop or update guidance and information notes to support countries. In the area of costing and financing, the [COVID-19 Vaccine Introduction and deployment Tool \(CVIC\)](#) was updated and a mechanism to provide direct technical support to countries was established to help improve operational cost estimates. New sources of funding are being developed to support LMICs with filling budgetary gaps to meet immediate operational needs and longer-term financing. Insights from the early introduction of COVID-19 vaccination can further be leveraged to create more resilient immunization systems, foster greater integration in primary health care delivery, and accelerate the implementation of the life-course approach to deliver a package of primary health care interventions.

WHO regional overviews

African Region

The African Region reported over 52 000 new cases and over 1100 new deaths, a 22% and an 11% increase respectively compared to the previous week. Case incidence increased after four consecutive weeks of a plateau in new weekly cases. The highest numbers of new cases were reported from South Africa (26 498 new cases; 44.7 new cases per 100 000 population; a 24% increase), Uganda (2424 new cases; 5.3 new cases per 100 000; a 191% increase), and Kenya (2377 new cases; 4.4 new cases per 100 000; a 13% decrease).

The highest numbers of new deaths were reported from South Africa (591 new deaths; 1.0 new deaths per 100 000 population; similar to the number reported in the previous week), Kenya (92 new deaths; 0.2 new deaths per 100 000; a 92% increase), and Ethiopia (75 new deaths; 0.1 new deaths per 100 000; an 18% decrease).

Region of the Americas

The Region of the Americas reported just under 1.2 million new cases and over 31 000 new deaths, figures similar to those of the previous week. The number of new cases has remained relatively stable for a fourth consecutive week, while the number of deaths has remained stable for a third consecutive week. The highest numbers of new cases were reported from Brazil (420 981 new cases; 198.1 new cases per 100 000; a 7% decrease), Argentina (219 910 new cases; 486.6 new cases per 100 000; a 3% increase), and the United States of America (153 587 new cases; 46.4 new cases per 100 000; an 18% decrease).

The highest numbers of new deaths were reported from Brazil (12 736 new deaths; 6.0 new deaths per 100 000; a 7% decrease), the United States of America (4596 new deaths; 1.4 new deaths per 100 000; a 14% increase), and Colombia (3488 new deaths; 6.9 new deaths per 100 000; similar to the number reported in the previous week).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 212 000 new cases, similar to the number reported in the previous week, and over 3500 new deaths, an 18% decrease compared to the previous week. While small decreases have been seen in case incidence for the past three weeks, death incidence continued a steep decline for a fifth consecutive week. The highest numbers of new cases were reported from the Islamic Republic of Iran (69 331 new cases; 82.5 new cases per 100 000; a 17% decrease), Iraq (29 459 new cases; 73.2 new cases per 100 000; an 8% increase), and Bahrain (20 829 new cases; 1224.1 new cases per 100 000; a 32% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1360 new deaths; 1.6 new deaths per 100 000; a 22% decrease), Pakistan (503 new deaths; 0.2 new deaths per 100 000; a 29% decrease), and Tunisia (392 new deaths; 3.3 new deaths per 100 000; a 3% decrease).

European Region

The European Region reported just under 431 000 new cases and over 11 000 new deaths, a 26% and a 17% decrease respectively compared to the previous week. The number of cases and deaths have steeply decreased for the past six and seven weeks respectively. The highest numbers of new cases were reported from the Russian Federation (61 937 new cases; 42.4 new cases per 100 000; similar to the number reported in the previous week), France (60 600 new cases; 93.2 new cases per 100 000; a 26% decrease), and Turkey (57 330 new cases; 68.0 new cases per 100 000; a 20% decrease).

The highest numbers of new deaths were reported from the Russian Federation (2680 new deaths; 1.8 new deaths per 100 000; a 3% increase), Turkey (1200 new deaths; 1.4 new deaths per 100 000; a 22% decrease), and Ukraine (1104 new deaths; 2.5 new deaths per 100 000; a 15% decrease).

South-East Asia Region

The South-East Asia Region reported over 1.5 million new cases and over 29 000 new deaths, a 24% and an 8% decrease respectively compared to the previous week. Case incidence continued to follow a sharp decline for a third consecutive week, and death incidence decreased for the first time since early March 2021, primarily driven by trends reported in India. The highest numbers of new cases were reported from India (1 364 668 new cases; 98.9 new cases per 100 000; a 26% decrease), Nepal (47 779 new cases; 164.0 new cases per 100 000; an 18% decrease), and Indonesia (39 986 new cases; 14.6 new cases per 100 000; a 20% increase).

The highest numbers of new deaths were reported from India (26 706 new deaths; 1.9 new deaths per 100 000; an 8% decrease), Indonesia (1057 new deaths; 0.4 new deaths per 100 000; a 15% decrease), and Nepal (1010 new deaths; 3.5 new deaths per 100 000; a 22% decrease).

Western Pacific Region

The Western Pacific Region reported over 139 000 new cases, a 6% increase compared to the previous week and just under 2100 new deaths, a similar number to the previous week. The numbers of both cases and deaths remain at the highest levels since the beginning of the pandemic. The highest numbers of new cases were reported from Malaysia (53 419 new cases; 165.0 new cases per 100 000; a 38% increase), the Philippines (38 362 new cases; 35.0 new cases per 100 000; a 4% decrease), and Japan (27 400 new cases; 21.7 new cases per 100 000; a 24% decrease).

The highest numbers of new deaths were reported from the Philippines (776 new deaths; 0.7 new deaths per 100 000; a 13% decrease), Japan (684 new deaths; 0.5 new deaths per 100 000; a 12% decrease), and Malaysia (451 new deaths; 1.4 new deaths per 100 000; a 35% increase).

Key weekly updates

WHO Director-General's key messages

- In his [opening remarks at the media briefing on COVID-19 – 28 May 2021](#), the Director-General called on world leaders to support a massive push to vaccinate at least 10% of the population of every country by September, and 30% by the end of the year. If countries immediately share doses with COVAX, and if manufacturers prioritize COVAX, this target can be reached and lives saved.
- Ultimately, the fastest way to bring this pandemic to an end is to dramatically increase global manufacturing of vaccines, tests, treatments and other medical supplies, and ensure equitable access. A year ago, more than 40 Heads of State joined WHO to form C-TAP, the COVID-19 Technology Access Pool.
- In his [closing remarks at the 74th World Health Assembly](#), the Director-General reminded that the theme of this Assembly was “Ending this pandemic, preventing the next: building together a healthier, safer and fairer world” while stressing that we still have a lot of work to do to end this pandemic. The tailored and consistent use of public health measures, in combination with equitable vaccination, remains the way out.

**Newly reported in this update. Columns for B.1.617.1 (Kappa) and B.1.617.3 were removed this week according to changes in VOC designation.*

reflects countries/territories/areas reporting detection of B.1.617 without further specification of lineage at this time. These will be reallocated as further details become available. that information for this variant was received by WHO from official sources.

indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

Variants Gamma for Bangladesh and Delta for Panama were excluded this week based on further information received.

***Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Efforts are ongoing to differentiate these in future reports. See also [Annex 3: Data, table and figure notes](#).*

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly.

A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 758 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#).

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Edition 41, published 25 May 2021

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest \(VOIs\) and Variants of Concern \(VOCs\)](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Data as of 23 May 2021

Over the past week, the number of new cases and deaths continued to decrease, with over 4.1 million new cases and 84 000 new deaths reported; a 14% and 2% decrease, respectively, compared to the previous week (Figure 1). The European Region reported the largest decline in new cases and deaths in the past week, followed by the South-East Asia Region (Table 1). The numbers of cases reported by the Americas, Eastern Mediterranean, African, and Western Pacific Regions were similar to those reported in the previous week. The Western Pacific Region reported the largest increase in the number of deaths, while other regions reported decreases or similar numbers to the previous week. Despite a declining global trend over the past four weeks, incidence of COVID-19 cases and deaths remain high, and substantial increases have been observed in many countries throughout the world.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 23 May 2021**

**See [Annex 3: Data, table and figure notes](#)

The highest numbers of new cases in the last seven days were reported from India (1 846 055 new cases; 23% decrease), Brazil (451 424 new cases; 3% increase), Argentina (213 046 new cases; 41% increase), the United States of America (188 410 new cases; 20% decrease), and Colombia (107 590 new cases; 7% decrease).

Special Focus: Update on SARS-CoV-2 Variants of Interest (VOIs) and Variants of Concern (VOCs)

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they result in changes in public health and social measures (PHSM) implementation by national health authorities. Globally, systems have been established and are being strengthened to detect “signals” of potential Variants of Interest (VOIs) or Variants of Concern (VOCs) and assess these based on the risk posed to global public health. Table 2 lists currently designated global VOCs and VOIs. National authorities may choose to designate other variants of local interest/concern. Here we provide an update on emerging evidence surrounding phenotypic characteristics (Table 3) and the geographical distribution of designated VOCs.

Table 2: SARS-CoV-2 Variants of Concern (VOCs) and Variants of Interest (VOIs), as of 25 May 2021

PANGO lineage Nextstrain clade GISAID clade	Alternate name	First detected in	Earliest samples	Characteristic spike mutations
Variants of Concern (VOCs)				
B.1.1.7 20I/501Y.V1 GR/501Y.V1	VOC 202012/01	United Kingdom	Sep 2020	69/70del, 144del, N501Y, A570D, D614G, P681H, T716I, S982A, D1118H

* B.1.617 viruses are divided in three lineages (B.1.617.1, B.1.617.2 and B.1.617.3). Findings for lineages B.1.617.1 and B.1.617.2 were mainly used to designate B.1.617 a global VOC. Once more information becomes available, specific lineages may be designated.

Phenotypic characteristics

Available evidence on phenotypic impacts of VOCs and vaccine performance against VOCs are summarised in Tables 3 and 4. Further discussion on impacts is also provided in previous editions of our [COVID-19 Weekly Epidemiological Update](#).

Table 3: Summary of phenotypic impacts* of Variants of Concern (VOCs), as of 25 May 2021

VOC (lineage)	B.1.1.7	B.1.351	P.1	B.1.617
Transmissibility	Increased transmissibility ¹ , Increased secondary attack rate ¹	Increased transmissibility ²	Increased transmissibility ¹	Increased transmissibility ^{3,4}
Disease severity	Not confirmed; possible increased risk of hospitalization ⁵ , severity and mortality ⁶	Not confirmed, possible increased risk of in-hospital mortality ^{7,8}	Not confirmed, possible increased risk of hospitalization ⁹	Under investigation
Risk of reinfection	Neutralizing activity retained ¹⁰ , risk of reinfection remain similar ^{11,12}	Reduction in neutralizing activity reported. T cell response elicited by D614G prototype virus remains effective against B.1.351 ¹³⁻¹⁵	Moderate reduction in neutralizing activity reported ^{16,17}	Under investigation, possible modest reduction in neutralization activity (B.1.617.1) ⁴
Impacts on diagnostics	Limited impact – S gene target failure (SGTF; no impact on overall result from multiple target RT-PCR, No impact on Ag RDTs observed. ¹⁸	No impact on RT-PCR or Ag RDTs observed ¹⁶	None reported to date	None reported to date

**Generalized findings as compared to wildtype/non-VOC viruses. Based on emerging evidence, including non-peer-reviewed preprint articles and reports, all subject to ongoing investigation and revision.*

Further to our last detailed update published two weeks ago, new evidence is emerging that secondary attack rates for variant B.1.617.2 reported in the United Kingdom from 29 March to 28 April 2021 were higher than that of B.1.1.7, among travellers and non-travellers.¹⁹ Secondary attack rates for B.1.617.2 and B.1.1.7 were measured by the proportion of positive tests among contacts of confirmed or probable cases infected with variants.

A pre-print study of three outbreaks among kindergarten-aged children in Germany suggested that children aged 1 to 5 years who were infected with variant B.1.1.7 were as susceptible and infectious as adults infected with B.1.1.7 (measured by secondary attack rates) in both kindergarten (23% vs. 30%; $p=0.15$) and household (32% vs. 39%; $p=0.27$) settings.²⁰

A study of seven European countries assessing disease severity of cases reported from 13 September 2020 to 13 March 2021 ($n=23\,343$) reported that a significantly higher proportion of cases infected with one of the three VOCs: B.1.1.7, B.1.351 and P.1—were admitted to the hospital (11% for B.1.1.7/SGTF; 19% for B.1.351; 20% for P.1) compared to those infected with non-VOCs (7.5%, $p < 0.01$ for all VOCs). Similarly, a higher proportion of cases infected with these VOCs were admitted to the ICU (1.4% for B.1.1.7/SGTF, $p < 0.01$; 2.3% for B.1.351, $p < 0.01$; 2.1% for P.1, $p < 0.01$) compared to those infected with non-VOCs (0.6%).⁹

Table 4. Summary of vaccine performance against Variants of Concern (VOC) relative to previously circulating (non-VOC) variants

B.1.1.7	B.1.351	P.1	B.1.617
Efficacy/effectiveness against disease or infection			
Protection retained against disease	Reduced protection against disease, limited evidence	Protection likely against disease, very limited evidence on only one vaccine	Protection likely against disease (for B.1.617.2), very limited evidence on only two vaccines
Severe disease: No/minimal loss: Pfizer BioNTech-Comirnaty ²¹⁻²⁵	Severe disease: No/minimal loss: Janssen Ad26.COV 2.5, PfizerBioNTech-Comirnaty ^{23,37}	Symptomatic Disease: No/minimal loss: Sinovac-CoronaVac ^{40,41}	Symptomatic Disease: B.1.617.2: No/minimal loss:
Symptomatic Disease & Infection: No/minimal loss: AstraZeneca- Vaxzevria, Novavax-Covavax, Pfizer BioNTech-Comirnaty ⁶⁻¹⁵	Mild-moderate disease: Moderate loss: Janssen-Ad26.COV 2.5, Novavax-Covavax ^{37,38} Inconclusive/substantial loss, limited sample size: AstraZeneca-Vaxzevria ³⁹	Infection: No/minimal loss: Sinovac-CoronaVac ⁴¹	AstraZeneca- Vaxzevria after one dose and Pfizer BioNTech-Comirnaty after two doses ⁴²
Asymptomatic infection: No/minimal loss: Pfizer BioNTech-Comirnaty ^{22,36} Inconclusive/Moderate-substantial loss, limited sample size: AstraZeneca-Vaxzevria ²⁷	Infection: Moderate loss: Pfizer BioNTech-Comirnaty ²³ Asymptomatic infection: No evidence		Minimal/modest loss: AstraZeneca- Vaxzevria after two doses ⁴²
Neutralization			
No/minimal loss: Bharat-Covaxin, Gamaleya-Sputnik V, Moderna- mRNA-1273, Novavax-Covavax, Pfizer BioNTech-Comirnaty, BeijingCNBG-BBIBP-CorV, Sinovac-CoronaVac ⁴³⁻⁶⁴	Minimal/modest loss: Beijing CNBG-BBIBP-CorV, Sinovac-CoronaVac, Anhui ZL - Recombinant ⁶⁵⁻⁶⁷	No/minimal loss: AstraZeneca-Vaxzevria, Sinovac-CoronaVac ^{58,74}	B.1.617 (sublineage unspecified) Minimal/modest loss: Bharat-Covaxin ⁷⁷
Minimal/moderate loss: AstraZeneca-Vaxzevria ^{27,58}	Minimal to substantial loss: Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty ^{44,48,50-55,57-59,68-73} Moderate to substantial loss: AstraZeneca-Vaxzevria, Gamaleya-Sputnik V, Novavax-Covavax ^{50,60,70,70}	Minimal/moderate loss: Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty ^{44,45,55,57,58,64,75,76}	B.1.617.1: Minimal/modest loss: SII - Covishield ⁷⁸ Modest/moderate loss: Moderna- mRNA-1273, Pfizer BioNTech-Comirnaty ^{73,79,80} B.1.617.2, B.1.617.3: No sublineage-specific evidence

Further to our last update on vaccine performance against VOCs, new Phase III efficacy results from the United Kingdom have been made available and provide evidence that Novavax-Covavax is highly efficacious at preventing COVID-19 disease due to B.1.1.7. Efficacy against B.1.1.7 symptomatic disease ≥ 7 days after the second dose was 86.3% (95% CI: 71.3%-93.5%), similar to that against non-B.1.1.7 disease: 96.4% (95% CI: 73.8%-99.5%).²⁶

In addition, two new preprint studies (not yet peer-reviewed) estimated vaccine effectiveness (VE) of Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines against COVID-19 mortality and hospitalization among older adults in the United Kingdom. Both studies were conducted between December 2020 and April 2021 when B.1.1.7 accounted for the vast majority of sequenced viruses in the United Kingdom. The first study evaluated VE against mortality within 28 days of a positive PCR test among individuals ≥ 70 years who

developed symptomatic disease and is the first peer-reviewed publication to estimate the effectiveness of AstraZeneca-Vaxzevria against mortality. Results show a single dose of AstraZeneca-Vaxzevria offers levels of protection against mortality among people who develop disease (VE: 55%, 95% CI: 41-66%) similar to a single dose of Pfizer BioNTech-Comirnaty (VE: 44%, 95% CI: 3-53%). VE of two doses of Pfizer BioNTech-Comirnaty against death among people who develop disease was 69% (95% CI: 31-86%). Data were insufficient to estimate effectiveness of two doses of AstraZeneca-Vaxzevria. This study estimates the protection of vaccination against death (in addition to protection against symptomatic disease), and, taken together with VE estimates against symptomatic disease in the same age group, suggest approximately 80% protection of a single dose of either vaccine and approximately 97% protection for two doses of Pfizer BioNTech-Comirnaty against mortality in older adults.²⁴ A second study estimated overall VE against hospitalization ≥ 28 post first dose to be 73% (95% CI: 60-81%) for the AstraZeneca-Vaxzevria and 81% (95% CI: 76-85%) for Pfizer BioNTech-Comirnaty among individuals ≥ 80 years; VE against hospitalization ≥ 14 days post second dose of Pfizer BioNTech-Comirnaty was 93% (89-95%).²⁵ These studies provide real-world evidence that AstraZeneca-Vaxzevria and Pfizer BioNTech-Comirnaty vaccine provide good protection against severe disease in settings where B.1.1.7 are prevalent.

A test-negative, case-control pre-print study in Sao Paulo state, Brazil, among adults ≥ 70 years of age from mid-January through April 2021 found a VE of 41.6% (95% CI: 26.9-53.3%) against symptomatic COVID-19 ≥ 14 days after the second dose of Sinovac- CoronaVac⁴¹ during a period of widespread P.1 circulation (P.1 comprised 83% of genotyped isolates in March and April 2021). VE was reported as 49.4% (95% CI: 26.9-65.0%) at ≥ 21 days after the second dose. These findings are consistent with clinical trial results conducted in health workers in Brazil when P.1 was not yet widespread.⁷⁴

A new pre-print study from the United Kingdom suggested slightly lower effectiveness for Pfizer BioNTech-Comirnaty and AstraZeneca-Vaxzevria vaccines against symptomatic disease caused by B.1.617.2 compared to symptomatic disease caused by B.1.1.7. VE of two doses of Pfizer BioNTech-Comirnaty was 93.4% (95% CI: 90.4-95.5%) against B.1.1.7 and 87.9% (95% CI: 78.2-93.2%) against B.1.617.2. VE of two doses of AstraZeneca-Vaxzevria was 66.1% (95% CI: 54.0-75.0%) against B.1.1.7 and 59.8% (95% CI: 28.9-77.3%) against B.1.617.2.⁴² In a clinical trial conducted in the United Kingdom between June and December 2020, efficacy of two doses of AstraZeneca-Vaxzevria against symptomatic disease was 81.5% (67.9-89.4%) for non-B.1.1.7 lineages and 70.4% (43.6-84.5%) for B.1.1.7, a comparable result to that of the effectiveness study.²⁷ Differences in point estimates for efficacy and effectiveness for AstraZeneca-Vaxzevria were not statistically significant, and therefore should not be over-interpreted.

Recent studies provide evidence of some loss of neutralization capacity of COVID-19 vaccines against B.1.617.1. One study found a two-fold reduction in neutralization capacity against B.1.617.1 after two doses of SII - Covishield compared to the prototype B.1 lineage (n=21).⁷⁸ These findings excluded ten samples that did not show neutralizing antibody titer against B.1 nor B.1.617.1, and 12 samples that showed neutralizing antibody titer only against B.1. Another study found a seven-fold reduction in neutralization of B.1.617.1 among sera from vaccinees receiving two doses of Moderna- mRNA-1273 (n=15) or Pfizer BioNTech-Comirnaty (n=10); however, a majority of sera were still able to neutralize the variant.⁸⁰ Two additional studies provided further evidence of modest to moderate loss of neutralization by Pfizer BioNTech-Comirnaty and Moderna- mRNA-1273 vaccines against the pseudotype virus bearing B.1.617.1 spike mutations that are shared with B.1.617.3.^{73,79} Finally, a fifth study showed a two-fold loss of neutralization against B.1.617 for Bharat – Covaxin vaccine, a loss comparable to that seen with VOC 202012/01 (B.1.1.7); however, no information was available on the B.1.617 sublineages included in this study.⁷⁷ Taken together, these early studies suggest some loss of neutralization capacity against B.1.617; however, it is unclear whether this loss translates into decreased vaccine efficacy/effectiveness. Vaccine efficacy and real-world effectiveness evidence for B.1.617.1, B.1.617.2 or B.1.617.3 is limited.

Geographic distribution

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs has continued to increase (Figures 3 and 4, Annex 2). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities, sharing of sequencing data to publicly available platforms and sampling strategies between countries.

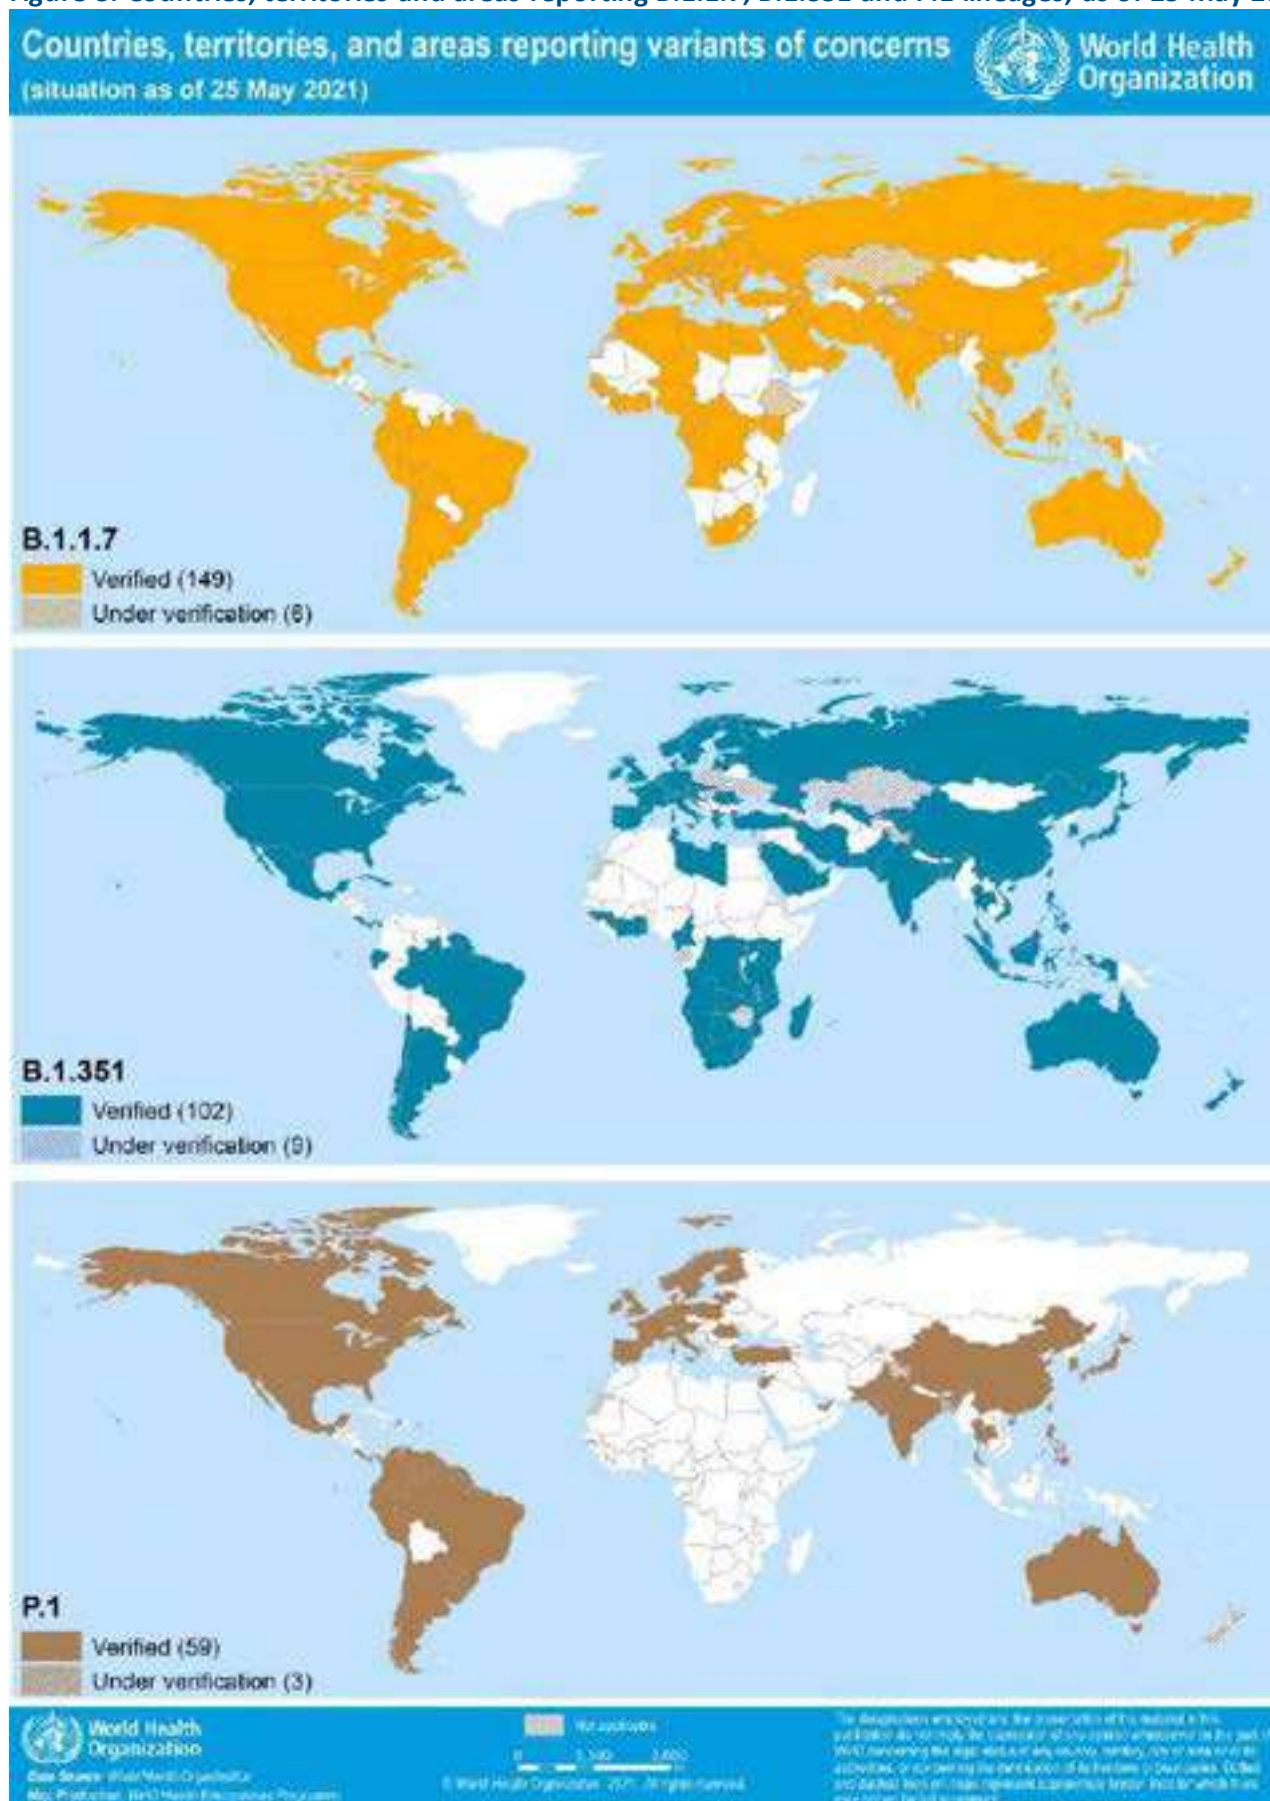

WHO recommendations

Virus evolution is expected, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods, such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the PHSM, including infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

WHO regional overviews

African Region

The African Region reported over 44 000 new cases and over 1000 new deaths, a 4% and a 2% increase respectively compared to the previous week. The incidences of cases and deaths remain at similar rates to the previous four weeks. The highest numbers of new cases were reported from South Africa (21 429 new cases; 36.1 new cases per 100 000 population; a 31% increase), Ethiopia (3069 new cases; 2.7 new cases per 100 000; a 15% decrease), and Kenya (2729 new cases; 5.1 new cases per 100 000; a 27% increase).

The highest numbers of new deaths were reported from South Africa (589 new deaths; 1.0 new deaths per 100 000 population; a 28% increase), Ethiopia (92 new deaths; 0.1 new deaths per 100 000; a 12% decrease), and Angola (60 new deaths; 0.2 new deaths per 100 000; a 140% increase).

Region of the Americas

The Region of the Americas reported over 1.2 million new cases and over 31 000 new deaths. Overall case and death incidence has remained stable in recent weeks; however, sizeable increases have been observed in several countries. The highest numbers of new cases were reported from Brazil (451 424 new cases; 212.4 new cases per 100 000; a 3% increase), Argentina (213 046 new cases; 471.4 new cases per 100 000; a 41% increase), and the United States of America (188 410 new cases; 56.9 new cases per 100 000; a 20% decrease).

The highest numbers of new deaths were reported from Brazil (13 681 new deaths; 6.4 new deaths per 100 000; similar to the previous week), the United States of America (4032 new deaths; 1.2 new deaths per 100 000; a 3% decrease), and Argentina (3538 new deaths; 7.8 new deaths per 100 000; a 19% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 215 000 new cases and over 4200 new deaths, a 2% and an 11% decrease respectively compared to the previous week. Overall case incidence has remained stable following sizeable increases observed in several countries in the region. Death incidence has decreased steeply for the past four weeks. The highest numbers of new cases were reported from the Islamic Republic of Iran (84 012 new cases; 100.0 new cases per 100 000; a 15% decrease), Iraq (27 232 new cases; 67.7 new cases per 100 000; a 4% decrease), and Pakistan (22 717 new cases; 10.3 new cases per 100 000; an 11% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1748 new deaths; 2.1 new deaths per 100 000; a 17% decrease), Pakistan (710 new deaths; 0.3 new deaths per 100 000; a 6% increase), and Tunisia (403 new deaths; 3.4 new deaths per 100 000; a 6% decrease).

European Region

The European Region reported just under 525 000 new cases and just under 13 000 new deaths, a 25% and a 21% decrease respectively compared to the previous week. A sharp downward trend in cases and deaths has been observed over the last five weeks. The highest numbers of new cases were reported from Turkey (71 786 new cases; 85.1 new cases per 100 000; a 21% decrease), the Russian Federation (61 260 new cases; 42.0 new cases per 100 000; a 2% increase), and Germany (55 524 new cases; 66.8 new cases per 100 000; a 24% decrease).

The highest numbers of new deaths were reported from the Russian Federation (2611 new deaths; 1.8 new deaths per 100 000; a 3% increase), Turkey (1534 new deaths; 1.8 new deaths per 100 000; a 14% decrease), and Ukraine (1293 new deaths; 3.0 new deaths per 100 000; a 23% decrease).

South-East Asia Region

The South-East Asia Region reported over 2 million new cases and over 32 000 new deaths, a 21% decrease and a 4% increase respectively compared to the previous week. While the overall incidence of cases continues to decrease (driven primarily by trends in India), death incidence continued to increase for a tenth consecutive week, and sizeable increases have been observed in other countries in the region. The highest numbers of new cases were reported from India (1 846 055 new cases; 133.8 new cases per 100 000; a 23% decrease), Nepal (57 939 new cases; 198.9 new cases per 100 000; a 6% decrease), and Indonesia (33 270 new cases; 12.2 new cases per 100 000; a 24% increase).

The highest numbers of new deaths were reported from India (28 982 new deaths; 2.1 new deaths per 100 000; a 4% increase), Nepal (1297 new deaths; 4.5 new deaths per 100 000; a 6% increase), and Indonesia (1238 new deaths; 0.5 new deaths per 100 000; a 10% increase).

Western Pacific Region

The Western Pacific Region reported over 131 000 new cases (similar to the previous week) and over 2100 new deaths (a 22% increase). The absolute numbers of cases and deaths remain the highest reported since the beginning of the pandemic. The highest numbers of new cases were reported from the Philippines (40 034 new cases; 36.5 new cases per 100 000; an 8% decrease), Malaysia (38 785 new cases; 119.8 new cases per 100 000; a 32% increase), and Japan (36 286 new cases; 28.7 new cases per 100 000; a 19% decrease).

The highest numbers of new deaths were reported from the Philippines (895 new deaths; 0.8 new deaths per 100 000; a 14% increase), Japan (773 new deaths; 0.6 new deaths per 100 000; a 21% increase), and Malaysia (333 new deaths; 1.0 new deaths per 100 000; a 59% increase).

Key weekly updates

WHO Director-General's key messages

[Opening remarks at the World Health Assembly – 24 May 2021:](#)

- Although we have lost so many health and care workers already, we will lose many more as long as the pandemic rages. Almost 18 months into the defining health crisis of our age, the world remains in a very fragile and dangerous situation.
- No country should assume it is out of the woods, no matter its vaccination rate.
- WHO's Strategic Preparedness and Response Plan sets out the ten pillars that every country must apply in a tailored and dynamic way to reduce exposure, prevent infections, limit the spread, and save lives. Every country can do more:
 - Increase surveillance, testing, sequencing, and sharing information;
 - Surge supplies needed to protect health workers;
 - Fight misinformation and disinformation;
 - Empower people and communities to play their part;
 - Support businesses and workplaces to take steps to open up safely, where appropriate;
 - Implement national vaccination strategies, vaccinate those most at risk, and donate vaccines to COVAX.
- We must be very clear: the pandemic is not over, and it will not be over until and unless transmission is controlled in every last country.

Additional updates

On 21 May, [World leaders met at the Global Health Summit](#), co-hosted by the European Commission and Italy as part of its G20 presidency, to [adopt an agenda to overcome the COVID-19 pandemic](#), and develop and endorse a [Rome Declaration](#) of Principles.

*Newly reported in this update.

“●” indicates that information for this variant was received by WHO from official sources.

“○” indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

Variant B.1.617.1 for Angola was excluded this week based on further information received.

**Includes countries/territories/areas reporting the detection of VOCs among travelers (e.g., imported cases detected at points of entry), or local cases (detected in the community). Efforts are ongoing to differentiate these in future reports.

**See also [Annex 3: Data, table and figure notes](#)

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 758 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.

- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 16 May 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: Update on SARS-CoV-2 Variants of Interest \(VOIs\) and Variants of Concern \(VOCs\)](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Globally, in the past week, the number of new cases and deaths continued to decrease with just over 4.8 million new cases and just under 86 000 new deaths reported; a 12% and 5% decrease respectively compared to the previous week (Figure 1). Despite a declining trend over the past three weeks, the incidence of cases remains at some of the highest levels since the start of the pandemic. All regions reported a decline in new cases this week apart from the Western Pacific Region, where the incidence of new cases was similar to the previous week (Table 1). The European Region reported the largest decline in new cases this week, followed by the Eastern Mediterranean. These regions also reported the largest decline in new deaths over the past week. South-East Asia and Western Pacific regions reported a similar number of new deaths as the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 16 May 2021**

**See [Annex 3: Data, table and figure notes](#)

The highest numbers of new cases were reported from India (2 387 663 new cases; 13% decrease), Brazil (437 076 new cases; 3% increase), the United States of America (235 638 new cases; 21% decrease), Argentina (151 332 new cases; 8% increase), and Colombia (115 834 new cases; 6% increase).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 16 May 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 201 726 (25%)	-3%	64 757 485 (40%)	31 439 (37%)	-7%	1 583 343 (47%)
Europe	684 903 (14%)	-26%	53 565 774 (33%)	16 255 (19%)	-16%	1 121 477 (33%)

Figure 2. COVID-19 cases per 100 000 population reported by countries, territories and areas, 10 May – 16 May 2021**

**See Annex 3: Data, table and figure notes

Special Focus: Update on SARS-CoV-2 Variants of Interest (VOIs) and Variants of Concern (VOCs)

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they result in changes in public health and social measures (PHSM) implementation by national health authorities. Systems have been established to detect “signals” of potential variants of concern (VOCs) or variants of interest (VOIs) and assess these based on the risk posed to global public health (see also [working definitions](#)). National authorities may choose to designate other variants of local interest/concern. Detailed information on currently circulating VOCs and VOIs is available in previously published editions of the [Weekly Epidemiological Update](#). Here we provide a brief update on the geographical distribution of the four VOCs as of 18 May 2021, as well as an update on detected VOIs (Table 2).

Table 2: SARS-CoV-2 Variants of Concern and Variants of Interest, as of 18 May 2021

PANGO lineage Nextstrain clade GISAID clade	Alternate name	First detected in	Earliest samples	Characteristic spike mutations
Variants of Concern (VOCs)				
B.1.1.7 20I/501Y.V1 GR/501Y.V1	VOC 202012/01	United Kingdom	Sep 2020	69/70del, 144del, N501Y, A570D, D614G, P681H, T716I, S982A, D1118H

B.1.616 - GH	-	France	Feb 2021	H66D, G142V, 144del, D215G, V483A, D614G, H655Y, G669S, Q949R, N1187D

* B.1.617 lineage is divided in three sublineages (B.1.617.1, B.1.617.2 and B.1.617.3). Findings for sublineages B.1.617.1 and B.1.617.2 were mainly used to declare B.1.617 a global VOC. Once more information becomes available, specific sublineages may be declared as a global VOI/VOC.

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs and VOIs has continued to increase (Figures 3 - 6, Annex 2). This distribution should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and sampling strategies between countries.

Figure 3. Countries, territories and areas reporting B.1.1.7 lineage, as of 18 May 2021

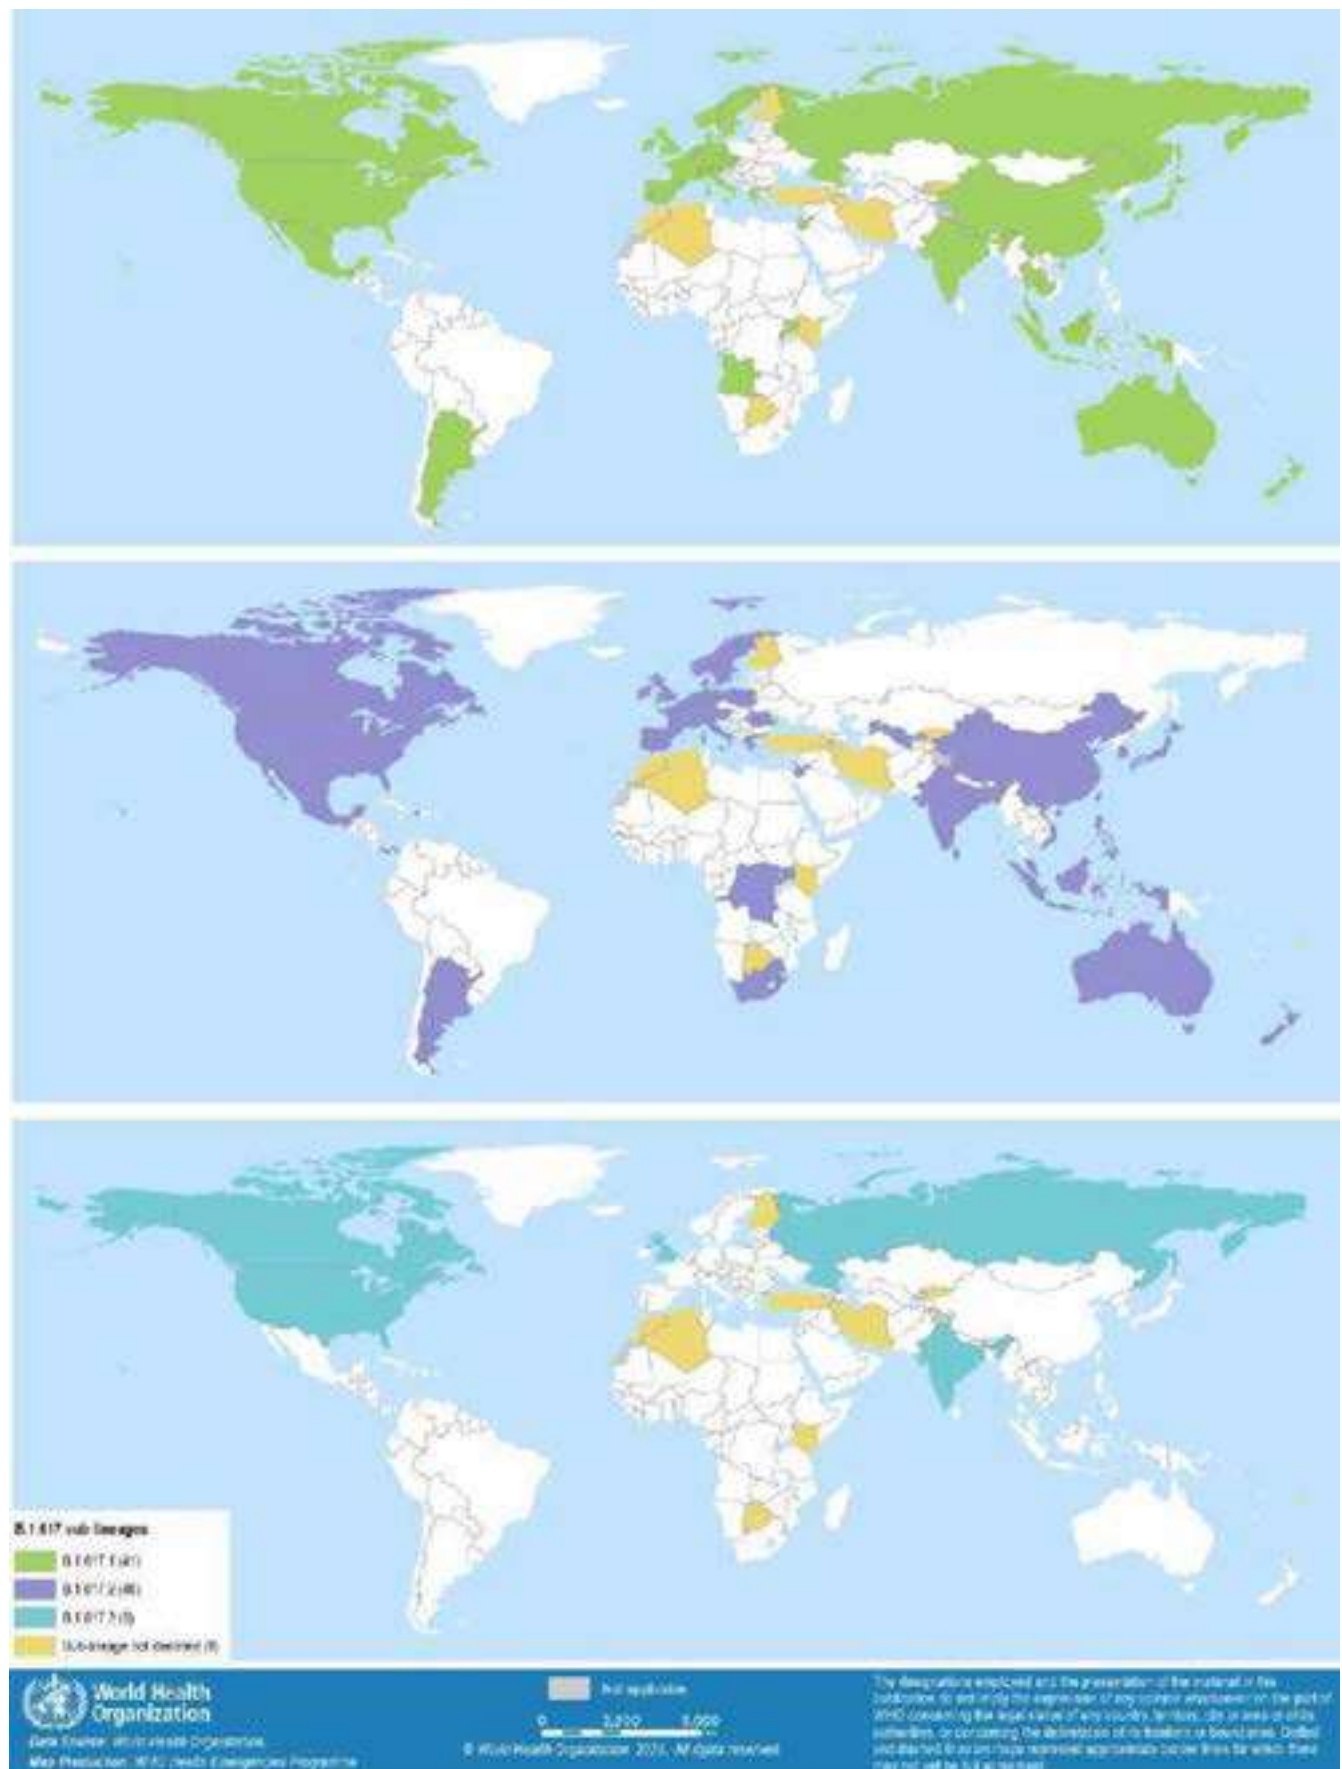

Figure 4. Countries, territories and areas reporting B.1.351 lineage, as of 18 May 2021

Figure 5. Countries, territories and areas reporting P.1 lineage, as of 18 May 2021

Figure 6. Countries, territories and areas reporting B.1.617.1, B.1.617.2 and B.1.617.3 sublineages, or B.1.617 with an unspecified sublineage, as of 18 May 2021*

*Countries/territories/areas listed in this figure include both official and unofficial reports of B.1.617 detection pending verification. Please see [Annex 2](#) for details.

WHO recommendations

Virus evolution is expected, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the PHSM, including infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

WHO regional overviews

African Region

The African Region reported over 40 000 new cases and over 900 new deaths, a 4% and a 9% decrease respectively compared to the previous week. Case incidence continued to decrease for a fourth consecutive week while the number of deaths has reflected similar trends during this period. The highest numbers of new cases were reported from South Africa (16 326 new cases; 27.5 new cases per 100 000 population; a 36% increase), Botswana (3745 new cases; 159.3 new cases per 100 000; a 153% increase), and Ethiopia (3615 new cases; 3.1 new cases per 100 000; a 13% decrease). Cases in South Africa comprised 41% of cases reported in the Region.

The highest numbers of new deaths were reported from South Africa (459 new deaths; 0.8 new deaths per 100 000 population; a 44% increase), Kenya (118 new deaths; 0.2 new deaths per 100 000; a 15% decrease), and Ethiopia (105 new deaths; 0.1 new deaths per 100 000; a 35% decrease).

Region of the Americas

The Region of the Americas reported over 1.2 million new cases and over 31 000 new deaths, a 3% and a 7% decrease respectively compared to the previous week. The number of cases decreased for a fourth consecutive week, and the number of deaths decreased for a second consecutive week. The highest numbers of new cases were reported from Brazil (437 076 new cases; 205.6 new cases per 100 000; a 3% increase), the United States of America (235 638 new cases; 71.2 new cases per 100 000; a 21% decrease), and Argentina (151 332 new cases; 334.8 new cases per 100 000; an 8% increase).

The highest numbers of new deaths were reported from Brazil (13 514 new deaths; 6.4 new deaths per 100 000; a 12% decrease), the United States of America (4143 new deaths; 1.3 new deaths per 100 000; a 12% decrease), and Colombia (3383 new deaths; 6.6 new deaths per 100 000; an 8% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 220 000 new cases and over 4700 new deaths, a 22% and a 16% decrease respectively compared to the previous week. Case and death incidences have decreased steeply for the past four and two weeks respectively. The highest numbers of new cases were reported from the Islamic Republic of Iran (99 205 new cases; 118.1 new cases per 100 000; a 20% decrease), Iraq (28 359 new cases; 70.5 new cases per 100 000; a 26% decrease), and Pakistan (20 511 new cases; 9.3 new cases per 100 000; a 29% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (2109 new deaths; 2.5 new deaths per 100 000; a 13% decrease), Pakistan (670 new deaths; 0.3 new deaths per 100 000; a 20% decrease), and Tunisia (429 new deaths; 3.6 new deaths per 100 000; a 21% decrease).

European Region

The European Region reported just under 685 000 new cases and over 16 000 new deaths, a 26% and a 16% decrease respectively compared to the previous week. The number new of cases and deaths continued their downward trend for a sixth and fifth consecutive week respectively. The highest numbers of new cases were reported from France (93 546 new cases; 143.8 new cases per 100 000; a 24% decrease), Turkey (90 721 new cases; 107.6 new cases per 100 000; a 46% decrease), and Germany (73 105 new cases; 87.9 new cases per 100 000; a 29% decrease).

The highest numbers of new deaths were reported from Russian Federation (2545 new deaths; 1.7 new deaths per 100 000; a 3% increase), Turkey (1791 new deaths; 2.1 new deaths per 100 000; a 20% decrease), and Ukraine (1682 new deaths; 3.8 new deaths per 100 000; a 6% decrease).

South-East Asia Region

The South-East Asia Region reported over 2.5 million new cases and over 30 000 new deaths, a 12% decrease and a 7% increase respectively compared to the previous week. Case incidence decreased after nine consecutive weeks of increases, although the absolute number remains at its highest level since the beginning of the pandemic. Death incidence continued to increase for a ninth consecutive week. The highest numbers of new cases were reported from India (2 387 663 new cases; 173.0 new cases per 100 000; a 13% decrease), Nepal (61 814 new cases; 212.2 new cases per 100 000; an 8% increase), and Indonesia (26 908 new cases; 9.8 new cases per 100 000; a 27% decrease).

The highest numbers of new deaths were reported from India (27 922 new deaths; 2.0 new deaths per 100 000; a 4% increase), Nepal (1224 new deaths; 4.2 new deaths per 100 000; a 266% increase), and Indonesia (1125 new deaths; 0.4 new deaths per 100 000; a 5% decrease).

Western Pacific Region

The Western Pacific Region reported over 132 000 new cases and over 1700 new deaths, both increasing by 4% compared to the previous week. Both weekly case and death incidences were the highest reported in the Region since the beginning of the pandemic. The highest numbers of new cases were reported from Japan (44 961 new cases; 35.5 new cases per 100 000; a 26% increase), the Philippines (43 339 new cases; 39.5 new cases per 100 000; a 10% decrease), and Malaysia (29 386 new cases; 90.8 new cases per 100 000; a 16% increase). These three countries comprised 89% of all cases reported in the Region in the past week.

The highest numbers of new deaths were reported from the Philippines (782 new deaths; 0.7 new deaths per 100 000; a 15% decrease), Japan (640 new deaths; 0.5 new deaths per 100 000; a 21% increase), and Malaysia (209 new deaths; 0.6 new deaths per 100 000; a 54% increase).

Key weekly updates

WHO Director-General's key messages

[Opening remarks at the media briefing on COVID-19](#) – 17 May 2021:

- WHO Director-General Dr Tedros urged Member States to continue donating vaccines to COVAX in an effort to increase vaccine-supply to low-income countries, which are presently receiving only about 0.3% of all supply. UNICEF Executive Director Henrietta Fore also called vaccine equity, warning of a huge shortfall in the vaccine supply to COVAX, in a [statement released by UNICEF](#).
- This week marks UN Global Road Safety, with the aim to lower speeds to significantly reduce the risk of death and injury. Although increased public health and social measures during the pandemic has meant more people have been working from home and overall there has been less road traffic, the number of traffic-related deaths did not decrease to the same degree.

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 758 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.

- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 9 May 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: SARS-CoV-2 variants](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

The number of new COVID-19 cases and deaths globally decreased slightly this week, with over 5.5 million cases and over 90 000 deaths (Figure 1). Case and death incidence, however, remains at the highest level since the beginning of the pandemic. New weekly cases decreased in the regions of Europe and Eastern Mediterranean, while the South-East Asia Region continued an upward trajectory for 9 weeks and reported a further 6% increase last week (Table 1). Death incidence increased in the South-East Asia and Western Pacific regions. While India continues to account for 95% of cases and 93% of deaths in the South-East Asia Region, as well as 50% of global cases and 30% of global deaths, worrying trends have been observed in neighbouring countries. In all WHO Regions there are countries which have been showing a sustained upward trend in cases and deaths over several weeks.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 9 May 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from India (2 738 957 new cases; 5% increase), Brazil (423 438 new cases; similar to previous week), the United States of America (334 784 new cases; 3% decrease), Turkey (166 733 new cases; 35% decrease), and Argentina (140 771 new cases; 8% decrease).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 9 May 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 272 491 (23%)	-4%	63 554 005 (40%)	33 879 (38%)	-8%	1 551 860 (47%)
Europe	919 119 (17%)	-23%	52 871 662 (34%)	19 056 (21%)	-18%	1 104 629 (34%)
South-East Asia	2 877 410 (52%)	6%	25 552 640 (16%)	28 977 (32%)	15%	309 197 (9%)
Eastern Mediterranean	280 853 (5%)	-13%	9 428 375 (6%)	5 605 (6%)	-13%	189 052 (6%)
Africa	40 656 (1%)	-5%	3 357 846 (2%)	1 034 (1%)	3%	83 904 (3%)
Western Pacific	127 073 (2%)	-4%	2 597 134 (2%)	1 691 (2%)	34%	39 179 (1%)
Global	5 517 602 (100%)	-4%	157 362 408 (100%)	90 242 (100%)	-4%	3 277 834 (100%)

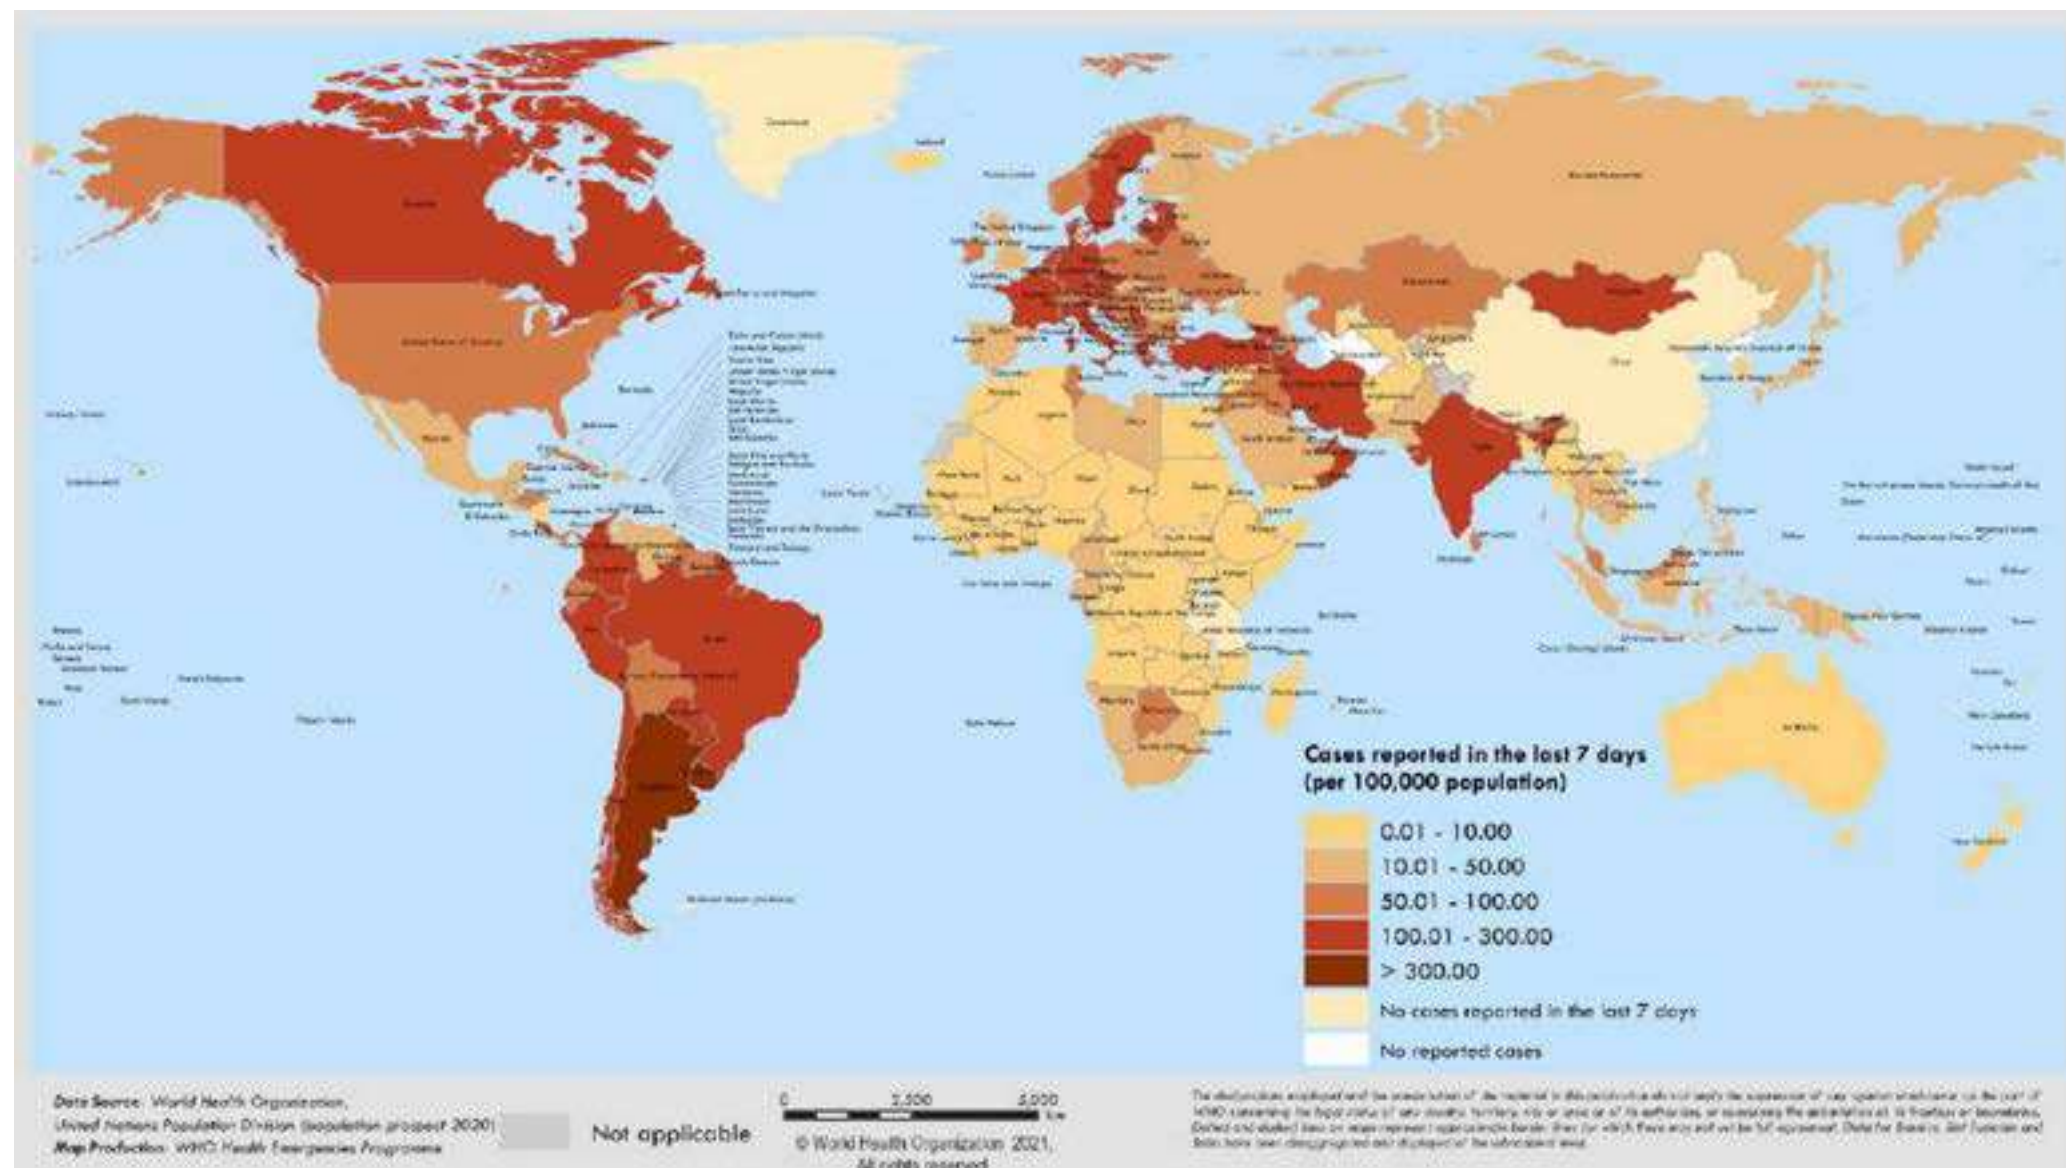

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

Special Focus: Update on SARS-CoV-2 variants

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they result in changes in public health and social measures (PHSM) implementation by national health authorities. Systems have been established to detect “signals” of potential variants of concern (VOCs) or variants of interest (VOIs) and assess these based on the risk posed to global public health (see also [working definitions](#)). National authorities may choose to designate other variants of local interest/concern. Detailed information on currently circulating VOCs and VOIs is available in previously published editions of the [Weekly Epidemiological Update](#). Here we provide information on a newly designated VOC within lineage B.1.617, and provide an update on the geographical distribution, and emerging evidence surrounding phenotypic characteristics of all designated VOIs and VOCs.

Newly designated VOC within lineage B.1.617

In consultation with the WHO SARS-CoV-2 Virus Evolution Working Group, WHO has determined that viruses within the lineage B.1.617 have been characterized as a VOC. B.1.617 contains three sub-lineages (Table 2), which differ by few but potentially relevant mutations in the spike protein as well as prevalence of detection globally. As of 11 May, over 4500 sequences have been uploaded to GISAID and assigned to B.1.617 from 44 countries in all six WHO regions, and WHO has received reports of detections from five additional countries (Figure 3). Though there may be important differences among the three sublineages, currently available evidence is too limited for VOI/VOC characterization by sublineage. Future delineation of sublineages as VOIs/VOCs may be possible as our understanding by sublineage and relative importance of their epidemiology increases. At the present time, WHO has designated B.1.617 as a VOC based on early evidence of phenotypic impacts compared to other circulating virus variants, namely:

- B.1.617 sublineages appear to have higher rates of transmission, including observed rapid increases in prevalence in multiple countries (moderate evidence available for B.1.617.1 and B.1.617.2), and
- Preliminary evidence suggests potential reduced effectiveness of Bamlanivimab, a monoclonal antibody used for COVID-19 treatment, and potentially slightly reduced susceptibility to neutralisation antibodies (limited evidence available for B.1.617.1).

Table 2: Overview of B.1.617 sublineages, as of 11 May 2021

Sublineage	B.1.617.1	B.1.617.2	B.1.617.3
Sequences in GISAID	2001	2507	67
Number of countries reporting detections	34 (in 6 WHO regions)	31 (in 5 WHO regions)	4 (in 3 WHO regions)
Number of lineage-defining spike mutations*	7	8	6
Characteristic spike mutations*	G142D, E154K, L452R, E484Q, D614G, P681R, Q1071H	T19R, G142D, del157/158, L452R, T478K, D614G, P681R, D950N	T19R, L452R, E484Q, D614G, P681R, D950N

*Mutations found in >60% of sequences

Figure 3. Countries, territories and areas with B.1.617.1, B.1.617.2 or B.1.617.3 sequences uploaded to GISAID and/or reported to WHO as of 11 May 2021*

* Unverified detections based primarily on GISAID, subject to change as WHO validates detection with Member States.

Viruses in the B.1.617 lineage were first reported in India in October 2020. The resurgence in COVID-19 cases and deaths in India has raised questions on the potential role of B.1.617 and other variants (e.g., B.1.1.7) in circulation. A recent risk assessment of the situation in India conducted by WHO found that resurgence and acceleration of COVID-19 transmission in India had several potential contributing factors, including increase in the proportion of cases of SARS-CoV-2 variants with potentially increased transmissibility; several religious and political mass gathering events which increased social mixing; and, under use of and reduced adherence to public health and social measures (PHSM). The exact contributions of these each of these factors on increased transmission in India are not well understood.

Approximately 0.1% of positive samples in India have been sequenced and uploaded to GISAID to identify SARS-CoV-2 variants. The prevalence of several VOCs including B.1.1.7 and B.1.612 sublineages increased concurrent to the surge in COVID-19 cases reported in India. While B.1.1.7 and B.1.612.1 variants have begun to wane in recent weeks, a marked increase in the proportion of viruses sequenced as B.1.612.2 has been observed over the same period. Since the identification of these variants through late April 2021, B.1.617.1 and B.1.617.2 accounted for 21% and 7% of sequenced samples from India, respectively.^a

Preliminary analyses conducted by WHO using sequences submitted to GISAID suggests that B.1.617.1 and B.1.617.2 have a substantially higher growth rate than other circulating variants in India, suggesting potential increased transmissibility compared. Too few sequences of B.1.617.3 have been detected to date to assess its relative transmissibility.

Other studies suggest that the case numbers increased more rapidly during the most recent surge when variants B.1.1.7 and B.1.617 were circulating, compared to the first surge (June to October 2020).^b A structural analysis of B.1.617 receptor binding domain (RBD) mutations (L452R and E484Q, along with P681R in the furin cleavage site) suggest that mutations in these variants may result in increased ACE2 binding and rate of S1-S2 cleavage resulting in better transmissibility, and possibly capacity to escape binding and neutralization by some monoclonal antibodies.^c In a preliminary study on hamsters, infection with B.1.617.1 resulted in increased body weight loss, higher viral load in lungs and pronounced lung lesions as compared to B.1 variants (D614G).^d

Potential impacts of B.1.617 lineage on effectiveness of vaccines or therapeutics, or reinfection risks, remain uncertain. Preliminary laboratory studies awaiting peer review suggest a limited reduction in neutralisation by antibodies; however, real-world impacts may be limited.^e One study found a seven-fold reduction in neutralization effectiveness against B.1.617.1 of antibodies generated by vaccination with Moderna - mRNA-1273 and Pfizer BioNTech-Comirnaty vaccines.^f A second study also found a reduction in neutralization against virus carrying the E484Q mutation (contained in B.1.617.1 and B.1.617.3) for Pfizer BioNTech - Comirnaty vaccine, similar to that found with the E484K mutation.^g A third study reviewing a limited sample of convalescent sera of COVID-19 cases (n=17) and sera from recipients of the Bharat - Covaxin vaccine (n=23) concluded that most neutralizing activity against B.1.617 was retained.^e A fourth study reported an approximately three-fold decrease in neutralization activity by plasma from recipients of Pfizer BioNTech - Comirnaty vaccine (n=15) against B.1.617, and a limited two-fold decrease by convalescent sera from cases with severe COVID-19 (n=15). The same study showed that B.1.617.1 (with additional spike mutations R21T, and Q218H) mediates increased entry into certain human and intestinal cell lines, and was resistant to the monoclonal antibody Bamlanivimab; however, it was efficiently inhibited by Imdevimab and by a cocktail of Casirivimab and Imdevimab.^e

Outside of India, the United Kingdom has reported the largest number of cases sequenced as B.1.617 sub-lineages, and recently designated B.1.617.2 as a national variant of concern. This follows a recent steep increase in the number of cases sequenced as B.1.617 sublineages, and a national assessment that characterized B.1.617.2 as at least equivalent in terms of transmissibility as VOC B.1.1.7; however, they noted insufficient data to assess the potential for immune escape.^h As of 5 May, the United Kingdom has reported 520 genomically confirmed B.1.617.2 cases (of which approximately two-thirds were domestically acquired), 261 confirmed B.1.617 cases (without further delineation), and nine confirmed B.1.617.3 cases.ⁱ

Further robust studies into the phenotypic impacts of these variants, including impacts on epidemiological characteristics (transmissibility, severity, re-infection risk, etc.) and impact on countermeasures, are urgently needed.

Other VOCs

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs and VOIs has continued to increase. Since our last update on 4 May, VOC 202012/01 has been detected in seven additional countries, variant 501Y.V2 in five additional countries, and variant P.1 in four additional countries. As of 11 May, a total 149 countries have reported VOC 202012/01 (Figure 4), 102 countries variant 501Y.V2 (Figure 5), and 60 countries variant P.1 (Figure 6) – see also Annex 2. The information presented here should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and prioritization of samples for sequencing between countries.

Table 3: SARS-CoV-2 Variants of Concern and Variants of Interest, as of 11 May 2021

Since the update on 27 April, two studies from Israel and another from Qatar offer further evidence that Pfizer BioNTech-Comirnaty vaccine provides similar protection against B.1.1.7 disease as that reported in clinical trials.⁴⁷ Both studies from Israel (one published and one preprint) used national surveillance data and found high vaccine effectiveness after the second dose. The published study estimated a vaccine effectiveness of 98.1% (95% CI: 97.6-98.5), 98.0% (97.7-98.3), 97.7% (97.5-97.9), 96.5% (96.3-96.8), and 93.8% (93.3-94.2) against death, hospitalization, symptomatic disease, infection, and asymptomatic infection ≥ 14 days post second dose, respectively, in a setting where B.1.1.7 accounted for 95% of documented SARS-CoV-2 cases.² The preprint from Israel reported similar findings.¹

In addition, the study from Qatar reports effectiveness of the vaccine to be 89.5% (95% CI: 85.9-92.3) against documented B.1.1.7 infection and 100% (95% CI: 81.7-100.0) against documented B.1.1.7 severe disease ≥ 14 days post second dose.³ The study also evaluated effectiveness of the Pfizer BioNTech-Comirnaty vaccine against B.1351-specific disease, finding somewhat reduced effectiveness of 75.0% (70.5-78.9%) against B.1.351 infection ≥ 14 days post second dose. However, effectiveness against B.1.351 severe disease ≥ 14 days post second dose was retained: 100% (73.7-100.0).³

A study from the United States of America conducted during a period when B.1.1.7 was circulating found that the Janssen - Ad26.COV 2.5 vaccine was 76.7% (95%CI: 30.3-95.3) effective against SARS-CoV-2 infection, similar to clinical trial efficacy findings conducted in a non-B.1.1.7 setting.⁴⁷ While this estimate is an average estimate across all circulating viruses during the study, B.1.1.7 was the most predominant variant in the region represented by the vast majority of participants (B.1.1.7 ranged from ~25-70% of sequenced viruses reported by the US Centers for Disease Control and Prevention during the study period in this region).⁴⁸

WHO recommendations

Virus evolution is an expected phenomenon, and the more SARS-CoV-2 circulates, the more opportunities it has to evolve. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the PHSM, including infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

WHO regional overviews

African Region

The African Region reported over 40 000 new cases and over 1000 new deaths, a 5% decrease and 3% increase respectively compared to the previous week. This follows a long-term downward trend in case and death incidence; however, this trend may soon reverse with cases and deaths beginning to climb again in some countries. The highest numbers of new cases were reported from South Africa (11 975 new cases; 20.2 new cases per 100 000 population; a 41% increase), Ethiopia (4155 new cases; 3.6 new cases per 100 000; a 42% decrease), and Cameroon (4126 new cases; 15.5 new cases per 100 000; a 10% decrease).

The highest numbers of new deaths were reported from South Africa (318 new deaths; 0.5 new deaths per 100 000 population; a 13% increase), Ethiopia (162 new deaths; 0.1 new deaths per 100 000; a 9% decrease), and Kenya (139 new deaths; 0.3 new deaths per 100 000; a 1% decrease).

Region of the Americas

The Americas reported over 1.2 million new cases and 33 000 new deaths, decreasing by 4% and 8% respectively compared to the previous week. This is the third consecutive week of decreasing case incidence across the region; however, cases and deaths continue to climb in some countries. The highest numbers of new cases were reported from Brazil (423 438 new cases; 199.2 new cases per 100 000; similar to previous week), the United States of America (334 784 new cases; 101.1 new cases per 100 000; a 3% decrease), and Argentina (140 771 new cases; 311.5 new cases per 100 000; an 8% decrease).

The highest numbers of new deaths were reported from Brazil (15 333 new deaths; 7.2 new deaths per 100 000; a 12% decrease), the United States of America (4940 new deaths; 1.5 new deaths per 100 000; a 4% increase), and Colombia (3147 new deaths; 6.2 new deaths per 100 000; a 4% decrease).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 280 000 new cases and over 5600 new deaths, both rates decreasing by 13% compared to the previous week. This is the first week a marked decrease in reported deaths has been reported following 11 weeks of rising numbers. The highest numbers of new cases were reported from the Islamic Republic of Iran (124 513 new cases; 148.2 new cases per 100 000; a 10% decrease), Iraq (38 192 new cases; 95.0 new cases per 100 000; a 15% decrease), and Pakistan (28 721 new cases; 13.0 new cases per 100 000; a 19% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (2434 new deaths; 2.9 new deaths per 100 000; an 18% decrease), Pakistan (840 new deaths; 0.4 new deaths per 100 000; a 12% decrease), and Tunisia (542 new deaths; 4.6 new deaths per 100 000; a 6% decrease).

European Region

The European Region reported over 897 000 new cases and just under 19 000 new deaths, a 25% and an 18% decrease respectively compared to the previous week. Cases and deaths in the region have been decreasing for the past month. The highest numbers of new cases were reported from Turkey (166 733 new cases; 197.7 new cases per 100 000; a 35% decrease), France (122 487 new cases; 188.3 new cases per 100 000; a 26% decrease), and Germany (103 507 new cases; 124.5 new cases per 100 000; a 20% decrease).

The highest numbers of new deaths were reported from Russian Federation (2464 new deaths; 1.7 new deaths per 100 000; a 6% decrease), Turkey (2242 new deaths; 2.7 new deaths per 100 000; a 10% decrease), and Poland (1944 new deaths; 5.1 new deaths per 100 000; a 27% decrease).

South-East Asia Region

The South-East Asia Region reported over 2.8 million new cases and just under 29 000 new deaths, a 6% and a 15% increase respectively compared to the previous week. This marks the ninth consecutive week the incidences of cases and deaths have been increasing in the region. The highest numbers of new cases were reported from India (2 738 957 new cases; 198.5 new cases per 100 000; a 5% increase), Nepal (56 997 new cases; 195.6 new cases per 100 000; a 79% increase), and Indonesia (36 882 new cases; 13.5 new cases per 100 000; a 2% increase).

The highest numbers of new deaths were reported from India (26 820 new deaths; 1.9 new deaths per 100 000; a 15% increase), Indonesia (1190 new deaths; 0.4 new deaths per 100 000; a 3% increase), and Bangladesh (368 new deaths; 0.2 new deaths per 100 000; a 34% decrease).

Western Pacific Region

The Western Pacific Region reported over 127 000 new cases and just under 1700 new deaths, a 4% decrease and a 34% increase respectively compared to the previous week. The highest numbers of new cases were reported from the Philippines (48 197 new cases; 44.0 new cases per 100 000; a 16% decrease), Japan (35 802 new cases; 28.3 new cases per 100 000; a 2% increase), and Malaysia (25 350 new cases; 78.3 new cases per 100 000; a 19% increase).

The highest numbers of new deaths were reported from the Philippines (915 new deaths; 0.8 new deaths per 100 000; a 35% increase), Japan (527 new deaths; 0.4 new deaths per 100 000; a 38% increase), and Malaysia (136 new deaths; 0.4 new deaths per 100 000; a 43% increase).

Key weekly updates

WHO Director-General's key messages

[Opening remarks at the media briefing on COVID-19](#) – 7 May 2021:

- The announcement on 5 May by the United States of America that it will [support a temporary waiver of intellectual property protections for COVID-19 vaccines](#) is a significant statement of solidarity and support for vaccine equity.
- On 7 May, [WHO listed Beijing CNBG \(Sinopharm\) - BBIBP-CorV COVID-19 vaccine for emergency use](#), making it the sixth vaccine to receive WHO validation for safety, efficacy and quality. The Strategic Advisory Group of Experts on Immunization (SAGE) has also reviewed the available data, and recommends the vaccine for adults 18 years and older, with a two-dose schedule.
- The WHO Director-General announced the establishment of the [WHO Council on the Economics of Health for All](#) to identify new ways to shape the global economy, and to build societies that are healthy, inclusive, equitable and sustainable.

Updates and publications

- [WHO, Germany launch new global hub for pandemic and epidemic intelligence](#)
- [Scientific Brief on COVID-19 natural immunity](#)
- [WHO's work in health emergencies – Strengthening preparedness for health emergencies: implementation of the International Health Regulations \(2005\)](#)
- [Estimating COVID-19 vaccine effectiveness against severe acute respiratory infections \(SARI\) hospitalizations associated with laboratory-confirmed SARS-CoV-2: an evaluation using the test-negative design](#)
- [The Partnership for Healthy Cities supports COVID-19 Vaccine Outreach in 18 Cities](#)
- [Joint Statement on transparency and data integrity International Coalition of Medicines Regulatory Authorities \(ICMRA\) and WHO](#)
- [WHO calls for better hand hygiene and other infection control practices](#)
- [COVID-19 home care bundle for health care workers](#)
- [COVID-19 considerations for tuberculosis \(TB\) care](#)

Technical guidance and other resources

- [Technical guidance](#)
- [WHO Coronavirus Disease \(COVID-19\) Dashboard](#)
- [Weekly COVID-19 Operational Updates](#)
- [WHO COVID-19 case definitions](#)
- [COVID-19 Supply Chain Inter-Agency Coordination Cell Weekly Situational Update](#)

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 746 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.

- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 2 May 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: World Hand Hygiene Day, 5 May 2021](#)
- [Special focus: WHO partnership with SeroTracker — synthesizing “real-time” seroprevalence data to support global pandemic response](#)
- [Special focus: SARS-CoV-2 variants](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

For the second successive week, the number of COVID-19 cases globally remains at the highest levels since the beginning of the pandemic with over 5.7 million new weekly cases, following nine consecutive weeks of increases (Figure 1). New deaths continue to increase for the seventh consecutive week, with over 93 000 deaths. The South-East Asia Region continues to report marked increases in both case and death incidences (Table 1). India accounts for over 90% of both cases and deaths in the region, as well as 46% of global cases and 25% of global deaths reported in the past week. Case incidence in the regions of Europe, Eastern Mediterranean, Africa and the Americas decreased, while rates in the Western Pacific Region were comparable to the previous week. The number of deaths decreased in Europe, Africa and the Western Pacific region, while slight increases were reported in the Americas and Eastern Mediterranean regions.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 2 May 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from India (2 597 285 new cases; 20% increase), Brazil (421 933 new cases; 4% increase), the United States of America (345 692 new cases; 15% decrease), Turkey (257 992 new cases; 32% decrease), and France (163 666 new cases; 23% decrease).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 2 May 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 330 513 (23%)	-5%	62 281 517 (41%)	36 715 (39%)	1%	1 517 981 (48%)
Europe	1 166 859 (20%)	-22%	51 920 795 (34%)	22 819 (24%)	-12%	1 084 814 (34%)
South-East Asia	2 709 582 (47%)	19%	22 675 230 (15%)	25 262 (27%)	48%	280 220 (9%)
Eastern Mediterranean	324 394 (6%)	-14%	9 147 412 (6%)	6 461 (7%)	1%	183 431 (6%)
Africa	42 090 (1%)	-15%	3 316 851 (2%)	1 000 (1%)	-13%	82 870 (3%)
Western Pacific	132 543 (2%)	1%	2 470 005 (2%)	1 266 (1%)	-3%	37 488 (1%)
Global	5 705 981 (100%)	0%	151 812 556 (100%)	93 523 (100%)	6%	3 186 817 (100%)

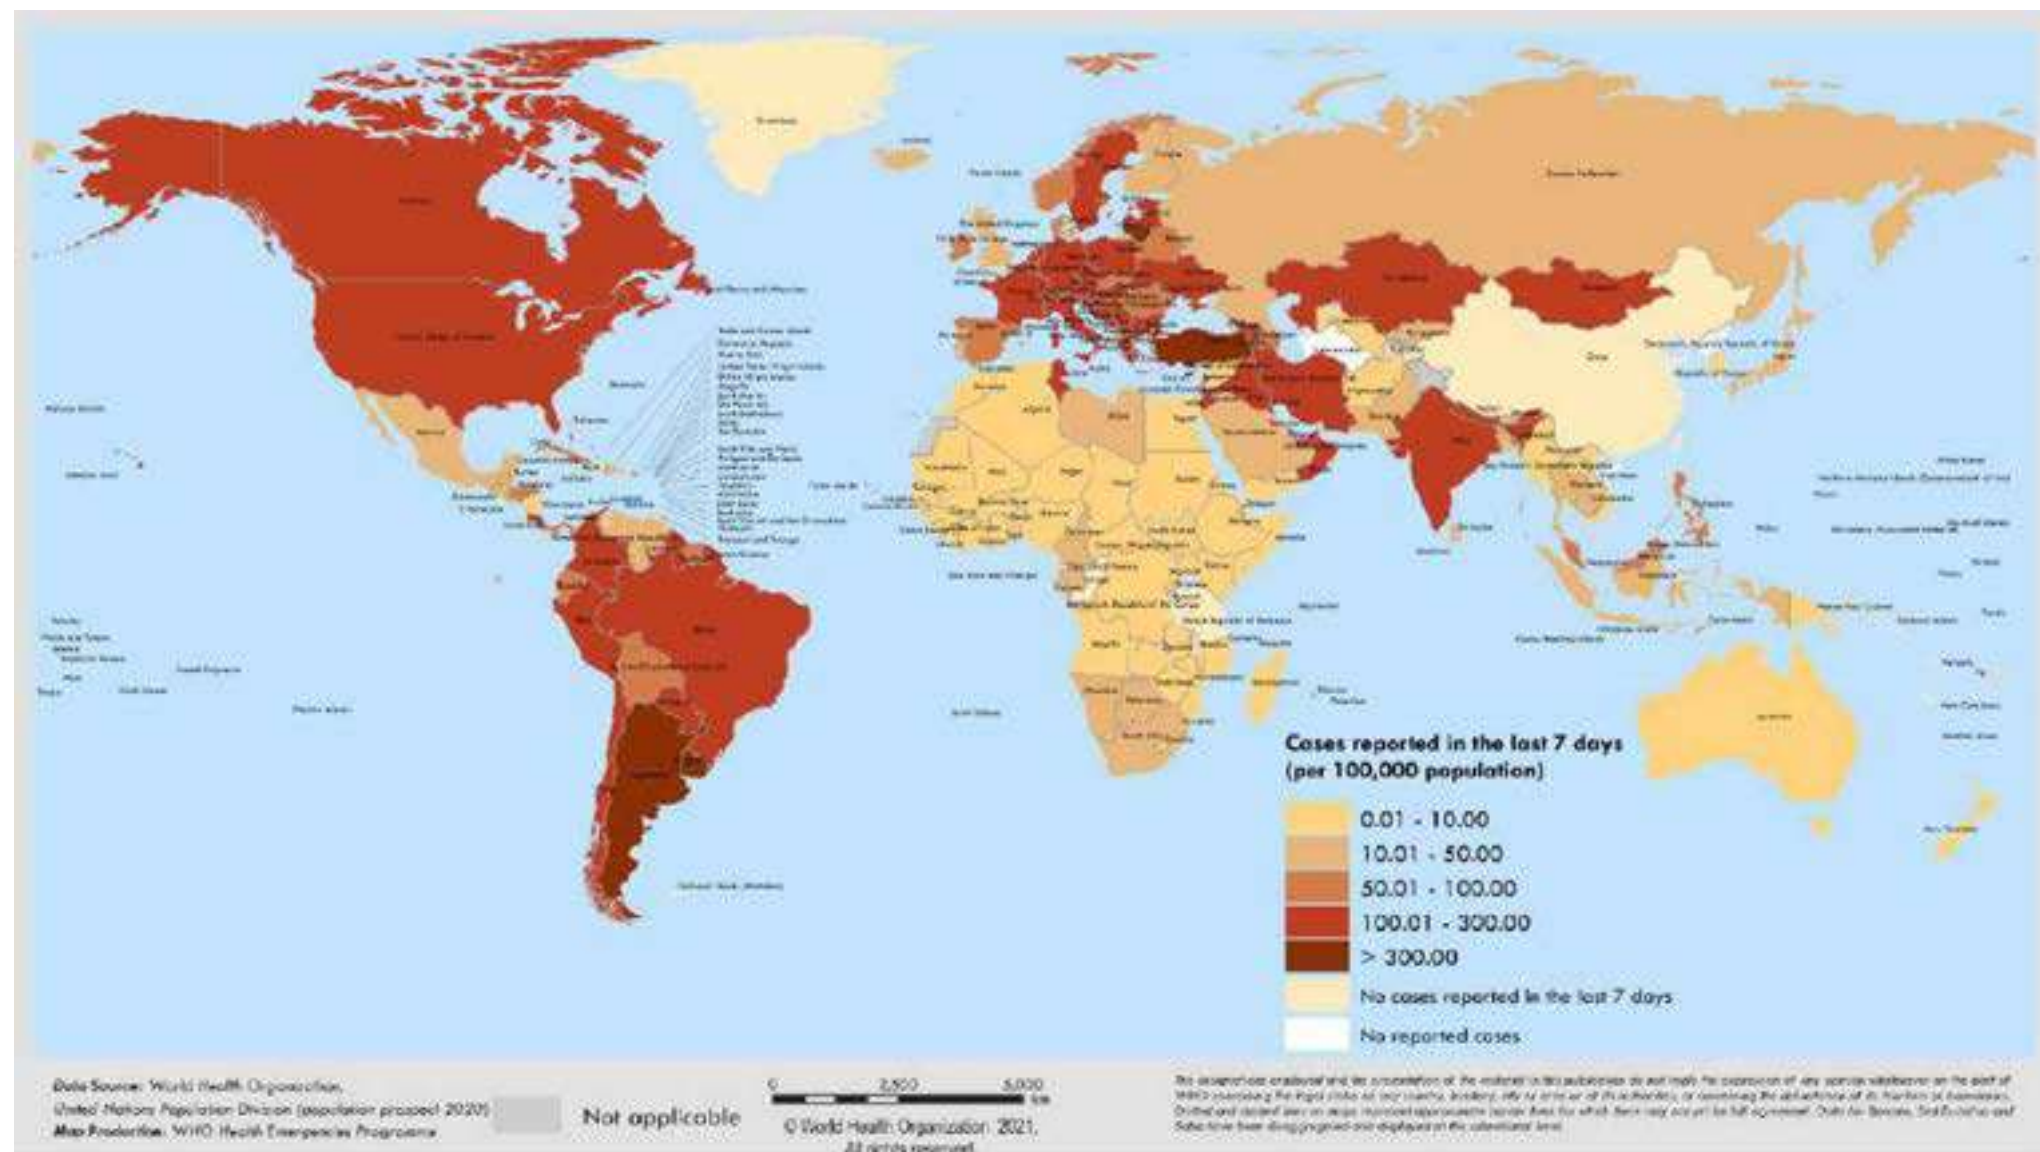

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior

**See Annex: Data, table and figure notes

Special Focus: World Hand Hygiene Day, 5 May 2021

For many infectious pathogens, including SARS-CoV-2, good hand hygiene practices are tremendously important for reducing the risk of transmission, as part of a wider package of public health and infection prevention and control (IPC) measures. Launched in 2009 and celebrated annually on 5 May, [World Hand Hygiene Day](#) (WHHD) aims to promote visibility and sustainability of hand hygiene in healthcare, and to bring people together in support of hand hygiene improvement around the world. This year, in the [Year of Health and Care Workers](#), WHHD 2021 focuses on achieving effective hand hygiene action at the point of care and redouble our efforts to ensure that hand hygiene is a priority for action.

Health workers, patients and families, infection prevention and control practitioners, health facility managers, policy-makers, vaccinators and the general public all have an important role to play and are [encouraged to practice good hand hygiene](#), because:

- Appropriate hand hygiene reduces the risk of infection from many pathogens, including SARS-CoV-2, both in the general population¹ and among health workers.²
- Appropriate hand hygiene prevents up to 50% of avoidable infections acquired during health care delivery.³
- Investing in hand hygiene yields huge returns – hand hygiene policies can generate economic savings averaging 16 times the cost of their implementation.⁴
- Effective hand hygiene reduces mortality and disabilities due to health care-associated infections.⁴

Effective hand hygiene can be achieved by using the [WHO hand hygiene multimodal improvement strategy](#), which has proved to be highly impactful, leading to a significant improvement in key hand hygiene indicators, a reduction in health care-associated infections and antimicrobial resistance, and substantially helping to stop outbreaks.⁵

Despite overwhelming evidence showing the impact of good hand hygiene practices, many gaps still exist that show inadequate infrastructure and supplies leading to gaps in hand washing behaviour, in particular in health care. For example:

- Globally, 1 in 4 health care facilities do not have access to basic water services.⁶
- 1 in 3 facilities lack hand hygiene resources at the point of care,⁶ and in low-income countries only 17% of facilities have continuous availability of alcohol-based hand rub supplies, compared to 75% in high-income countries.⁷
- Compliance with hand hygiene best practices is only around 9% during care of critically ill patients in low-income countries, while levels of hand hygiene compliance for high-income countries rarely exceed 70%.^{8,9}

Through the global [Hand Hygiene for All initiative](#), WHO and UNICEF call upon policy and decision makers to invest in hand hygiene improvement as a whole-of-society effort, and show tangible action to strengthen the enabling environment and ensure vital hand hygiene products and WASH services are readily accessible, across the health system, and for everyone in their community.

WHO provides guidance on the [resources considerations](#) needed for making such an investment across the health system and WHHD 2021 represents a critical time for everyone to show commitment to hand hygiene improvement.

For more information, see WHHD [key facts and figures](#), and [how to get involved](#) in the campaign.

Seconds save lives – Clean your hands!

Special Focus: WHO partnership with SeroTracker — synthesizing “real-time” seroprevalence data to support global pandemic response

As of 2 May 2021, there have been over 151 million confirmed COVID-19 cases reported to WHO worldwide; however, this does not fully represent the true extent of infection with the SARS-CoV-2 virus. This is because current surveillance strategies and testing capacities often do not typically include infected individuals who were asymptomatic, often miss mildly symptomatic cases, those who do not have access to testing. Studies measuring seroprevalence are crucial tools for pandemic surveillance and to provide data to inform public health interventions. These studies are designed to measure antibodies against SARS-CoV-2 in a population at a point in time. They provide a more robust estimate of the true extent of the pandemic, population susceptibility to infection (antibody-mediated immunity), and provide data to estimate other critical parameters (e.g. infection fatality ratios) – all of which are key metrics that inform public health decision-making at local, national and international levels.

To date, more than 950 serosurveys have reported results either through pre-prints or peer-reviewed publications. Most available studies have been conducted in high-income countries and many have not used standardized methods, including the use of standardized protocols or used well-performing antibody tests, making it challenging to compare findings between countries, regions and over time. The [WHO is supporting countries through the Unity Studies](#) initiative, which provides technical, operational and financial support for countries around the world, particularly low- and middle-income countries (LMICs), to build research capacity and conduct serosurveys following a standardized protocols and well-performing, easy to use antibody tests protocols, including a [population-based, age-stratified seroepidemiological investigation protocol](#) and studies of health care workers.

To support the reporting of available seroprevalence studies, WHO has partnered with SeroTracker – a knowledge hub that tracks, displays, maps and synthesizes SARS-CoV-2 seroprevalence and serosurveillance efforts worldwide.^{1–3} Through its partnership with SeroTracker, WHO aims to create the world’s largest repository of seroprevalence data, including results from countries performing one or more of the Unity Studies with other SARS-CoV-2 serosurveys. These efforts will help to map COVID-19 infections globally.

Data and information from available SARS-CoV-2 seroprevalence studies will be visualized on the [SeroTracker digital dashboard and data platform](#), which will include a webpage dedicated to display research aligned with WHO Unity Studies. The platform will allow users to filter results based on study date, WHO Region, participant demographics; visualize results through maps and graphics; and access study publications.

The WHO-SeroTracker database will additionally be used to regularly synthesize SARS-CoV-2 serosurvey findings to inform public health strategies. Synthesizing findings, through comprehensive meta-analyses across countries and regions, is crucial to understand the global extent of SARS-CoV-2 infection, to better inform decision making, and to identify gaps in knowledge.

Special Focus: Update on SARS-CoV-2 variants

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they result in changes in public health and social measures (PHSM) implementation by national health authorities. Systems have been established to detect “signals” of potential variants of concern (VOCs) or variants of interest (VOIs) and assess these based on the risk posed to global public health (see also [working definitions](#)). National authorities may choose to designate other variants of local interest/concern. Detailed information on currently circulating VOCs and VOIs is available in previously published editions of the [Weekly Epidemiological Update](#). Here we provide a brief update on the geographical distribution of the three VOCs as of 4 May 2021, as well as an update on detected VOIs (Table 2).

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs and VOIs has continued to increase. Since our last update on 27 April, VOC 202012/01 has been detected in three additional countries, variant 501Y.V2 in ten additional countries, and variant P.1 has been reported in three additional countries. As of 4 May, a total 142 countries have reported VOC 202012/01 (Figure 3), 97 countries variant 501Y.V2 (Figure 4), and 56 countries variant P.1 (Figure 5) – see also Annex 2. The information presented here should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and prioritization of samples for sequencing between countries.

Table 2: SARS-CoV-2 variants of concern (VOC) and variants of interest (VOI), as of 4 May 2021*

	Nextstrain clade	Pango lineage	GISAID clade	Alternate name	First detected in	Earliest samples	Characteristic spike mutations

Figure 5. Countries, territories and areas reporting SARS-CoV-2 variant P.1, as of 4 May 2021

WHO recommendations

Virus evolution is expected and the more SARS-CoV-2 circulates, the more opportunities it has to mutate. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of PHSM and infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

WHO regional overviews

African Region

The African Region reported over 42 000 new cases and 1000 new deaths, a 15% and a 13% decrease respectively compared to the previous week. Overall, cases and deaths trended downward since peaking in mid-January 2021; however, countries throughout the Region continue to report sustained transmission and increases in some areas. The highest numbers of new cases were reported from South Africa (8472 new cases; 14.3 new cases per 100 000 population; a 3% decrease), Ethiopia (7107 new cases; 6.2 new cases per 100 000; a 34% decrease), and Cameroon (4609 new cases; 17.4 new cases per 100 000; an 8% increase).

The highest numbers of new deaths were reported from South Africa (281 new deaths; 0.5 new deaths per 100 000 population; a 32% decrease), Ethiopia (178 new deaths; 0.2 new deaths per 100 000; a 12% decrease), and Kenya (141 new deaths; 0.3 new deaths per 100 000; a 1% increase).

Region of the Americas

The Region of the Americas reported over 1.3 million new cases and over 36 000 new deaths, a 5% decrease and a 1% increase respectively compared to the previous week. Case incidence has decreased for a second consecutive week. The highest numbers of new cases were reported from Brazil (421 933 new cases; 198.5 new cases per 100 000; a 4% increase), the United States of America (345 692 new cases; 104.4 new cases per 100 000; a 15% decrease), and Argentina (152 711 new cases; 337.9 new cases per 100 000; an 8% decrease). These three countries account for 69% of cases reported in the region this week.

The highest numbers of new deaths were reported from Brazil (17 365 new deaths; 8.2 new deaths per 100 000; a 2% decrease), the United States of America (4728 new deaths; 1.4 new deaths per 100 000; a 5% decrease), and Colombia (3274 new deaths; 6.4 new deaths per 100 000; a 14% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 324 000 new cases and over 6400 new deaths, a 14% decrease and a 1% increase respectively compared to the previous week. The number of cases has decreased for a second consecutive week, while deaths continue to increase for a tenth consecutive week. The highest numbers of new cases were reported from the Islamic Republic of Iran (139 118 new cases; 165.6 new cases per 100 000; a 14% decrease), Iraq (45 078 new cases; 112.1 new cases per 100 000; a 17% decrease), and Pakistan (35 503 new cases; 16.1 new cases per 100 000; an 11% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (2970 new deaths; 3.5 new deaths per 100 000; a 6% increase), Pakistan (958 new deaths; 0.4 new deaths per 100 000; a 6% increase), and Tunisia (577 new deaths; 4.9 new deaths per 100 000; a 12% increase).

European Region

The European Region reported over 1.1 million new cases and over 22 000 new deaths, a marked 22% and a 12% decrease respectively compared to the previous week. Cases have decreased for a fourth consecutive week, and deaths have also decreased for a third consecutive week. The highest numbers of new cases were reported from Turkey (257 992 new cases; 305.9 new cases per 100 000; a 32% decrease), France (163 666 new cases; 251.6 new cases per 100 000; a 23% decrease), and Germany (129 404 new cases; 155.6 new cases per 100 000; an 11% decrease).

The highest numbers of new deaths were reported from Poland (2653 new deaths; 7.0 new deaths per 100 000; a 22% decrease), the Russian Federation (2630 new deaths; 1.8 new deaths per 100 000; a 1% decrease), and Turkey (2493 new deaths; 3.0 new deaths per 100 000; a 4% increase).

South-East Asia Region

The South-East Asia Region reported over 2.7 million new cases and over 25 000 new deaths, a 19% and a 48% increase respectively compared to the previous week. India is currently driving the vast majority of this upward trend; however, notable increases have also been observed elsewhere in the region, for example in Nepal and Sri Lanka. Among ten countries which have reported cases in this region, eight countries reported an increase in case incidence this week. The highest numbers of new cases were reported from India (2 597 285 new cases; 188.2 new cases per 100 000; a 20% increase), Indonesia (36 088 new cases; 13.2 new cases per 100 000; a 3% decrease), and Nepal (31 806 new cases; 109.2 new cases per 100 000; a 137% increase).

The highest numbers of new deaths were reported from India (23 231 new deaths; 1.7 new deaths per 100 000; a 53% increase), Indonesia (1152 new deaths; 0.4 new deaths per 100 000; a 2% decrease), and Bangladesh (558 new deaths; 0.3 new deaths per 100 000; a 17% decrease).

Western Pacific Region

The Western Pacific Region reported over 132 000 new cases and over 1200 new deaths, a 1% increase and a 3% decrease respectively compared to the previous week. Case incidence continued an upward trend which has been reported for the past eight weeks, while deaths decreased for a third consecutive week. The highest numbers of new cases were reported from the Philippines (57 238 new cases; 52.2 new cases per 100 000; a 10% decrease), Japan (35 084 new cases; 27.7 new cases per 100 000; a 9% increase), and Malaysia (21 342 new cases; 65.9 new cases per 100 000; a 23% increase).

The highest numbers of new deaths were reported from the Philippines (680 new deaths; 0.6 new deaths per 100 000; a 21% decrease), Japan (383 new deaths; 0.3 new deaths per 100 000; a 32% increase), and Malaysia (95 new deaths; 0.3 new deaths per 100 000; a 70% increase).

Key weekly updates

WHO Director-General's key message

[Opening remarks at the media briefing on COVID-19](#) – 3 May 2021:

- More cases of COVID-19 have been reported globally in the past two weeks than during the first six months of the pandemic.
- Sweden will donate 1 million doses of AstraZeneca - Vaxzevria vaccines to COVAX, which follows similar donations by France, New Zealand and Norway, with positive signs from some other countries.
- The Access to COVID-19 Tools Accelerator currently faces a funding gap of 19 billion US dollars, and we estimate that we will need a further 35 to 45 billion dollars next year to vaccinate most adults around the world. The G7 countries could mobilize a substantial portion of these funds themselves and lead a global effort to accelerate vaccination around the world.

*Newly reported in this update.

"Verified" indicates that information for this variant was received by WHO from official sources.

"Under verification" indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

Variant P.1 for Saint Martin was excluded this week based on further information received.

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 746 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.

- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 25 April 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: SARS-CoV-2 variants](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Globally, new COVID-19 cases increased for the ninth consecutive week, with nearly 5.7 million new cases reported in the last week – surpassing previous peaks (Figure 1). The number of new deaths increased for the sixth consecutive week, with over 87 000 new deaths reported. This week, all regions are reporting decreases in case incidence apart from the South-East Asia and Western Pacific regions. For the third consecutive week, the South-East Asia region reported the highest relative increases in both case and death incidences (Table 1). While a number of countries in the region are reporting upward trends, India accounts for the vast majority of cases from this regional trend and 38% of global cases reported in the past week. Similarly, all but two regions, South-East Asia and Eastern Mediterranean, reported declines in new deaths this week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 25 April 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from India (2 172 063 new cases; 52% increase), the United States of America (406 001 new cases; 15% decrease), Brazil (404 623 new cases; 12% decrease), Turkey (378 771 new cases; 9% decrease), and France (211 674 new cases; 9% decrease).

Special Focus: Update on SARS-CoV-2 variants

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor SARS-CoV-2 variants of interest (VOIs) and variants of concern (VOCs), and assess these and other emerging variants based on the risk posed to global public health, including impacts on epidemiology and public health and social measures (PHSM). Here we provide an update on the geographical distribution, and emerging evidence surrounding phenotypic characteristics of designated VOIs and VOCs (Tables 2).

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing and sharing full genome sequences with publicly available platforms such as GISAID, the number of countries/areas/territories (hereafter countries) reporting VOCs continues to increase. Since our last update on 20 April, VOC 202012/01 has been detected in three additional countries, variant 501Y.V2 in three additional countries, and variant P.1 in two additional countries. As of 27 April, a total 139 countries have reported VOC 202012/01 (Figure 3), 87 countries VOC 501Y.V2 (Figure 4), and 54 countries VOC P.1 (Figure 5) – see also Annex 2. These distributions should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and prioritization of samples for sequencing between countries.

Table 2: SARS-CoV-2 variants of interest (VOI) and variants of concern (VOC), as of 27 April 2021

	Nextstrain clade	Pango lineage	GISAID clade	Alternate name	First detected in	Earliest samples	Characteristic spike mutations

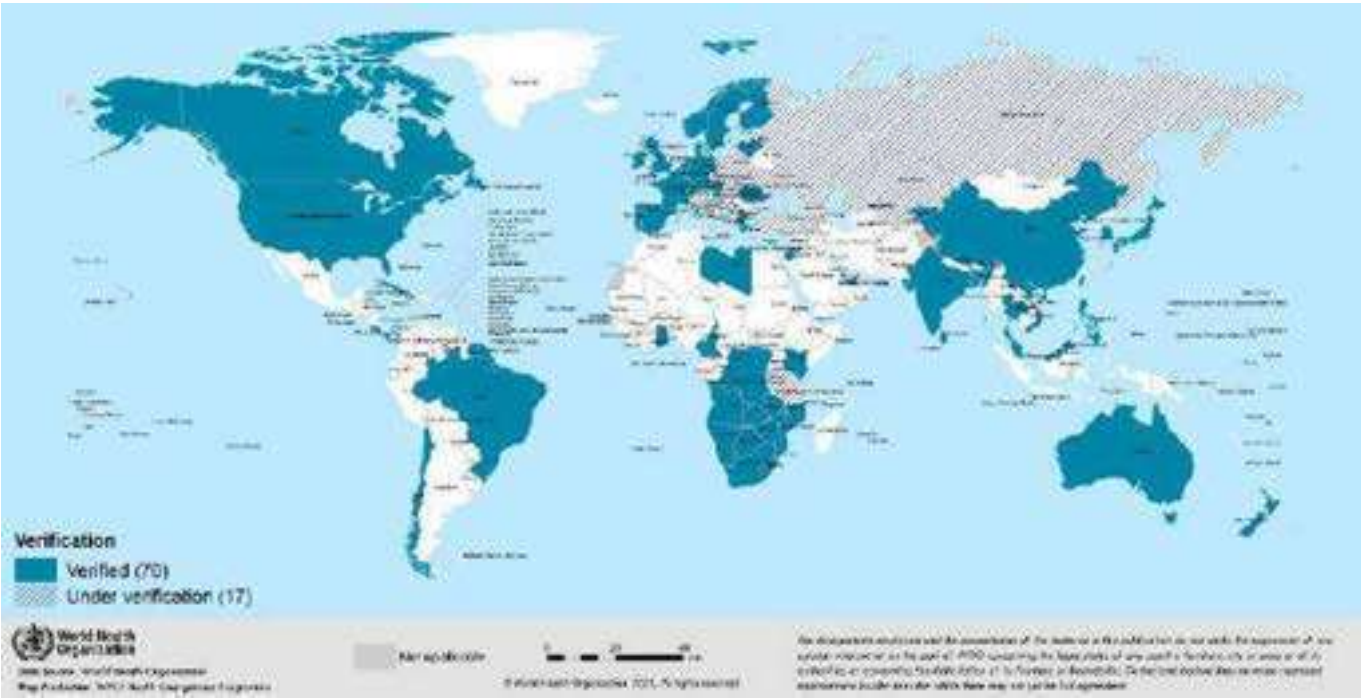

Figure 5. Countries, territories and areas reporting SARS-CoV-2 variant P.1, as of 27 April 2021

Vaccine performance against VOCs

Available evidence on vaccine performance against VOCs have been highlighted in previous editions of the Weekly Epidemiological Update, most recently [13 April](#), and are summarised in Table 3.

Table 3: Summary of vaccine performance against variants of concern (VOC) relative to ancestral stains

VOC 202012/01 (B.1.1.7)	501Y.V2 (B.1.351)	P.1 (B.1.1.28.1)
Efficacy/effectiveness against disease or infection		
<p>Protection retained against disease:</p> <ul style="list-style-type: none"> No/minimal loss: AstraZeneca-Vaxzevria, Novavax-Covavax, Pfizer BioNTech-Comirnaty¹⁻¹⁰ <p>Asymptomatic infection:</p> <ul style="list-style-type: none"> No/minimal loss: Pfizer BioNTech-Comirnaty^{11,12} Moderate/substantial loss (inconclusive, limited sample size): AstraZeneca-Vaxzevria² 	<p>Reduced protection against disease, limited evidence</p> <p>Severe disease:</p> <ul style="list-style-type: none"> No/minimal loss: Janssen Ad26.COV 2.5³³ <p>Mild-moderate disease:</p> <ul style="list-style-type: none"> Moderate loss: Janssen-Ad26.COV 2.5, Novavax-Covavax^{33,34} Substantial loss (Inconclusive, limited sample size): AstraZeneca-Vaxzevria³⁵ <p>Asymptomatic infection:</p> <ul style="list-style-type: none"> No evidence 	<p>Limited evidence</p> <ul style="list-style-type: none"> No/minimal loss: Sinovac-CoronaVac⁴²
Neutralization		
<ul style="list-style-type: none"> No/minimal loss: Bharat-Covaxin, Gamaleya-Sputnik V, Moderna-mRNA-1273, Novavax-Covavax, Pfizer BioNTech-Comirnaty, Beijing CNBG-BBIBP-CorV, Sinovac-CoronaVac¹³⁻³² Minimal/moderate loss: AstraZeneca-Vaxzevria^{2,28} 	<ul style="list-style-type: none"> Minimal/modest loss: Beijing CNBG-BBIBP-CorV, Sinovac-CoronaVac^{36,37} Minimal to large loss: Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty^{13,14,18-20,22-25,27-30,36,38-41} Moderate to substantial loss: AstraZeneca-Vaxzevria, Gamaleya-Sputnik V, Novavax-Covavax^{20,28,31,40} 	<ul style="list-style-type: none"> No/Minimal reduction: AstraZeneca-Vaxzevria, Sinovac-CoronaVac^{28,43} Minimal/moderate reduction: Moderna-mRNA-1273, Pfizer BioNTech-Comirnaty^{14,15,22,25,27,28,39,41,43,44}

Further to this, there is growing real-world evidence of the effectiveness of Pfizer BioNTech-Comirnaty vaccine against symptomatic disease as well as severe disease in health workers and adults in the United Kingdom and Israel during times when VOC 202012/01 was circulating or dominant, providing support for neutralization and vaccine efficacy (VE) results. Real-world evidence also points to high effectiveness against asymptomatic infection.³⁻¹¹ Analysis of nationwide surveillance data in Israel reported a VE of 94.1% (93.5-94.6) against asymptomatic infection ≥ 14 days post second dose among a large cohort of adults 16 years and older.¹¹ A second study reported a four-fold decrease in the risk of asymptomatic infection ≥ 12 days post dose one among health workers in the United Kingdom.¹²

Two effectiveness studies conducted in the United Kingdom have reported VOC 202012/01-specific VE estimates for two doses of Pfizer BioNTech-Comirnaty, and found no difference in effectiveness of the vaccine against disease caused by VOC 202012/01 as compared to other variants.^{3,9}

There is also growing real-world evidence showing a single dose of AstraZeneca-Vaxzevria is effective against symptomatic disease and infection in VOC 202012/01 settings.^{3,6-8} Data is currently lacking on the effectiveness of two doses of AstraZeneca. Although moderate to substantial loss was observed with the AstraZeneca-Vaxzevria vaccine, the confidence intervals are broad and caution should be taken interpreting the results, given the limited sample size.²

Phase III clinical trial results from South Africa show vaccine efficacy of Janssen-Ad26.COV 2.5 vaccine to be 52% (95% CI: 30.3-67.4) against moderate to severe/critical disease when variant 501Y.V2 made up 95% of sequenced virus. Efficacy against severe critical disease was 73.1% (40.0-89.4), comparable to that found in the USA.³³ Although moderate to substantial loss was observed with the AstraZeneca-Vaxzevria vaccine, the confidence intervals are broad and caution should be taken interpreting the results, given the limited sample size.³⁵

Variants of interest B.1.617

Emerging SARS-CoV-2 variants within Pango lineage B.1.617 were recently reported as a VOI from India and has recently been designated as VOIs by WHO. As of 27 April, over 1200 sequences have been uploaded to GISAID and assigned to lineage B.1.617 (collectively) from at least 17 countries; most sequences were uploaded from India, the United Kingdom, USA and Singapore.⁴⁵ However, this lineage comprises several sub-lineages, including B.1.617.1, B.1.617.2 and B.1.617.3, which slightly differ by their characteristic mutations. Both B.1.617.1 and B.1.617.2 were first identified in India in December 2020, and have been detected at increasing prevalence concurrent to the major upsurge observed in the country. B.1.617.3 was first detected in India in October 2020, but relatively fewer viruses matching this sub-lineage have been reported to date.

B.1.617 includes several mutations present in other VOIs / VOCs that have been associated with phenotypic impacts. Three characteristic mutations of this variant include L452R, P681R, and E484Q (the latter observed in sub-lineages B.1.617.1 and B.1.617.3). L452R has been identified in another VOI, B.1.427/ B.1.429, which has been associated with increased transmissibility, a reduction in neutralization by some (but not all) monoclonal antibody treatments, and a moderate reduction in neutralization in post-vaccination sera in the USA.⁴⁶ P681R is adjacent to the furin cleavage site, and (together with other mutations) may enhance binding and subsequent cleavage of the spike protein and enhances systemic infection and membrane fusion; potentially resulting in enhanced transmission.⁴⁷ Laboratory studies suggest that convalescent samples from individuals who had natural infection may have reduced neutralization against variants with an E484Q mutation.⁴⁸ Preliminary laboratory studies of a small number of convalescent sera samples of COVID-19 cases (n=17) and recipients of Novavax-Covaxin (n=28) were able to neutralize B.1.617.⁴⁹

In India, heterogeneity in B.1.617 geographic distribution is observed across regions, with co-circulation of other VOCs (including VOC 202012/01 and 501Y.V2) and other variants (e.g., B.1.618), which collectively may be playing a role in the current resurgence in this country. Indeed, studies have highlighted that the spread of

the second wave has been much faster than the first.⁵⁰ Preliminary modelling by WHO based on sequences submitted to GISAID suggest that B.1.617 has a higher growth rate than other circulating variants in India, suggesting potential increased transmissibility, with other co-circulating variants also demonstrating increased transmissibility. Other drivers may include challenges around the implementation and adherence to public health and social measures (PHSM), and social gatherings (including mass gatherings during cultural and religious celebrations, and elections). Further investigation is needed to understand the relative contribution of these factors.

It remains unclear how generalizable laboratory-based studies of limited sample sizes, as well as studies of other variants with similar key mutations, are to the wider circulating B.1.617 variants. Further robust studies into the phenotypic impacts of these variants, including impacts on epidemiological characteristics (transmissibility, severity, reinfection risk, etc.) and impact on countermeasures, are urgently needed.

WHO recommendations

Virus evolution is expected and the more SARS-CoV-2 circulates, the more opportunities it has to mutate. Reducing transmission through established and proven disease control methods such as those outlined in the [COVID-19 Strategic Preparedness and Response Plan](#), as well as avoiding introductions into animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of PHSM and infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and to detect unusual events.

WHO regional overviews

African Region

The African Region reported over 49 000 new cases and over 1100 new deaths, a 9% and a 1% decrease respectively compared to the previous week. The number of weekly cases continues to oscillate over the last nine weeks, with an overall decreasing trend in deaths observed since the peak in mid-January. The highest numbers of new cases were reported from Ethiopia (10 719 new cases; 9.3 new cases per 100 000 population; a 17% decrease), South Africa (8690 new cases; 14.7 new cases per 100 000; a 7% increase), and Kenya (5031 new cases; 9.4 new cases per 100 000; an 18% decrease).

The highest numbers of new deaths were reported from South Africa (414 new deaths; 0.7 new deaths per 100 000 population; a 9% decrease), Ethiopia (203 new deaths; 0.2 new deaths per 100 000; a 12% increase), and Kenya (140 new deaths; 0.3 new deaths per 100 000; a 5% increase).

Region of the Americas

The Region of the Americas reported over 1.4 million new cases and over 36 000 new deaths, an 8% and a 7% decrease respectively compared to the previous week. The region has reported a decreasing trend in new cases in the last week after eight weeks of a gradual increase, the trend in new deaths also decreased in the last week. The highest numbers of new cases were reported from the United States of America (406 001 new cases; 122.7 new cases per 100 000; a 15% decrease), Brazil (404 623 new cases; 190.4 new cases per 100 000; a 12% decrease), and Argentina (166 024 new cases; 367.3 new cases per 100 000; a 3% increase).

The highest numbers of new deaths were reported from Brazil (17 667 new deaths; 8.3 new deaths per 100 000; a 12% decrease), the United States of America (4951 new deaths; 1.5 new deaths per 100 000; a 4% decrease), and Colombia (2882 new deaths; 5.7 new deaths per 100 000; a 26% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 378 000 new cases and over 6300 new deaths, a 2% decrease and a 17% increase respectively compared to the previous week. The trend in new cases has plateaued after ten weeks of an increase, whereas the trend in new deaths continues to increase sharply for the ninth consecutive week. The highest numbers of new cases were reported from the Islamic Republic of Iran (161 594 new cases; 192.4 new cases per 100 000; a 3% decrease), Iraq (54 301 new cases; 135.0 new cases per 100 000; a 3% increase), and Pakistan (39 858 new cases; 18.0 new cases per 100 000; a 17% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (2793 new deaths; 3.3 new deaths per 100 000; a 33% increase), Pakistan (905 new deaths; 0.4 new deaths per 100 000; an 18% increase), and Tunisia (514 new deaths; 4.3 new deaths per 100 000; a 7% increase).

European Region

The European Region reported over 1.4 million new cases and over 25 000 new deaths, a 12% and a 5% decrease respectively compared to the previous week. The trend in both new cases and deaths is decreasing in the last two weeks. The highest numbers of new cases were reported from Turkey (378 771 new cases; 449.1 new cases per 100 000; a 9% decrease), France (211 674 new cases; 325.5 new cases per 100 000; a 9% decrease), and Germany (145 156 new cases; 174.5 new cases per 100 000; a 1% increase).

The highest numbers of new deaths were reported from Poland (3383 new deaths; 8.9 new deaths per 100 000; a 6% decrease), the Russian Federation (2650 new deaths; 1.8 new deaths per 100 000; a 2% increase), and Ukraine (2537 new deaths; 5.8 new deaths per 100 000; an 8% decrease).

South-East Asia Region

The South-East Asia Region reported over 2.2 million new cases and over 17 000 new deaths, a 49% and an 81% increase respectively compared to the previous week. A very sharp rise in new cases and new deaths reported since early in March continues. The main driver of this increase in the region is the high numbers of new cases reported from India (2 172 063 new cases; 157.4 new cases per 100 000; a 52% increase). Additionally, high numbers of new cases were reported from Indonesia (37 029 new cases; 13.5 new cases per 100 000; similar to previous week), and Bangladesh (27 148 new cases; 16.5 new cases per 100 000; a 25% decrease).

The highest numbers of new deaths were reported from India (15 161 new deaths; 1.1 new deaths per 100 000; a 93% increase), Indonesia (1172 new deaths; 0.4 new deaths per 100 000; a 32% increase), and Bangladesh (669 new deaths; 0.4 new deaths per 100 000; an 8% increase).

Western Pacific Region

The Western Pacific Region reported nearly 132 000 new cases and over 1300 new deaths, a 3% increase and a 10% decrease respectively compared to the previous week. New weekly cases continue to increase for the seventh consecutive week while new deaths have decreased in the last two weeks following a peak in early April. The highest numbers of new cases were reported from the Philippines (63 364 new cases; 57.8 new cases per 100 000; a 13% decrease), Japan (32 312 new cases; 25.5 new cases per 100 000; a 22% increase), and Malaysia (17 393 new cases; 53.7 new cases per 100 000; a 27% increase).

The highest numbers of new deaths were reported from the Philippines (864 new deaths; 0.8 new deaths per 100 000; a 19% decrease), Japan (291 new deaths; 0.2 new deaths per 100 000; a 21% increase), and Malaysia (56 new deaths; 0.2 new deaths per 100 000; a 14% increase).

Key weekly updates

WHO Director-General's key message

[Opening remarks at the media briefing on COVID-19](#) – 23 April 2021:

- One year ago, WHO and many partners came together to launch the Access to COVID-19 Tools (ACT) Accelerator. The ACT Accelerator was conceived to rapidly develop vaccines, diagnostics and therapeutics; and to provide equitable access to those tools. The first objective has been achieved, though we have a long way to go on the second objective.
- We need countries and companies to:
 - share financial resources, to fully fund the ACT Accelerator;
 - share vaccine doses to protect the most at-risk, not just the most-rich;
 - share technology, know-how and intellectual property to scale up production; and
 - be transparent about their bilateral dose donations, so we know who has what.
- The ACT Accelerator needs 19 billion US dollars this year.

*Newly reported in this update.

"Verified" indicates that information for this variant was received by WHO from official sources.

"Under verification" indicates that information for this variant was received by WHO from unofficial sources and will be reviewed as more information become available.

Variants VOC 202012/01 for Syrian Arab Republic, and 501Y.V2 for Uganda, were excluded this week based on further information received.

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 746 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.

- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 18 April 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: Update on WHO COVID-19 global rapid risk assessment](#)
- [Special focus: Pandemic influenza surveillance – drawing a parallel with the COVID-19 pandemic](#)
- [Special focus: SARS-CoV-2 variants](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Globally, new COVID-19 cases increased for the eighth consecutive week, with more than 5.2 million new cases reported in the last week – surpassing the previous peak in early January 2021 (Figure 1). The number of new deaths increased for the fifth consecutive week, an 8% increase as compared to the previous with over 83 000 new deaths reported. Last week the reported cumulative COVID-19 death toll surpassed 3 million lives; the pace of deaths is accelerating, it took nine months to reach 1 million deaths, another four to surpass 2 million, and just three to reach 3 million deaths.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 18 April 2021**

**See [Annex: Data, table and figure notes](#)

While all regions except the European Region reported an increase in incident cases in the last week, the largest increase continues to be reported by the South-East Asia Region, largely driven by India, followed by the Western Pacific Region (Table 1). All regions except the European and Western Pacific regions reported an increase in the number of weekly deaths, with the largest increase in the South-East Asia Region due to an

increase in deaths in India, followed by the Eastern Mediterranean Region, largely due to an increase in new deaths in the Islamic Republic of Iran.

The countries reporting the highest number of new cases represent three of the six WHO regions: India (1 429 304 new cases; 64% increase), the United States of America (477 778 new cases; 2% increase), Brazil (459 281 new cases; 1% decrease), Turkey (414 312 new cases; 17% increase), and France (233 275 new cases; 12% decrease).

Table 1. Newly reported and cumulative COVID-19 cases and deaths, by WHO Region, as of 18 April 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 525 505 (29%)	7%	59 551 000 (42%)	39 482 (47%)	8%	1 444 736 (48%)
Europe	1 624 060 (31%)	-3%	49 208 464 (35%)	26 302 (32%)	-3%	1 035 294 (34%)
South-East Asia	1 518 708 (29%)	57%	17 696 534 (13%)	9 447 (11%)	49%	237 832 (8%)
Eastern Mediterranean	386 176 (7%)	6%	8 444 694 (6%)	5 460 (7%)	23%	170 580 (6%)
Africa	54 297 (1%)	7%	3 225 261 (2%)	1 170 (1%)	14%	80 715 (3%)

Special Focus: Update on WHO COVID-19 global rapid risk assessment, 13 April 2021

As the COVID-19 pandemic, response and our understanding of the SARS-CoV-2 virus continue to evolve, WHO's most recent assessment is that the global public health risk remains very high. Under the Emergency Response Framework, WHO undertakes risk assessments and situation analyses on a regular basis to inform our response to emerging issues. In addition, WHO periodically formally reviews the current risk status of risks through an in-depth hazard, exposure and context assessment; as well as a review of the vulnerabilities and capacities to respond and to investigate the current risk to human health, risks of ongoing spread globally, and risk of insufficient control capacities. Such assessments are used as an internal-WHO decision-making tool, but they also additionally to support independent deliberations, including (but not limited to) meetings of the IHR Emergency Committee. Ten COVID-19 rapid risk assessments have been undertaken to date, and additional assessments have been completed for specific events surrounding the emergence of SARS-CoV-2 variants of concern (VOCs). Here, we provide a synopsis of the most recent in-depth global rapid risk assessment.

The COVID-19 pandemic shows no signs of easing, with global case and death incidence increasing at a concerning rate since mid-February 2021; a third of the global cumulative COVID-19 cases and deaths has been reported in the last three months alone, with weekly cases reaching similar levels as the previous peak in January 2021. Marked geographical variation in the pandemic trajectory continues to be observed at regional and country levels, with sharp rises observed in the South-East Asia, Eastern Mediterranean and Western Pacific regions in recent weeks. The global infection fatality ratio (IFR) was estimated between 0.1% to 1.0%, an increase from January largely driven by an increase in the Region of the Americas. Globally mortality rates continue to be higher for those over 40 years as well as for males as compared to females.

The resurgences in the last four months have likely been driven in part by both the emergence of SARS-CoV-2 VOCs and inconsistent use/early easing of public health and social measures (PHSM). As surveillance and sequencing activities to detect SARS-CoV-2 variant cases are strengthened, the number of countries reporting the three variants designated as global VOCs has increased. All three VOCs are associated with increased transmission. Additionally, some have been associated with increased disease severity (VOC 202012/01 and 501Y.V2), increased risk of immune escape (501Y.V2 and P.1), and/or significant reductions in neutralization (501Y.V2 and P.1) by convalescent or post-vaccine sera compared to wild-type/non-VOC variants, suggesting increased risk of vaccine failure or reinfection. In addition to the VOCs, six variants have thus far been designated as SARS-CoV-2 variants of interest (VOIs), and a further 19 variants are currently under investigation, highlighting that especially as global incidence remains high, there is continued risk of emergence of more variants with phenotypic implications and global importance in the coming months.

The high burden of COVID-19 globally has continued to challenge surveillance systems, leading to a large gap in the completeness of demographic information shared for reported cases. In line with the WHO surveillance guidelines, efforts are being made to strengthen surveillance and reporting, however, many challenges persist especially for low-income countries. The ongoing pandemic also continues to challenge public health and healthcare capacities in most countries, as often the same human resources are spread across clinical management and outbreak response activities including vaccine rollout. The recent increase in cases reported in most regions has added to the healthcare workload and aggravated shortages of resources and the capacity to care for both those with COVID-19 and patients with other illnesses; over 90% of countries have reported some level of service disruptions and almost 40% have reported disruptions to essential primary health care services.

Infection prevention and control (IPC) and PHSM have proven to be critical in mitigating and limiting transmission and deaths due to COVID-19. The use of PHSM must be continuously monitored and adjusted, especially in the context of VOCs, to account for the intensity of transmission as well as the capacity of the health system at both national and sub-national levels. While reports confirm that most people continue to support PHSM as part of national COVID-19 response strategies, pandemic fatigue is occurring, undermining the impact of PHSM on transmission. In some countries, a lack of trust in government responses and increasing

frustration and uncertainty about the duration of the pandemic, coupled with the economic impacts of the response to COVID-19, have led to protests against PHSM.

The cornerstone of treatment for COVID-19 remains early detection and clinical assessment along with the use of oxygen and systemic corticosteroid therapy for those with severe or critical COVID-19. Markets for personal protective equipment (PPE), PCR tests, and medical oxygen equipment have begun to adjust to the higher demand, and the Biomedical Consortium (part of the UN Supply Chain) continues to support the scale-up of oxygen supply in under-resourced settings, where supply chains remain vulnerable to manufacturing and transport shutdowns/restrictions. The supply chain network, however, continues to face constraints in the availability of containers and ships, adding challenges in maintaining the cold-chain requirements of COVID-19 vaccines from production to administration.

As of 12 April 2021, four vaccines have received Emergency Use Listing by WHO. A total of 781 million doses of COVID-19 vaccines have been administered in 196 economies. However, 24 economies (including 12 from the African Region and seven from the Western Pacific Region) have not yet started vaccination. The current uneven and inequitable access and distribution of COVID-19 vaccines is exacerbating global inequalities, which coupled with the emergence of VOCs, risks prolonging the pandemic.

With a COVAX target of 20-30% population coverage with a single vaccine dose by the end of the year, and considering that the proportion of the population with immunity acquired through infection is likely less than 25%, much of the global population is still susceptible to infection. Additionally, the degree and duration of immunity conferred by natural infection, COVID-19 vaccination or the combination of both are still being investigated, and some studies suggest that those who receive vaccines may still transmit SARS-CoV2 infection to susceptible contacts. While global vaccine acceptance generally remains high, country variations have been observed due to a multitude of reasons, including exposure to misinformation as well as the attitudes of local healthcare professionals, who can play an important role in building or undermining vaccine confidence.

While our understanding of the SARS-CoV-2 virus and the complex immune response triggered by it continues to grow, much still remains unknown including the effectiveness of vaccination in reducing transmission; the duration of immunity; the role of children in transmission; and the frequency and nature of post-COVID-19 condition ("long COVID"). The emergence of VOCs introduces further unknowns such as the potential for immune escape and as to how these changes in the virus affect the global epidemiology.

Special Focus: Pandemic influenza surveillance – drawing a parallel with the COVID-19 pandemic

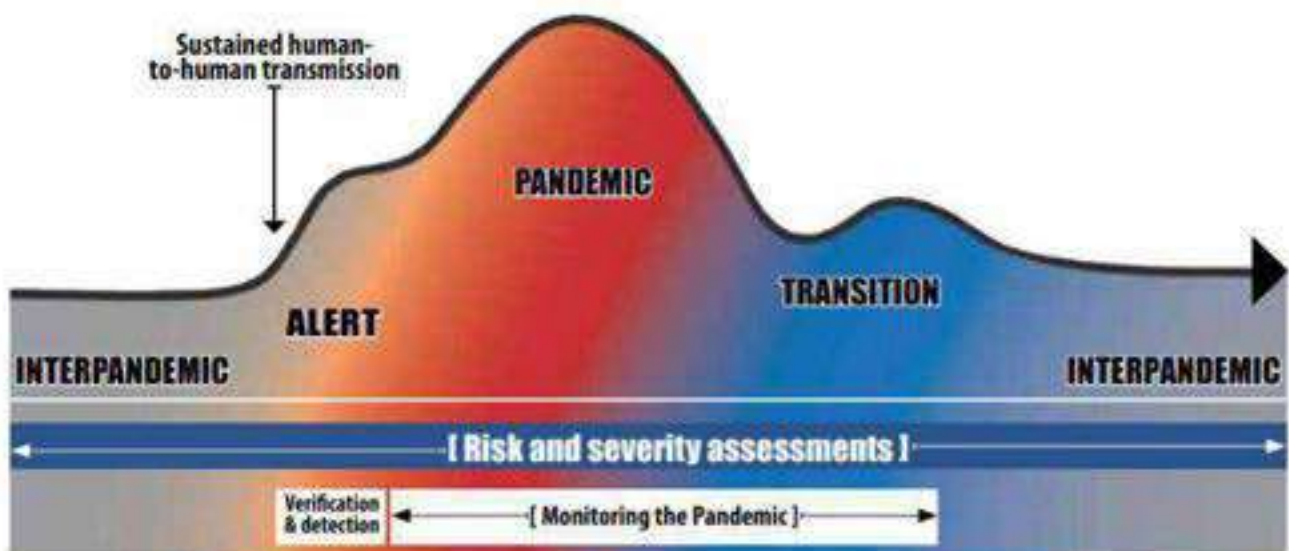

Surveillance approaches for the COVID-19 pandemic have combined the use and adaptation of existing systems as well as the establishment of new systems to meet the surveillance objectives. The Global Influenza Surveillance and Response System (GISRS) is an example of this, and has been leveraged to support the critical need to monitor trends in concurrent community circulation of both SARS-CoV-2 and seasonal influenza (see 9 March 2021 Special Focus for background information). Here, we look at parallels between surveillance approaches to influenza and the COVID-19 pandemic.

Critically, under both influenza and COVID-19 pandemic scenarios, surveillance relies upon multiple systems to:

- Verify and detect emergence and transmission,
- Monitor the geographic spread and related morbidity and mortality, and
- Assess the severity and inform development and update of vaccines and other control measures.

The WHO guidance on public health surveillance during an influenza pandemic highlight the different surveillance objectives and components needed at different phases before, during and after a pandemic (Figure 3).

Figure 3: The continuum of pandemic influenza phases (Source: WHO, 2017)

Alert Phase

In the alert phase, surveillance objectives are focused on the detection of all cases and the verification of human-to-human transmission, with an aim to interrupt virus transmission and its geographic spread and understand the virus. Event-based surveillance, active case finding and routine influenza and other respiratory virus surveillance systems (e.g., GISRS), are useful in this phase.

Event-based surveillance (EBS) is undertaken routinely by public health authorities globally to support the rapid detection and early response to signals of outbreaks of influenza and other respiratory viruses with the potential to spread from animals to humans or cause human-to-human transmission. EBS can be used for example to detect signals of clusters/outbreaks of severe respiratory disease, infections among healthcare workers, unexpected changes in routine surveillance data trends, unusually high sales of pharmaceuticals used for respiratory disease treatment, illnesses in humans linked to animal outbreaks, etc. EBS is used routinely to support COVID-19 surveillance – supporting epidemic intelligence activities for the detection and investigation of unusual epidemiological trends or changes, which combined with surveillance from other formal and informal sources, support ongoing COVID-19 situation awareness, risk assessment and an evidence-based response.

Active case finding through contact tracing and cluster/outbreak investigation are recommended for interrupting SARS-CoV-2 transmission and are similarly recommended for finding new suspected cases, documenting potential human-to-human transmission, and providing targeted interventions to decrease the risk of illness and interrupt further transmission of pandemic influenza viruses.

Pandemic Phase

Once it is clear community transmission is occurring, monitoring the situation remains critical to inform risk assessments and adjust public health interventions. During this phase, it is important to understand the virus evolution and its geographic spread, severity of disease and groups at high risk for severe disease. Surveillance activities would focus on obtaining high quality data and favour specificity over sensitivity (i.e., would not necessarily attempt to identify all cases). Wherever possible, the use and strengthening of existing surveillance systems should be favoured. Often different systems capture information for mild illness, severe illness requiring hospitalization, and mortality, which collectively provide a foundation for surveillance during the pandemic phase.

A healthcare-based surveillance approach serves as the primary approach for year-round influenza surveillance and is considered an essential surveillance approach for COVID-19 as well. During periods of heightened surveillance, other community-based case investigation and surveillance activities serve to provide additional epidemiological information.

- *Sentinel surveillance:* Existing influenza surveillance systems that use a sentinel approach emphasize collecting quality data for epidemiological and virological surveillance from a limited number of surveillance sites. Sentinel healthcare facilities are chosen based on representativeness, feasibility, and sustainability. The use of strict case definitions and testing all or a subset of cases is for surveillance purposes and not for case management or outbreak investigation. During a pandemic, ongoing sentinel surveillance aids in tracking trends; geographical spread; impact of response measures; transmission and virus characteristics, including the evolution and emergence of variants; and vaccine effectiveness. A sentinel approach to monitoring COVID-19 is recommended as a complementary approach to comprehensive surveillance at present and many countries use existing sentinel influenza surveillance systems to monitor trends in COVID-19 activity and virus characteristics.
- *Non-sentinel surveillance:* Influenza virological surveillance also relies on non-sentinel surveillance, where specimens may be collected from non-sentinel sites and where the results are more often used for clinical management and diagnostics. Compared to sentinel surveillance, information coming from non-sentinel surveillance is often not as detailed, and the cases selected for testing may not meet standard case definitions.
- *Universal surveillance:* Many countries perform universal surveillance for influenza and other respiratory pathogens, often relying on electronic health record data to collect information on all patients seeking care for an influenza-like illnesses (ILI) or severe acute respiratory illness (SARI), or individuals with a suspected or confirmed laboratory diagnosis of a notifiable respiratory pathogen (including influenza or COVID-19), to either supplement or replace sentinel surveillance. Currently [COVID-19 surveillance](#) aims to capture data from any and all COVID-19 cases, no matter where they are diagnosed.
- *Mortality surveillance:* Many countries monitor influenza-related mortality through surveillance of influenza-related deaths (using death certificates) or through statistical analysis of excess mortality attributed to influenza. The regular counting of COVID-19 deaths on a daily or weekly basis is currently recommended as part of COVID-19 surveillance mortality monitoring, including through death certificates. While not commonly done during influenza epidemics, more frequent collection and reporting of influenza-related deaths may be warranted during the pandemic phase.

- *Other sources:*

- It is estimated that around half of individuals infected with influenza do not seek healthcare for their illness.¹ Participatory surveillance for ILI involves the ongoing collection of self-reporting of symptoms from a voluntary cohort of participants who may not seek healthcare for their illness and complements data from healthcare-based surveillance systems. Some countries are also adapting current participatory surveillance systems or developing new ones for monitoring COVID-19.
- Special studies and modelling can generate information on transmission dynamics, risk and severity during a pandemic. Work done since the 2009 influenza pandemic as part of pandemic influenza preparedness activities have informed the COVID 19 response.
- Sero-epidemiological and transmission study protocols developed for use in a future influenza pandemic were immediately updated for use in the COVID-19 pandemic.

Reporting of data to WHO

Current [public health guidance](#) recommends SARS-CoV-2 infections to be nationally notifiable, with case-based reporting on a voluntary basis, and detailed aggregated data reporting requested on a weekly basis to WHO.

During further influenza pandemics, similar reporting requirements may be recommended initially. As the pandemic continues, countries would shift towards monitoring the situation, and the consistent and timely reporting of routine aggregated influenza data to regional and global WHO platforms may shift to weekly reporting of routine influenza surveillance data. It remains critical to draw lessons and sustain the momentum of the COVID-19 response to further strengthen and standardize both local and global surveillance systems to enable a robust approach to future pandemics caused by influenza and other pathogens.

Special Focus: Update on SARS-CoV-2 Variants

WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they impact public health and social measures (PHSM). Systems have been established to detect “signals” of potential variants of concern (VOCs) or variants of interest (VOIs) and assess these based on the risk posed to global public health (see also [working definitions](#)). National authorities may choose to designate other variants of local interest/concern. Detailed information on currently circulating VOCs and VOIs is available in previously published editions of the [Weekly Epidemiological Update](#). Here we provide a brief update on the geographical distribution of the three VOCs as of 20 April 2021, as well as an update on detected VOIs (Table 2).

As surveillance activities to detect SARS-CoV-2 variants are strengthened at local and national levels, including by strategic genomic sequencing, the number of countries/areas/territories (hereafter countries) reporting VOCs and VOIs has continued to increase. Since our last update on 13 April, VOC 202012/01 has been detected in five additional countries, variant 501Y.V2 in five additional countries, and variant P.1 has been reported in two additional countries. As of 20 April, a total 137 countries have reported VOC 202012/01 (Figure 4), 85 countries variant 501Y.V2 (Figure 5), and 52 countries variant P.1 (Figure 6) – see also Annex 2. The information presented here should be interpreted with due consideration of surveillance limitations, including differences in sequencing capacities and prioritization of samples for sequencing between countries.

WHO recommendations

The chances of SARS-CoV-2 mutating increases with its frequency of human and animal infections. Hence, reducing transmission of SARS-CoV-2 through established disease control methods as well as avoiding introductions into animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2 and its variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of PHSM and infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities. Authorities are also encouraged to strengthen surveillance and sequencing capacities and apply a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local context, and the detection of unusual events.

WHO regional overviews

African Region

The Africa Region reported over 54 000 new cases and over 1100 new deaths, a 7% and a 14% increase respectively compared to the previous week. The number of weekly cases continues to fluctuate over the last eight weeks, with no clear trend, while weekly deaths increased last week reflecting a large increase in deaths reported by South Africa. The highest numbers of new cases were reported from Ethiopia (12 981 new cases; 11.3 new cases per 100 000 population; a 7% decrease), South Africa (8153 new cases; 13.7 new cases per 100 000; a 35% increase), and Kenya (6103 new cases; 11.3 new cases per 100 000; a 14% decrease).

The highest numbers of new deaths were reported from South Africa (455 new deaths; 0.8 new deaths per 100 000 population; a 51% increase), Ethiopia (182 new deaths; 0.2 new deaths per 100 000; a 13% decrease), and Kenya (133 new deaths; 0.2 new deaths per 100 000; a 7% increase).

Region of the Americas

The Region of the Americas reported over 1.5 million new cases and over 39 000 new deaths, a 7% and an 8% increase respectively compared to the previous week. The region has reported an overall increasing trend in new cases for the last eight weeks and new deaths for the last five weeks. The highest numbers of new cases were reported from the United States of America (477 778 new cases; 144.3 new cases per 100 000; a 2% increase), Brazil (459 281 new cases; 216.1 new cases per 100 000; a 1% decrease), and Argentina (160 747 new cases; 355.7 new cases per 100 000; a 29% increase).

The highest numbers of new deaths were reported from Brazil (20 031 new deaths; 9.4 new deaths per 100 000; a 2% decrease), the United States of America (5146 new deaths; 1.6 new deaths per 100 000; a 1% decrease), and Mexico (4673 new deaths; 3.6 new deaths per 100 000; a 48% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 386 000 new cases and over 5400 new deaths, a 6% and a 23% increase respectively compared to the previous week. The upward trend in cases and deaths reported since February 2021 continues, with a sharper increase in new deaths the last two weeks. The highest numbers of new cases were reported from the Islamic Republic of Iran (166 367 new cases; 198.1 new cases per 100 000; a 29% increase), Iraq (52 832 new cases; 131.3 new cases per 100 000; a 6% increase), and Pakistan (34 190 new cases; 15.5 new cases per 100 000; a 3% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (2095 new deaths; 2.5 new deaths per 100 000; a 70% increase), Pakistan (765 new deaths; 0.3 new deaths per 100 000; a 21% increase), and Tunisia (482 new deaths; 4.1 new deaths per 100 000; a 59% increase).

European Region

The European Region reported over 1.6 million new cases and over 26 000 new deaths. The region reported a slight decrease in new cases (3%) for the second week in a row, a sign that transmission in the region may be slowing as the number of new deaths also decreased (3%) for the first time following a five-week increasing trend. The highest numbers of new cases were reported from Turkey (414 312 new cases; 491.2 new cases per 100 000; a 17% increase), France (233 275 new cases; 358.7 new cases per 100 000; a 12% decrease), and Germany (143 994 new cases; 173.1 new cases per 100 000; a 28% increase).

The highest numbers of new deaths were reported from Poland (3611 new deaths; 9.5 new deaths per 100 000; a 4% increase), Ukraine (2772 new deaths; 6.3 new deaths per 100 000; a 3% increase), and Italy (2753 new deaths; 4.6 new deaths per 100 000; a 14% decrease).

South-East Asia Region

The South-East Asia Region reported over 1.5 million new cases and over 9400 new deaths, a 57% and a 49% increase respectively compared to the previous week. The increasing trend in new cases and deaths, which appears to be accelerating, continued last week, with weekly cases rising sharply for the sixth consecutive week while weekly deaths rose for the fifth consecutive week. The trend in the region continues to be driven largely by the trajectory of the outbreak in India which reported the highest numbers of new cases (1 429 304 new cases; 103.6 new cases per 100 000; a 64% increase), followed by Indonesia (36 895 new cases; 13.5 new cases per 100 000; a 4% increase), and Bangladesh (36 315 new cases; 22.1 new cases per 100 000; a 25% decrease).

The highest numbers of new deaths were reported from India (7875 new deaths; 0.6 new deaths per 100 000; a 69% increase), Indonesia (885 new deaths; 0.3 new deaths per 100 000; a 26% decrease), and Bangladesh (622 new deaths; 0.4 new deaths per 100 000; a 39% increase).

Western Pacific Region

The Western Pacific Region reported over 128 000 new cases and over 1400 new deaths, a 15% increase and an 8% decrease respectively compared to the previous week. Cases increased for the sixth consecutive week, while deaths decreased after rising for three weeks, continuing to largely reflect the trajectory of deaths reported by the Philippines, the most affected country in the region. The highest numbers of new cases were reported from the Philippines (72 848 new cases; 66.5 new cases per 100 000; a 5% increase), Japan (26 426 new cases; 20.9 new cases per 100 000; a 29% increase), and Malaysia (13 742 new cases; 42.5 new cases per 100 000; a 45% increase).

The highest numbers of new deaths were reported from the Philippines (1066 new deaths; 1.0 new deaths per 100 000; a 19% decrease), Japan (240 new deaths; 0.2 new deaths per 100 000; a 49% increase), and Malaysia (49 new deaths; 0.2 new deaths per 100 000; a 40% increase).

Key weekly updates

WHO Director-General's key message

[Opening remarks at the media briefing on COVID-19](#) – 19 April 2021:

- More than 3 million deaths have been reported to WHO. It took 9 months to reach 1 million deaths; 4 months to reach 2 million, and 3 months to reach 3 million. Big numbers can make us numb, but each one of these deaths is a tragedy for families, communities and nations.
- Greta Thunberg has become the powerful voice of a younger generation demanding climate action. Greta announced a donation of 100 000 Euros from the Greta Thunberg Foundation in support of COVAX to provide vaccines to people in need.
- WHO has partnered with an alliance of the six largest youth development organizations in the world to form the Global Youth Mobilization, to empower young people to respond to the challenges created by the pandemic in their local communities.

Updates and publications

- [Statement on the seventh meeting of the International Health Regulations \(2005\) Emergency Committee regarding the coronavirus disease \(COVID-19\) pandemic](#)

**See [Annex : Data, table and figure notes](#)

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common

exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 11 April 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: SARS-CoV-2 variants](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Globally, new COVID-19 cases rose for a seventh consecutive week, with over 4.5 million new cases reported in the last week (Figure 1). The number of new deaths increased for the fourth consecutive week, increasing by 7% compared to last week, with over 76 000 new deaths reported. The largest increases in case incidence were observed in the South-East Asia (most notably in India) and the Eastern Mediterranean regions (Table 1). All regions, except for the African Region and the Americas, reported increases in the number of deaths, with the largest increase of 189% from the Western Pacific Region (largely driven by a steep increase in new deaths in the Philippines) followed by 47% in South-East Asia.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 11 April 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from India (873 296 new cases; 70% increase), the United States of America (468 395 new cases; 5% increase), Brazil (463 092 new cases; 8% decrease), Turkey (353 281 new cases; 33% increase), and France (265 444 new cases; 9% increase).

Special Focus: Update on SARS-CoV-2 Variants

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available. Further information on the background of the variants of interest (VOIs) and variants of concern (VOCs) is available from previously published editions of the [Weekly Epidemiological Update](#). Here we provide an update on the geographical distribution, and emerging evidence surrounding impacts of VOCs on COVID-19 epidemiology, vaccines and diagnostics. We also update on a recent global consultation, and emerging VOIs.

The number of countries reporting VOCs continue to increase (Table 2, Figures 3, 4 and 6, Annex 2). This information should be interpreted with due consideration of limitations of ongoing surveillance, including but not limited to differences between countries in sequencing capacity and which samples are prioritized for sequencing. WHO continues to advocate for strengthening surveillance and sequencing capacity, and a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants; based on the local epidemiological situation and capacity, and the detection of unusual events.

On 29 March 2021, WHO convened a Global Consultation on a Decision Framework for Assessing the Impact of SARS-CoV-2 VOCs on Public Health Interventions. This was the first global forum of stakeholders to outline the global risk assessment and framework, including critical steps for the detection, monitoring, and assessment of SARS-CoV-2 variants, and to provide an overview of the available evidence on current VOCs and their impact on public health interventions. Using COVID-19 vaccines as an example, WHO and partners reviewed potential decision-making processes with respect to analysing the impact of VOCs, evaluating and modifying vaccines, and issuing policy recommendations. While the existing COVID-19 vaccines are still effective against VOCs, the consultation provided the opportunity to consider the overall process for making changes to vaccines, should they be needed. Following the consultation, WHO is working with partners to further define the global risk monitoring and assessment framework for SARS-CoV-2 variants to fully elaborate decision-making processes, including recommending any changes to vaccine composition, and triggers for such decision making. The meeting report will be published in the coming weeks. A follow up consultation is tentatively planned for June 2021.

Table 2: Overview of emerging information on key variants of concern, as of 13 April 2021*

Nextstrain clade	20I/501Y.V1	20H/501Y.V2†	20J/501Y.V3
PANGO lineage	B.1.1.7	B.1.351	B.1.1.28.1, alias P.1†
GISAID clade	GR	GH	GR
Alternate names	VOC 202012/01†	VOC 202012/02	VOC 202101/02
First detected by	United Kingdom	South Africa	Brazil / Japan
Earliest sample(s)	20 September 2020	Early August 2020	December 2020
Key spike mutations	H69/V70 deletion; Y144 deletion; N501Y; A570D; and P681H	L242/A243/L244 deletion; K417N; E484K; N501Y	K417T; E484K; N501Y
Common mutation	S106/G107/F108 deletion in non-structural protein 6 (nsp6)		
Transmissibility	Increased (43%-90%) ¹ , increased secondary attack rate [11% (95%CI: 10.9-11.2%) among closer contacts] ²	Increased [1.50 (95% CI: 1.20-2.13) times more transmissible than previously circulating variant ^{3, 4}	Increased, more transmissible than previous circulating variants ⁵
Severity	Possible increased risk of hospitalization ⁶ , severity and mortality ⁷ . Other studies showing limited impact/mixed findings ^{1, 8, 9}	Possible increased risk of in-hospital mortality by 20% ^{4,10}	Under investigation, limited impact ⁵
Assessment of potential reinfection/breakthrough	Slight reduction in neutralization capacity but overall neutralizing titers still remained above the levels expected to confer protection ¹¹	Decreased neutralization capacity, suggesting potential increased risk of reinfection ^{3, 12, 13}	Decreased neutralization capacity, reinfections reported ^{14, 15}
Potential impacts on vaccines	<ul style="list-style-type: none"> No or minimal impact on post-vaccine neutralization by Moderna, Pfizer-BioNTech, Oxford-AstraZeneca, Novavax, Bharat, Gamaleya, and Sinopharm vaccines^{11, 16-30,31}; however there is some evidence of more substantial loss for AstraZeneca.³² Bharat, Gamaleya, Sinopharm, and Sinovac vaccines have each been evaluated by single studies reporting no significant reduction in neutralization.^{33, 34} No significant change in prevention of disease by Oxford-AstraZeneca, Novavax, and Pfizer³⁵⁻³⁷ Evidence for prevention of infection limited. Reduced effect reported for Oxford-AstraZeneca.³² 	<ul style="list-style-type: none"> Post-vaccine neutralization reductions from several from studies range from minimal to substantial for Moderna and Pfizer. Substantial reductions have been found for the Oxford-AstraZeneca product.^{29, 40} Minimal to modest reductions have been found for Sinopharm. A single study found modest reduction for Sinovac. Single studies found more substantial reduction for Novavax and Gamaleya. Efficacy against disease was retained, but somewhat lower, in South Africa for the Novavax and Janssen vaccines when 501Y.V2 was dominant compared to settings without this variant.^{41, 42} In a small study, AstraZeneca vaccine did not demonstrate vaccine efficacy against mild-moderate COVID-19 disease, with wide confidence intervals, while efficacy against severe disease was not assessed and is undetermined.^{43, 44} Information regarding vaccine impact on asymptomatic infection by 501Y.V2 remains a gap. 	<ul style="list-style-type: none"> Limited to modest reduction in post-vaccine neutralization by Oxford-AstraZeneca, Moderna and Pfizer vaccines; however there is some evidence of more substantial reduction.^{18, 21, 28, 29, 38, 45, 46} Preliminary suggestion of loss of neutralization following vaccination with Sinovac⁴⁷ Preliminary vaccine effectiveness of Sinovac in setting of P.1 was estimated in Brazil⁶
Potential impacts on diagnostics	S gene target failure (SGTF). No impact on Ag RDTs observed ⁴⁸	None reported to date	None reported to date
Countries reporting cases (newly reported since the last update**	132 (2)	82 (2)	52(7)

†While work is ongoing to establish standardized nomenclature for key variants, these are the names by which WHO will refer to them in this publication.

*Generalized findings as compared to non-VOC viruses. Based on emerging evidence from multiple countries, including nonpeer reviewed preprint articles and reports from public health authorities and researchers – all subject to ongoing investigation and continuous revision.

**Includes official and unofficial reports of VOCs detections in countries/territories/areas.

Variant VOC 202012/01

Since our last update on 30 March, VOC 202012/01 has been detected in two additional countries. As of 13 April, a total of 132 countries across all six WHO regions have reported cases of this variant (Figure 3).

Several studies have shown increased transmissibility (including secondary attack rates), severity and mortality associated with VOC 202012/01 compared to non-VOC variants.^{1, 6-9, 49-53} As mentioned in earlier publications, the likelihood of infection upon contact (secondary attack rate) is higher in people infected with VOC202012/01 than other variants. A recent technical briefing by Public Health England estimated the secondary attack rates to be 11% (95%CI: 10.9%-11.2%) higher among close contacts of cases who have not travelled between 5 January to 7 March 2021. Among the cases who travelled, secondary attack rates were estimated to be 1.9% (95% CI: 1.7%-2.2%); of note this population was not restricted to only close contacts and included several categories such as contacts on a plane linked by additional contact tracing.²

A recently published study which used datasets from several European countries and the United States of America estimated that VOC 202012/01 has a 43–93% higher reproduction number (95% CI: 38–130%) than previously circulating variants.¹ The study also assessed the severity of disease, but differing from other studies, suggested no clear evidence increased severity associated with VOC 202012/01; however, these estimates should be interpreted with caution given delays between infection and hospitalization or death (models were fitted through to 24 December 2020). Additionally, it has been shown that higher rates of transmission and case incidence may lead to more hospital admissions and strain on health systems – potentially impacting on patient outcomes. Two other recently published peer reviewed studies (an ecological study and a hospital-based cohort study) found no evidence of an association between VOC202012/01 and severe disease or death^{8,9}; again, the generalizability to these findings require further review against other evidence. Collectively, these studies highlighted the need for further research to better understand the impact of VOC 202012/01.

There is a growing body of evidence on vaccine-induced neutralizing antibody activity against VOC 202012/01, including for AstraZeneca, Moderna, Pfizer, Novavax, Bharat, Gamaleya, and Sinopharm vaccines.^{11, 16-30 31} As noted in the [Weekly epidemiological Update published on 23 March](#), the findings support that neutralizing activity is largely sustained against this variant. A recent evaluation of CD8+ T-cell from convalescent sera supports the likelihood of maintaining recognition of this variant; however, vaccine induced T-cell responses were not directly evaluated.⁵⁵ Evidence for vaccine protection against disease is available from randomized control trials and observational studies (AstraZeneca and Pfizer vaccines) and early evidence on prevention of infection of this variant by the AstraZeneca vaccine.⁵⁵

Figure 3. Countries, territories and areas reporting SARS-CoV-2 VOC 202012/01 as of 13 April 2021

Variant 501Y.V2

Since the last update on 30 March, 501Y.V2 has been reported from two additional countries – totalling 82 countries across all six WHO regions (Figure 4).

Investigations from a recent study⁵⁶ showed five imported cases of variant 501Y.V2 was responsible for 14 transmission chains and a total 36 cases in France. It suggested that epidemiological characteristics, such as incubation period and transmissibility, seemed comparable to those described in China⁵⁷⁻⁵⁹ before the emergence of the 501Y.V2 variant. This study also established that the secondary attack rate (confirmed or probable cases) was estimated at 76.9% and the tertiary attack rate was estimated at 73.3%. The study highlights that the lack of tertiary transmission outside of the personal sphere suggests that distancing and barrier measures were effective.

Reductions in neutralizing antibody activity against 501Y.V2 induced by vaccines or natural infection compared with wild-type (non-VOC) variants, have been documented in a substantial number of studies.^{3, 18, 21, 24, 25, 27-29, 40, 46, 60, 61} Findings from four recent studies report substantial reductions in neutralizing antibody activity for Moderna (9.7-fold reduction), Pfizer-BioNTech (14-fold and 8.8-fold reductions)³⁰, Novavax (14.5-fold reduction) and Gamaleya (6.8-fold reduction) vaccines.^{22, 24, 61} However, some studies report smaller reductions for Moderna and Pfizer-BioNTech vaccines.^{21, 26, 40} Another recent study found 2.4 to 3.3-fold reductions in neutralizing activity induced by the Sinovac and Sinopharm vaccines.³⁴ Adding to the previously cited T-cell analyses from the [30 March update](#), which suggested a likely maintenance of function, a further analysis of CD8+ T-cell responses from convalescent sera which also support the likely retention of function.^{55, 62}

Figure 4. Countries, territories and areas reporting SARS-CoV-2 501Y.V2 as of 13 April 2021

Variant P.1

Since our last update, variant P.1 has been reported in seven additional countries. As of 13 April, this variant is reported in 52 countries across all six WHO regions (Figure 5).

Genomic surveillance and modelling studies based in Brazil suggest higher transmissibility of the P.1 variant when compared to Brazilian non-P.1 lineages.^{15, 63, 64} Moreover, case fatality rates in Brazil increased in people older than 20 years in February 2021, when compared to January 2021, suggesting a potential association between P.1 and more severe disease.⁶⁵ Akin to similar observations with other VOCs elsewhere, it will be important to disentangle changes in disease severity from impacts of increased transmissibility/high incidence adding pressures to health systems and adversely impacting patient outcomes.

A recent study carried out in Italy in settings where both P.1 and VOC 202012/01 were co-circulating at significant levels highlighted that the P.1 variant was outcompeted by VOC 202012/01, which rapidly dominated in the majority of regions. The same study also highlighted potential cross-protection across variants.⁶⁶

In Brazil, the proportion of variant P.1 increased from 28% of specimens collected in January 2021 to 73% in March 2021, based on the data generated from the Fiocruz Genomic Network and GISAID (Figure 5).⁶⁷ By geographic region of specimen collection, the proportion of variant P.1 was higher in the South east and North regions, which includes Amazonas State, compared to other regions.

Figure 5. Proportion of lineages of SARS-CoV-2 identified in Brazil by month of sampling, February 2020 – March 2021

Several studies have measured the neutralization of variant P.1 by sera from those vaccinated with Pfizer, Moderna, AstraZeneca or Sinovac, including a recent report from the phase III randomized control trial of Sinovac in Brazil reporting seroconversion.^{17, 21, 25, 26, 28, 29, 46, 68, 69} Based on these findings, the neutralization activity was reduced by 1.7 to 10-fold depending on the vaccine and individuals; for some vaccines, there was substantial variability in results across studies. One T-cell study concluded that responses against this variant were largely preserved and a recent CD8+ T-cell study of convalescent sera also inferred likely retention of activity.⁵⁵ Preliminary clinical outcome data are currently limited to a recent matched test-negative case-control study of healthcare workers in Manaus, Brazil at a time when P.1 was prevalent. It found the Sinovac vaccine to be 49.6% effective against symptomatic COVID-19 and 35.1% effective against asymptomatic infection, though these findings have not yet been peer-reviewed.⁷⁰

Figure 6. Countries, territories and areas reporting SARS-CoV-2 P.1 variant as of 13 April 2021

Emerging variants of interest (VOIs)

All viruses, including SARS-CoV-2, change over time resulting in the emergence of new variants, most without a direct benefit to the virus or other public health impacts. WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they impact on public health and social measures (PHSM). Systems have been established to detect “signals” of potential variants of interest or concern, as well as unusual events potentially associated with a variant, and assess these based on the risk posed to global public health (see also [working definitions](#)). A number of such signals are currently under assessment, and as new VOIs or VOCs are determined, WHO is committed to highlighting these to support prioritization for further monitoring and assessment. Table 3 summarises assessed and designated VOIs as of 13 April 2021. National authorities may choose to designate other variants of local interest/concern as every local situation is unique, with different variants circulating, requiring surveillance and response systems to adapt to their local epidemiological situation.

Table 3: Overview of variants of interest (VOIs), as of 13 April 2021*

Nextstrain clade	PANGO lineage	GISAID clade	Alternate names	First detected by	Earliest samples	Key spike mutations
20C	B.1.525	G/484K.V3	-	United Kingdom and Nigeria	Dec 2020	H69-V70 deletion; Y144 deletion; Q52R; E484K; Q677H; D614G; and F888L

WHO recommendations

The potential for virus mutation increases with the frequency of human and animal infections. Therefore, reducing transmission of SARS-CoV-2 by using established disease control methods as well as avoiding introductions to animal populations, are critical aspects to the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critically important to curb the spread of SARS-CoV-2, including newly reported variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of physical distancing and other PHSM, as well as infection prevention and control (IPC) measures in health facilities, has been effective in reducing COVID-19 case incidence, hospitalizations and deaths. Findings from new studies evaluating transmission, severity and impact on medical countermeasures will continue to help inform PHSM and IPC measures employed by Member States. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities, including epidemiological surveillance, strategic testing, and systematic sequencing of SARS-CoV-2 where feasible.

WHO regional overviews

African Region

The African Region reported over 50 000 new cases and over 1000 new deaths, a 14% and a 5% decrease respectively compared to the previous week. Weekly cases incidence has fluctuated since late February 2021; however, deaths have continued an overall downward trend. The highest numbers of new cases were reported from Ethiopia (13 944 new cases; 12.1 new cases per 100 000 population; a 4% decrease), Kenya (7107 new cases; 13.2 new cases per 100 000; a 19% decrease), and South Africa (6026 new cases; 10.2 new cases per 100 000; a 14% decrease).

The highest numbers of new deaths were reported from South Africa (302 new deaths; 0.5 new deaths per 100 000 population; a 1% decrease), Ethiopia (210 new deaths; 0.2 new deaths per 100 000; a 38% increase), and Kenya (124 new deaths; 0.2 new deaths per 100 000; a 22% increase).

Region of the Americas

The Region of the Americas reported over 1.4 million new cases and over 36 000 new deaths, a 5% increase and 2% decrease respectively compared to the previous week. Cases have overall gradually increased since mid-February 2021. The highest numbers of new cases were reported from the United States of America (468 395 new cases; 141.5 new cases per 100 000; a 5% decrease), Brazil (463 092 new cases; 217.9 new cases per 100 000; an 8% decrease), and Argentina (124 728 new cases; 276.0 new cases per 100 000; a 52% increase).

The highest numbers of new deaths were reported from Brazil (20 512 new deaths; 9.7 new deaths per 100 000; a 3% decrease), the United States of America (5173 new deaths; 1.6 new deaths per 100 000; a 31% decrease), and Mexico (3166 new deaths; 2.5 new deaths per 100 000; a 6% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 364 000 new cases and just under 4400 new deaths, a 22% and a 19% increase respectively compared to the previous week. Upward trends in cases and deaths reported since February have continued, with steep increases this week compared to the previous week. The highest numbers of new cases were reported from the Islamic Republic of Iran (128 684 new cases; 153.2 new cases per 100 000; a 75% increase), Iraq (49 955 new cases; 124.2 new cases per 100 000; a 22% increase), and Jordan (35 520 new cases; 348.1 new cases per 100 000; a 21% decrease).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (1233 new deaths; 1.5 new deaths per 100 000; a 78% increase), Pakistan (632 new deaths; 0.3 new deaths per 100 000; a 17% increase), and Jordan (578 new deaths; 5.7 new deaths per 100 000; a 12% decrease).

European Region

The European Region reported over 1.6 million new cases and over 26 000 new deaths, a 4% decrease and a 7% increase respectively compared to the previous week. The decrease in cases this week was reported after six consecutive weeks of increases since late February. Deaths continued to increase for a fifth week. The highest numbers of new cases were reported from Turkey (353 281 new cases; 418.9 new cases per 100 000; a 33% increase), France (265 444 new cases; 408.1 new cases per 100 000; a 9% increase), and Poland (136 089 new cases; 358.5 new cases per 100 000; a 27% decrease).

The highest numbers of new deaths were reported from Poland (3480 new deaths; 9.2 new deaths per 100 000; a 14% increase), Italy (3219 new deaths; 5.4 new deaths per 100 000; a 5% increase), and Ukraine (2681 new deaths; 6.1 new deaths per 100 000; a 13% increase).

South-East Asia Region

The South-East Asia Region reported over 965 000 new cases and over 6300 new deaths, a 63% and a 47% increase respectively compared to the previous week. There were steep increases in both cases and deaths, and the highest number of weekly cases was reported in the Region since the beginning of the pandemic. The highest numbers of new cases were reported from India (873 296 new cases; 63.3 new cases per 100 000; a 70% increase), Bangladesh (48 660 new cases; 29.5 new cases per 100 000; a 26% increase), and Indonesia (35 344 new cases; 12.9 new cases per 100 000; a 1% decrease).

The highest numbers of new deaths were reported from India (4652 new deaths; 0.3 new deaths per 100 000; a 51% increase), Indonesia (1201 new deaths; 0.4 new deaths per 100 000; a 37% increase), and Bangladesh (448 new deaths; 0.3 new deaths per 100 000; a 30% increase).

Western Pacific Region

The Western Pacific Region reported over 111 000 new cases and over 1500 new deaths, a 6% and a 189% increase respectively compared to the previous week. For a fifth consecutive week, the number of cases increased. The sharp rise in deaths were attributed to steep increases in deaths in the Philippines. The highest numbers of new cases were reported from the Philippines (69 164 new cases; 63.1 new cases per 100 000; a 3% decrease), Japan (20 536 new cases; 16.2 new cases per 100 000; a 28% increase), and Malaysia (9507 new cases; 29.4 new cases per 100 000; a 6% increase).

The highest numbers of new deaths were reported from the Philippines (1321 new deaths; 1.2 new deaths per 100 000; a 400% increase), Japan (161 new deaths; 0.1 new deaths per 100 000; a 15% decrease), and Malaysia (35 new deaths; 0.1 new deaths per 100 000; similar to the previous week).

Key weekly updates

WHO Director-General's key message

[Opening remarks at the media briefing on COVID-19](#) – 9 April 2021:

- A total of 196 countries have started vaccination.
- More than 700 million vaccine doses have been administered globally, but over 87% have gone to high income or upper middle-income countries, while low-income countries have received just 0.2%.
- WHO, Gavi, CEPI and other COVAX partners are working on several options for accelerating production and supply.

World Health Day

- [World Health Day 2021: Building a fairer, healthier world](#)
- [For World Health Day, 7 April 2021, WHO issued five calls for urgent action to improve health for all](#)
- [“Give a Breath for Health” campaign launched on World Health Day to kickstart global effort for purchasing oxygen and other life-saving supplies and therapeutics for COVID-19 patients starting in the Americas](#)

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 4 April 2021, 10 am CET

In this edition:

- [Global overview](#)
- [WHO regional overviews](#)

Erratum: Variants of Concern (VOCs) were incorrectly reported for Mauritania in the previous publications on 23 March and 30 March 2021. The country has not reported any VOCs to date.

Global overview

Globally, new COVID-19 cases rose for a sixth consecutive week, with over 4 million new cases reported in the last week (Figure 1). The number of new deaths also increased by 11% compared to last week, with over 71 000 new deaths reported. The largest increases in case incidence were observed in the South-East Asia (most notably in India) and the Western Pacific regions (Table 1). All regions, except for the African Region, reported increases in the number of deaths, with the largest increase of 46% from the South-East Asia Region.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 4 April 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from India (513 885 new cases; 38% increase), Brazil (505 668 new cases; 5% decrease), the United States of America (444 756 new cases; 5% increase), Turkey (265 937 new cases; 43% increase), and France (244 607 new cases; 4% decrease).

WHO regional overviews

African Region

The Region reported around 59 000 new cases and 1000 new deaths last week, a 6% and 20% decrease respectively compared to the previous week. The highest numbers of new cases were reported from Ethiopia (14 517 new cases; 12.6 new cases per 100 000 population; a 10% increase), Kenya (8747 new cases; 16.3 new cases per 100 000; a 5% decrease), and South Africa (7035 new cases; 11.9 new cases per 100 000; an 8% decrease).

The highest numbers of new deaths were reported from South Africa (306 new deaths; 0.5 new deaths per 100 000 population; a 46% decrease), Ethiopia (152 new deaths; <0.1 new deaths per 100 000; a 11% increase), and Kenya (102 new deaths; 0.2 new deaths per 100 000; a 13% decrease).

Region of the Americas

The Region reported over 1.3 million new cases and over 37 000 new deaths, a 3% and a 15% increase respectively compared to the previous week. Overall, there has been an increasing trend in weekly case incidence over the last six weeks. The highest numbers of new cases were reported from Brazil (505 668 new cases; 237.9 new cases per 100 000; a 5% decrease), the United States of America (444 756 new cases; 134.4 new cases per 100 000; a 5% increase), and Argentina (82 102 new cases; 181.7 new cases per 100 000; a 46% increase).

The highest numbers of new deaths were reported from Brazil (21 094 new deaths; 9.9 new deaths per 100 000; a 26% increase), the United States of America (7536 new deaths; 2.3 new deaths per 100 000; an 8% increase), and Mexico (2992 new deaths; 2.3 new deaths per 100 000; an 18% decrease).

Eastern Mediterranean Region

The Region reported over 297 000 new cases and about 3700 new deaths, a 10% and a 7% increase respectively compared to the previous week. Both cases and deaths are on an upward trajectory with new cases increasing for the past eight weeks. The highest numbers of new cases were reported from the Islamic Republic of Iran (73 471 new cases; 87.5 new cases per 100 000; a 38% increase), Jordan (44 742 new cases; 438.5 new cases per 100 000; a 19% decrease), and Iraq (41 043 new cases; 102.0 new cases per 100 000; an 9% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (691 new deaths; 0.8 new deaths per 100 000; an 18% increase), Jordan (658 new deaths; 6.4 new deaths per 100 000; a 4% decrease), and Pakistan (539 new deaths; 0.2 new deaths per 100 000; a 50% increase).

European Region

After reporting a progressive increase in weekly cases for five weeks, the number of new cases reported this past week is similar to that reported in the previous week, with over 6.2 million new cases reported. The number of new deaths, however, has continued to increase for the past four weeks, with 24 000 new deaths reported. The highest numbers of new cases were reported from Turkey (265 937 new cases; 315.3 new cases per 100 000; a 43% increase), France (244 607 new cases; 374.7 new cases per 100 000; a 4% decrease), and Poland (187 551 new cases; 495.6 new cases per 100 000; a 3% decrease).

The highest numbers of new deaths were reported from Italy (3068 new deaths; 5.1 new deaths per 100 000; a 2% increase), Poland (3057 new deaths; 8.1 new deaths per 100 000; an 18% increase), and the Russian Federation (2634 new deaths; 1.8 new deaths per 100 000; a 3% decrease).

South-East Asia Region

The Region reported over 592 000 new cases and 4300 new deaths, a 36% and a 46% increase respectively compared to the previous week. Case incidence rates have risen markedly through March, with a sharp increase in the past three weeks. The number of new deaths continued to increase in the past three weeks with a steep increase reported in past one week. India contributed 87% of new cases and 71% of new deaths in the Region in the past week. The highest numbers of new cases were reported from India (513 885 new cases; 37.2 new cases per 100 000; a 38% increase), Bangladesh (38 471 new cases; 23.4 new cases per 100 000; a 67% increase), and Indonesia (35 522 new cases; 13 new cases per 100 000; a 2% decrease).

The highest numbers of new deaths were reported from India (3071 new deaths; 0.2 new deaths per 100 000; a 71% increase), Indonesia (878 new deaths; 0.3 new deaths per 100 000; a 4% decrease), and Bangladesh (344 new deaths; 0.2 new deaths per 100 000; a 71% increase).

Western Pacific Region

The Region reported over 106 000 new cases and over 500 new deaths, a 25% and a 5% increase respectively compared to the previous week. A steep increase in the number of new cases has been observed over the past four weeks. The highest numbers of new cases were reported from the Philippines (71 606 new cases; 65.3 new cases per 100 000; a 27% increase), Japan (16 018 new cases; 12.7 new cases per 100 000; a 43% increase), and Malaysia (8968 new cases; 27.7 new cases per 100 000; similar to the previous week).

The highest numbers of new deaths were reported from the Philippines (264 new deaths; 0.2 new deaths per 100 000; a 15% increase), Japan (190 new deaths; 0.2 new deaths per 100 000; a 13% decrease), and Malaysia (35 new deaths; <0.1 new deaths per 100 000; a 59% increase).

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 28 March 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: COVID-19 and Health and Care Workers \(HCWs\)](#)
- [Special focus: SARS-CoV-2 variants](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Globally, new COVID-19 cases rose for a fifth consecutive week, with just over 3.8 million new cases reported in the last week (Figure 1). The number of new deaths increased for the second consecutive week, increasing by 5% compared to last week, with over 64 000 new deaths reported. All regions reported an increase in the number of cases this week, with the largest increases in the South-East Asia, Western Pacific, and African Regions, all of which have been on an upward trajectory in recent weeks. All regions, except for the African Region, reported an increase in the number of deaths, with the largest increase of 21% from the South-East Asia Region, which is on its third week of an increasing trend. The European Region and the Region of the Americas continue to account for approximately 80% of all new and cumulative cases and deaths.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 28 March 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from Brazil (533 024 new cases; 5% increase), the United States of America (421 936 new cases; 13% increase), India (372 494 new cases; 55% increase), France (254 228 new cases; 24% increase), and Poland (192 441 new cases; 27% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 28 March 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 306 017 (34%)	11%	55 243 776 (44%)	32 176 (50%)	4%	1 331 419 (48%)
Europe	1 641 672 (43%)	11%	44 191 579 (35%)	23 778 (37%)	7%	954 829 (34%)
South-East Asia	437 060 (11%)	46%	14 619 886 (12%)	2 947 (5%)	21%	217 737 (8%)
Eastern Mediterranean	270 884 (7%)	3%	7 395 085 (6%)	3 428 (5%)	5%	156 891 (6%)
Africa	62 286 (2%)	22%	3 061 438 (2%)	1 340 (2%)	-6%	77 446 (3%)
Western Pacific	84 395 (2%)	32%	1 859 933 (1%)	518 (1%)	7%	31 361 (1%)
Global	3 802 314 (100%)	14%	126 372 442 (100%)	64 187 (100%)	5%	2 769 696 (100%)

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior. Regional percentages rounded to the nearest whole number; global totals may not equal 100%.

Special Focus: COVID-19 and Health and Care Workers (HCWs)

HCWs have been central to the COVID-19 response since the beginning of the pandemic. Many of their functions and roles put them at risk of exposure to hazards that can impact their working conditions as well as have impact their physical and social well-being. It is therefore critical to monitor the multidimensional factors affecting HCWs as the pandemic continues (Figure 3).

Figure 3. Multidimensional factors related to COVID-19 that impact HCWs

HCWs continue to face a range of interconnected factors that affect their mental health and stress levels which increase with irregular working hours, higher levels of exposure to illness, fear of infection with COVID-19 related to exposure, and/or lack of adequate PPE amongst others. Published studies show that the prevalence of mental health conditions among HCWs was significantly higher than other professional groups. HCWs reported a higher level of anxiety (13.0% vs. 8.5%) and depression (12.2% vs. 9.5%)¹ as compared to other groups, with insomnia as a risk factor for both. A recent study with data from six countries found that insomnia, sleeping disorders and burnout were significant risk factors for COVID-19 infection among HCWs².

As the pandemic continues, more evidence has been collected to describe the challenging working and psychosocial conditions HCWs face daily (Table 2).

¹ <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7409979/>

² <https://nutrition.bmj.com/content/early/2021/03/03/bmjnp-2021-000228>

Table 2. A selective summary of the COVID-19 impact dimension on HCWs

Dimension	Evidence
Stigma and discrimination	HCWs were at increased risk to experience stigma and bullying, adjusted odds ratio: 1.5 (95% CI 1.2 to 2.0). ³
Violence	Since the beginning of the outbreak, attacks on health care have continuously been reported and now also include incidents linked to the COVID-19 pandemic across the world. ⁴
Lack of PPE	Lack of PPE for HCWs has been observed in several countries. ^{5 6}
Strike actions	An independent analysis has identified industrial dispute and strike action in 84 Member States since February 2020; of which 38% and 29% of strikes are due to poor working conditions and lack of PPE, respectively. ⁷
Quarantine and self-isolation	In a survey of health professionals and allied employees, 24% of HCWs declared that they had to return to work while still having symptoms of COVID-19. ⁸
Other working conditions	Role of privatization in delivery of services, managerial practices in nursing homes exacerbated impact of COVID-19. ⁹

HCWs continue to play an integral role in the pandemic response. It is crucial that HCWs be adequately supported in order to ensure their physical and mental well-being.

Special Focus: Update on SARS-CoV-2 Variants

All viruses, including SARS-CoV-2, change over time resulting in the emergence of new variants, most without a direct benefit to the virus or other public health impacts. WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they impact public health and social measures (PHSM). Systems have been established to detect “signals” of potential variants of concern (VOCs) or variants of interest (VOIs), as well as unusual events potentially associated with a variant, and assess these based on the risk posed to global public health (see also [working definitions](#)). A number of such signals are currently under assessment, and as new VOCs and VOIs are determined, WHO is committed to highlighting these to support prioritization for further monitoring and assessment. National authorities may choose to designate other variants of local interest/concern as every local situation is unique, with different variants circulating, requiring surveillance and response systems to adapt to their local epidemiological situation.

Further information on the background of the variants of concern (VOCs) and variants of interest (VOIs) is available in previously published editions of the [Weekly Epidemiological Update](#). Here we provide a brief update on the geographical distribution of the three variants classified as VOCs by WHO as of 30 March 2021 as well as an update on emerging VOIs.

As surveillance activities to detect SARS-CoV-2 variant cases are strengthened at local and national levels, including systematic genomic sequencing, the number of countries reporting VOCs has continued to increase (Table 3, Figures 4-6, Annex 2). This information should be interpreted with due consideration of surveillance limitations, including but not limited to differences between countries in sequencing capacity and prioritization of samples for sequencing. WHO continues to advocate for strengthening surveillance and sequencing capacity, and a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants based on the local epidemiological situation and capacity, and the detection of unusual events.

Table 3: Overview of emerging information on variants of concern, as of 30 March 2021*

Nextstrain clade	20I/501Y.V1	20H/501Y.V2 [†]	20J/501Y.V3

WHO recommendations and working definitions of VOI and VOC

The potential for virus mutation increases with the frequency of human and animal infections. Therefore, reducing transmission of SARS-CoV-2 through established disease control methods as well as avoiding introductions to animal populations are crucial aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critical to curb the spread of SARS-CoV-2, including new variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of PHSM and infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. Findings from new studies evaluating transmission, severity and impact on medical countermeasures will continue to help inform PHSM and IPC measures employed by Member States. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities, including epidemiological surveillance, strategic testing, and systematic sequencing of SARS-CoV-2 where feasible.

WHO regional overviews

African Region

After reporting a decline in new cases for two consecutive weeks, the African Region reported a 22% increase in new cases (>62 000 cases) compared to the previous week, and over 1300 new deaths, a 6% decrease. The highest numbers of new cases were reported from Ethiopia (13 153 new cases; 11.4 new cases per 100 000 population; a 14% increase) and Kenya (9167 new cases; 17 new cases per 100 000; a 25% increase).

The highest numbers of new deaths were reported from South Africa (566 new deaths; one new death per 100 000 population; a 31% decrease) and Ethiopia (137 new deaths; <0.1 new deaths per 100 000; a 28% increase).

Region of the Americas

The Region of the Americas reported over 1.3 million new cases and over 32 000 new deaths, an 11% and 4% increase respectively compared to the previous week. Overall, there has been an increasing trend in weekly reported cases in the last five weeks. A slight increase in new deaths has been reported in the last two weeks after a decline in deaths for the six prior weeks. The highest numbers of new cases were reported from Brazil (533 024 new cases; 250.8 new cases per 100 000; a 5% increase), the United States of America (421 936 new cases; 127.5 new cases per 100 000; a 13% increase), and Peru (60 739 new cases; 184.2 new cases per 100 000; a 24% increase).

The highest numbers of new deaths were reported from Brazil (16 798 new deaths; 7.9 new deaths per 100 000; a 10% increase), the United States of America (6995 new deaths; 2.1 new deaths per 100 000; a 7% decrease), and Mexico (3643 new deaths; 2.8 new deaths per 100 000; an 8% increase).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported just under 271 000 new cases and over 3400 new deaths, a 3% and a 5% increase respectively compared to the previous week. Both cases and deaths are on an upward trajectory with new cases increasing for the past seven weeks and deaths for the past five weeks. The highest numbers of new cases were reported from Jordan (55 467 new cases; 543.6 new cases per 100 000; a 4% decrease), the Islamic Republic of Iran (53 118 new cases; 63.2 new cases per 100 000; a 2% decrease), and Iraq (37 767 new cases; 93.9 new cases per 100 000; an 8% increase).

The highest numbers of new deaths were reported from Jordan (684 new deaths; 6.7 new deaths per 100 000; a 36% increase), the Islamic Republic of Iran (584 new deaths; 0.7 new deaths per 100 000; similar to last week), and Pakistan (359 new deaths; 0.2 new deaths per 100 000; an 11% increase).

European Region

The European Region reported over 1.6 million new cases and just under 24 000 new deaths in the past week, an 11% and a 7% increase respectively compared to the previous week. The number of new cases in the Region has been steadily increasing over the past five weeks while the number of new deaths has increased for the past three weeks. The highest numbers of new cases were reported from France (254 228 new cases; 389.5 new cases per 100 000; a 24% increase), Poland (192 441 new cases; 508.5 new cases per 100 000; a 27% increase), and Turkey (186 421 new cases; 221.0 new cases per 100 000; a 47% increase).

The highest numbers of new deaths were reported from Italy (2994 new deaths; 5.0 new deaths per 100 000; an 8% increase), the Russian Federation (2710 new deaths; 1.9 new deaths per 100 000; an 8% decrease), and Poland (2584 new deaths; 6.8 new deaths per 100 000; a 22% increase).

South-East Asia Region

The South-East Asia Region reported over 437 000 new cases and just under 3000 new deaths, a 46% and a 21% increase respectively compared to the previous week. Cases in the Region have been steadily increasing over the past three weeks, with a sharp increase in the past two weeks. Almost 85% of cases in the Region over the past week were from India which reported 372 494 new cases (27 new cases per 100 000; a 55% increase). The other countries reporting the highest numbers of new cases in the Region were Indonesia (36 214 new cases; 13.2 new cases per 100 000; a 12% decrease) and Bangladesh (23 100 new cases; 14.0 new cases per 100 000; an 85% increase).

The highest numbers of new deaths were reported from India (1797 new deaths; < 0.1 new deaths per 100 000; a 57% increase), Indonesia (917 new deaths; 0.3 new deaths per 100 000; an 18% decrease), and Bangladesh (201 new deaths; <0.1 new deaths. per 100 000; a 43% increase).

Western Pacific Region

The Western Pacific Region reported over 84 000 new cases and just over 500 new deaths, a 32% and a 7% increase respectively compared to the previous week. The Region has reported a steep increase in the number of new cases over the past three weeks. The highest numbers of new cases were reported from the Philippines (56 380 new cases; 51.5 new cases per 100 000; a 43% increase), Japan (11 211 new cases; 8.9 new cases per 100 000; a 28% increase), and Malaysia (8929 new cases; 27.6 new cases per 100 000; a 4% decrease).

The highest numbers of new deaths were reported from the Philippines (229 new deaths; 0.2 new deaths per 100 000; a 40% increase), Japan (219 new deaths; 0.2 new deaths per 100 000; a 13% decrease), and the Republic of Korea (26 new deaths; <0.1 new deaths per 100 000; a 4% decrease).

Key weekly updates

WHO Director-General's key message

[Opening remarks at the media briefing on COVID-19](#) – 26 March 2021:

- A total of 177 countries and economies have started vaccination. In just one month, COVAX has distributed more than 32 million vaccines to 61 countries.
- Four more vaccines are currently at different stages in the process of being assessed for WHO Emergency Use Listing, with the hope to approve at least one of them by the end of April.

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 21 March 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: Release of the WHO COVID-19 Detailed Surveillance Dashboard](#)
- [Special focus: SARS-CoV-2 variants of concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Globally, COVID-19 confirmed cases continued to rise for a fourth consecutive week, with just under 3.3 million new cases reported in the last week (Figure 1). At the same time, the number of new deaths reported plateaued after a six week decrease, with just over 60 000 new deaths reported. Marked increases in the number of new cases were reported from the South-East Asia, Western Pacific, European and Eastern Mediterranean regions, all of which have been on an upward trajectory in recent weeks. Case incidence in the African Region and the Region of the Americas has remained stable in recent weeks, notwithstanding concerning trends observed in some countries within these regions. The European Region and the Region of the Americas continue to account for nearly 80% of all the cases and deaths. The only WHO region to report a decline in new deaths this week was the Western Pacific where deaths fell by nearly a third, compared to the previous week.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 21 March 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from Brazil (508 010 new cases; 3% increase), the United States of America (374 369 new cases; 19% decrease), India (240 082 new cases; 62% increase), France (204 840 new cases; 27% increase), and Italy (154 493 new cases; similar to previous week).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 21 March 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 173 561 (36%)	-5%	53 937 714 (44%)	31 040 (51%)	2%	1 299 243 (48%)

Special Focus: Release of the WHO COVID-19 Detailed Surveillance Dashboard

Over one year into the pandemic, WHO continues to conduct [global surveillance of COVID-19](#) as part of activities on [preparedness, readiness and response activities](#). The need for global surveillance of COVID-19 is greater than ever, as the implementation of vaccination campaigns and the appearance of variants are prone to impact the course of the epidemic, as transmission patterns evolve. Timely and complete surveillance data are key to monitoring these changes.

In addition to the daily count of confirmed cases and deaths of COVID-19, WHO requested all Member States to report a minimal set of information using a [case report form](#) or via the [weekly aggregated surveillance system](#) as specified in the [Public Health Surveillance for COVID-19 interim guidance](#). Member States report primarily via one of the systems; some have switched from case report forms to weekly reporting.

The data reported are now publicly available through the [WHO COVID-19 detailed surveillance data dashboard](#) (Figure 3), without editing or filtering by WHO. Features include stratification by age and sex, trends over time, case fatality ratios by age, testing, hospitalization, and data on health workers – all visible at country and regional levels. The dashboard provides the ability for users to conduct further analyses by country and selected time period.

Figure 3: Snapshot of the COVID-19 Surveillance dashboard

As of 14 March 2021, a total of 186 countries, territories and areas had shared detailed data, via case report forms or weekly aggregate surveillance with WHO. Of the 119 million cases reported globally at this time, WHO has received information for 86.4 million cases (73%). Sex was reported for over 59 million cases (50%), age reported for 45 million cases (38%), and age and sex combined was reported for 42 million cases (36%). There are also data on COVID-19 cases among health workers, with just over 1.6 million cases, and 25 000 deaths, recorded in the system.

Special Focus: Update on SARS-CoV-2 Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available. Further information on the background of the variants of interest (VOIs) and variants of concern (VOCs) is available from previously published editions of the [Weekly Epidemiological Update](#). Here we provide an update on the geographical distribution, and emerging evidence surrounding transmissibility and severity, and potential impacts on vaccines and diagnostics. We also update on emerging VOIs, and a recent workshop on enhancing sequencing for SARS-CoV-2.

Table 2: Overview of emerging information on key variants of concern, as of 23 March 2021*

Nextstrain clade	20I/501Y.V1	20H/501Y.V2 [†]	20J/501Y.V3
PANGO lineage	B.1.1.7	B.1.351	B.1.1.28.1, alias P.1 [†]
GISAID clade	GR	GH	GR
Alternate names	VOC 202012/01 [†]	VOC 202012/02	-
First detected by	United Kingdom	South Africa	Brazil / Japan
First appearance	20 September 2020	Early August 2020	December 2020
Key spike mutations	H69/V70 deletion; Y144 deletion; N501Y; A570D; and P681H	L242/A243/L244 deletion; K417N E484K, N501Y	K417T, E484K; N501Y
Key mutation in common	S106/G107/F108 deletion in Non-Structural Protein 6 (NSP6)		
Transmissibility*	Increased ^{1, 2} (36%-75%) ³ , increased secondary attack rate ⁴ (10% to 13%)	Increased [1.50 (95% CI: 1.20-2.13) times more transmissible than previously circulating variant ^{5, 6}	Increased, more transmissible than previous circulating variants ⁷
Severity*	Possible increased risk of hospitalization ⁸ , severity and mortality ⁴	Possible increased risk of in-hospital mortality by 20% ^{6, 9}	Under investigation, limited impact ⁷
Neutralization capacity*	Slight reduction but overall neutralizing titers still remained above the levels expected to confer protection ¹⁰	Decreased, suggesting potential increased risk of reinfection ^{5, 11, 12}	Decreased, reinfections reported ^{13, 14}
Potential impacts on vaccines*	<ul style="list-style-type: none"> No significant impact on post-vaccine neutralization by Moderna, Pfizer-BioNTech, Oxford-AstraZeneca, Novavax and Bharat vaccines 15-18 No significant change in prevention of disease by Oxford-AstraZeneca, Novavax, and Pfizer¹⁵⁻¹⁷ Evidence for prevention of infection evidence limited. Reduced effect reported for Oxford-AstraZeneca.^{15, 18} 	<ul style="list-style-type: none"> Post-vaccine neutralization reductions range from minimal to moderate for Moderna and Pfizer, however there is also some evidence of more substantial reductions.¹⁹ A single study has evaluated Sinopharm.²⁰ Substantial reductions have been found for the Oxford-AstraZeneca product.^{21, 22} Results for Novavax and Janssen are pending. Efficacy against disease was retained, but somewhat lower, in South Africa when 501Y.V2 was dominant compared to settings without this variant.^{23, 24} In a small study, AstraZeneca did not demonstrate vaccine efficacy against mild-moderate COVID-19 disease, with wide confidence intervals, while efficacy against severe disease was not assessed and is undetermined.^{25, 26} There is no evidence to inform vaccine impact on asymptomatic infection by 501Y.V2. 	<ul style="list-style-type: none"> Limited to modest reduction in post-vaccine neutralization by Oxford-AstraZeneca, Moderna and Pfizer vaccines.^{19, 21, 27-31} Preliminary suggestion of loss of neutralization following vaccination with Sinovac³²
Potential impacts on diagnostics*	S gene target failure (SGTF). ²⁵ No impact on Ag RDTs observed ²³	None reported to date	None reported to date
Countries reporting cases (newly reported in last week)**	125 (7)	75 (11)	41(3)

[†]While work is ongoing to establish standardized nomenclature for key variants, these are the names by which WHO will refer to them in this publication.

*Generalized findings as compared to non-VOC viruses. Based on emerging evidence from multiple countries, including nonpeer-reviewed preprint articles and reports from public health authorities and researchers – all subject to ongoing investigation and continuous revision.

**Includes official and unofficial reports of VOCs detections in countries among either travellers (imported cases only) or community samples (local transmission).

The number of countries reporting VOCs has continued to increase (Table 2, Figures 5, 6 and 7, Annex 2). This information should be interpreted with due consideration of limitations of ongoing surveillance, including but not limited to differences between countries in sequencing capacity and which samples are prioritized for sequencing. WHO continues to advocate for strengthening surveillance and sequencing capacity, and a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants; based on the local epidemiological situation and capacity, and the detection of unusual events.

VOC 202012/01, 501Y.V2 and P.1 have commonly demonstrated an increase in transmissibility compared to wild-type (non-VOC) variants, and a veracity to rapidly replace other circulating strains. We analysed sequence data submitted to GISAID to determine the change in proportion of VOCs over time and calculate the associated change in transmissibility. Variants 202012/01, 501Y.V2 and P.1 rapidly replaced the wild-type variant in the United Kingdom, South Africa and Brazil, respectively (Figure 4). Using a logistic model of competitive growth, the additive increase in the effective reproduction number (R_t) relative to the wild-type variant was estimated at 41% (95% CI: 41–42%) for 202012/01, 36% (95% CI: 32–40%) for 501Y.V2, and 11% (95% CI: 7–16%) for P.1. The transmissibility of P.1 was higher when estimated only for the Amazonas region of Brazil (data not shown), suggesting more rapid replacement of the wild-type variant at a local level. However, the number of sequences was too low to meaningfully quantify the change in R_t . These analyses assume that sequence data submitted to GISAID is representative of the variants circulating in the region under consideration; if sequencing efforts are targeted at suspected VOCs, the rate of replacement and associated increased transmissibility of VOCs may be overestimated.

Figure 4. Proportion of SARS-CoV-2 202012/01, 501Y.V2 and P.1 variants over time in the United Kingdom, South Africa and Brazil, respectively. The estimated increase in R_t and associated 95% confidence interval is indicated below the country name.

Variant VOC 20212/01

Since our last update on 16 March, VOC 20212/01 has been detected in seven additional countries. As of 23 March, a total of 125 countries across all six WHO regions have reported cases of this variant (Figure 5).

Previous studies have shown VOC 20212/01 may be associated with an increased risk of hospitalization, severity and mortality.^{4, 8} A recently published matched cohort study provides additional evidence, highlighting that there is a higher risk of mortality when infected by VOC 20212/01. The study involved nearly 55 000 matched pairs of participants who tested positive for SARS-CoV-2 between 1 October 2020 and 29 January 2021 and were followed-up until 12 February 2021. Results showed an increased mortality hazard ratio of 1.64 (95% confidence interval 1.32 to 2.04). This ratio was associated with infection with VOC 20212/01 compared with infection with previously circulating variants, in patients who tested positive for COVID-19 in the community. Although this constitutes a comparatively low risk group overall, it represents an increase in deaths from 2.5 to 4.1 per 1000 detected cases.

Vaccine updates

There is a growing body of evidence on vaccine-induced neutralizing antibody activity against VOC20212/01, including for AstraZeneca, Moderna, Pfizer, Novavax, and Bharat vaccines. The findings support that neutralizing activity is largely sustained against this variant.^{10, 33} Additional evidence is available on the ability of vaccines to protect against disease from VOC 20212/01 are available for the AstraZeneca and Pfizer vaccines, from a randomized controlled trial (RCT) in the UK (AstraZeneca) and observational evidence (Pfizer and AstraZeneca) from the UK during the period when VOC 20212/01 was prevalent.¹⁷ Results from a test-negative case control study conducted in England from December 2020 to February 2021 when VOC20212/01 was very prevalent, showed the early real-world effectiveness of the Pfizer/BioNTech - BNT162b2 vaccine and AstraZeneca - ChAdOx1 vaccine against confirmed COVID-19, hospitalizations and deaths.¹⁷ This study also estimated effectiveness on the VOC20212/01. Both vaccines show that vaccination with either a single dose of BNT162b2 or ChAdOx1 was associated with a significant reduction in symptomatic COVID-19 cases in older adults (>70 years old) with even greater protection against severe disease.

Evidence for vaccines to protect against asymptomatic infection, which would influence community transmission, is limited to the RCT in the UK of the AstraZeneca product.¹⁵ Although effectiveness against disease was largely sustained against VOC20212/01, preliminary evidence suggests that the efficacy against asymptomatic infection is reduced in the face of this variant.

Figure 5. Countries, territories and areas reporting SARS-CoV-2 VOC 20212/01 as of 23 March 2021

Variant 501Y.V2

Since the last update on 16 March, 501Y.V2 has been reported from 11 additional countries – totaling 75 countries across all six WHO regions (Figure 6). In several areas within the African Region, variant 501Y.V2 has been reported to comprise a high proportion of sequenced samples, including over 90% of sequenced specimens in some settings.^{34, 35}

A newly released population-based study in South Africa, available in preprint, compared in-hospital mortality during its first wave peaking in mid-July 2020 to the second wave peaking in January 2021 when variant 501Y.V2 was the predominant variant. After adjusting for weekly hospital admissions, the risk of in-hospital mortality increased by 20% (adjusted odds ratio of 1.2, 95%CI 1.2-1.3).⁹

Vaccine updates

Reductions in neutralizing antibody activity against 501Y.V2 induced by vaccines or natural infection compared with wild-type (non-VOC) variants, have been documented in a substantial number of studies.^{5, 30} Findings from a recent study that analyzed convalescent plasma from 20 patients and sera from 22 participants of vaccine trials [Moderna SARS-CoV-2 mRNA-1273 vaccine (12 participants); Pfizer BNT162b2 COVID-19 vaccine (10 participants)] indicated that relative to wild-type variants, there was a substantial decrease in the neutralizing activity of convalescent plasma (9.4-fold) and sera from vaccinated participants (10.3 to 12.4-fold) against 501Y.V2.³¹ In addition, T-cell analyses suggest this component of the vaccine induced immune response is less influenced by the variants than the impact on the neutralization activity.³⁶

Evidence of vaccine efficacy against clinical disease from B.1.351 is available for AstraZeneca, Janssen and the Novavax vaccines.^{24, 37, 38} Comparisons are hampered by different case definitions, and trials sizes. Although there appears to be some reduction in efficacy compared with non-B.1.351 strains, both the Novavax and the Janssen product retain significant efficacy. The AstraZeneca trial found no statistically significant efficacy; however, this trial was of a small sample size, had only mild and moderate cases and used a dosing interval of 4 weeks.³⁷ Separate evidence indicates a longer dosing interval improves both immunogenicity and efficacy, which along with other evidence leave open the plausibility that efficacy against severe disease may be partially retained.

Figure 6. Countries, territories and areas reporting SARS-CoV-2 501Y.V2 as of 23 March 2021

Variant P.1

Since our last update, variant P.1 has been reported in three additional countries. As of 23 March, this variant is reported in 41 countries across all six WHO regions (Figure 7).

A recent study analyzed the national health surveillance data of hospitalizations and frequency of variant P.1 in Manaus city, in Amazonas State, Brazil where this variant was first detected and has widely spread. Based on the preliminary findings, P.1 is found to be 2.5 times more transmissible (95% CI:2.3–2.8) compared to the previously circulating variant while the reinfection probability was found to be low i.e. 6.4% (CI:5.7–7.1%).³⁹ Two additional studies analyzed the genomic data from Manaus and estimated higher transmissibility of the P.1 variant.^{7, 14} However, these are preliminary findings and more studies are required to fully understand the transmissibility and severity of P.1 variant.

Vaccine updates

Numerous studies have measured the neutralization of variant P.1 by sera from those vaccinated with Pfizer, Moderna, AstraZeneca or Sinovac against SARS-CoV-2 virus including in Manaus.^{21, 27–32 19} Based on these findings, the neutralization activity was reduced by 2.6 to 10-fold depending on the vaccine and individuals. In particular, among people vaccinated with the Sinovac product (CoronaVac vaccine), the plasma failed to efficiently neutralize variant P.1 suggesting possibility of reinfection. One T-cell study concluded that response was largely preserved.³⁶ There are no clinical outcome data following vaccination which are needed to understand the implications of the limited to moderate loss of neutralization activity.

Figure 7. Countries, territories and areas reporting SARS-CoV-2 P.1 variant as of 23 March 2021

WHO Global workshop on enhancing sequencing for SARS-CoV-2, 19 March 2021

On 19 March 2021, WHO hosted a global workshop on enhancing sequencing to monitor SARS-CoV-2 evolution, bringing together stakeholders in a high level discussion to agree on a common vision and a global, coordinated plan to increase SARS-CoV-2 sequencing capacity, in order to strengthen detection of VOIs and VOCs. Over 800 participants joined this virtual workshop, including representatives from Ministries of Health,

academia and donors, engaging in discussions on the international sequencing landscape, available capacities and opportunities for network-driven strengthening of SARS-CoV-2 variant detection.

The workshop highlighted how we can leverage existing surveillance systems and structures, such as existing SARS-CoV-2 reference network, the Global Influenza Surveillance and Response System (GISRS), HIV, TB and Polio laboratory networks, to strengthen existing regional networks, and to build new sustainable capacity to generate and process sequencing data for SARS-CoV-2 and other infectious pathogens. Sequence and supporting meta-data sharing is critical to better understand virus evolution and to inform the COVID-19 response. The workshop outcomes were as follows:

- A situational overview of national and regional sequencing and data analysis capacities around the world and demonstration of ongoing support from Member States with capacities to support others.
- An agreement from participants on the importance of timely data sharing and a need to build capacity for sequencing, data processing leading to informed action.
- An agreement toward a global plan to enhance sequencing and analysis capacities and linking results with public health actions.

The workshop outlined the need for global coordination of sequencing capacity. WHO will provide the coordination role by providing a platform, leadership and coordination for future discussions, capacity building and network-based knowledge sharing. The workshop will inform discussions at the upcoming Global Consultation on a Decision Framework for Assessing the Impact of SARS-CoV-2 Variants of Concern on Public Health Interventions on 29 March 2021.

Emerging variants of interest (VOIs)

All viruses, including SARS-CoV-2, change over time resulting in the emergence of new variants, most without a direct benefit to the virus or other public health impacts. WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they impact on public health and social measures (PHSM). Systems have been established to detect “signals” of potential variants of interest or concern, as well as unusual events potentially associated with a variant, and assess these based on the risk posed to global public health (see also [working definitions](#)). A number of such signals are currently under assessment, and as new VOIs or VOCs are determined, WHO is committed to highlighting these to support prioritization for further monitoring and assessment. Table 3 summarises assessed and designated VOIs as of 23 March 2021. National authorities may choose to designate other variants of local interest/concern as every local situation is unique, with different variants circulating, requiring surveillance and response systems to adapt to their local epidemiological situation.

Table 3: Overview of variants of interest (VOIs), as of 23 March 2021*

WHO recommendations

The potential for virus mutation increases with the frequency of human and animal infections. Therefore, reducing transmission of SARS-CoV-2 by using established disease control methods as well as avoiding introductions to animal populations, are critical aspects to the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM remain critically important to curb the spread of SARS-CoV-2, including newly reported variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of physical distancing and other PHSM as well as infection prevention and control (IPC) measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. Findings from new studies evaluating transmission, severity and impact on medical countermeasures will continue to help inform PHSM and IPC measures employed by Member States. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities, including epidemiological surveillance, strategic testing, and systematic sequencing of SARS-CoV-2 where feasible.

WHO regional overviews

African Region

The African Region reported nearly 51 000 new cases and over 1400 new deaths, a 3% decrease and a 10% increase respectively compared to the previous week. This is the first time in eight weeks, that an increase in new deaths has been reported. The highest numbers of new cases were reported from Ethiopia (11 587 new cases; 10.1 new cases per 100 000 population; a 28% increase), South Africa (8387 new cases; 14.1 new cases per 100 000; a 2% increase), and Kenya (7358 new cases; 13.7 new cases per 100 000; a 66% increase).

The highest numbers of new deaths were reported in the same countries, from South Africa (821 new deaths; 1.4 new deaths per 100 000 population; a 34% increase), Ethiopia (107 new deaths; 0.1 new deaths per 100 000; a 11% decrease), and Kenya (79 new deaths; 0.1 new deaths per 100 000; a 132% increase).

Region of the Americas

The Region of the Americas reported nearly 1.2 million new cases and just over 31 000 new deaths, a 5% decrease and a 2% increase respectively compared to the previous week. After six weeks of decline in deaths, this week there has been a slight increase reported. The highest numbers of new cases were reported from Brazil (508 010 new cases; 239 new cases per 100 000; a 3% increase), the United States of America (374 369 new cases; 113.1 new cases per 100 000; an 19% decrease), and Peru (49 035 new cases; 148.7 new cases per 100 000; a 11% increase).

The highest numbers of new deaths were reported from Brazil (15 209 new deaths; 7.2 new deaths per 100 000; a 23% increase), the United States of America (7552 new deaths; 2.3 new deaths per 100 000; a 19% decrease), and Mexico (3368 new deaths; 2.6 new deaths per 100 000; a 21% decrease).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported nearly 264 000 new cases and just over 3200 new deaths, an 8% and a 12% increase respectively compared to the previous week. New weekly cases have increased for the past six weeks and deaths have increased for the past four weeks. The highest numbers of new cases were reported from Jordan (57 666 new cases; 565.2 new cases per 100 000; a 21% increase), the Islamic Republic of Iran (54 445 new cases; 64.8 new cases per 100 000; a 6% decrease), and Iraq (35 072 new cases; 87.2 new cases per 100 000; a 13% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (582 new deaths; 0.7 new deaths per 100 000; a 6% increase), Jordan (503 new deaths; 4.9 new deaths per 100 000; a 31% increase), and Lebanon (381 new deaths; 5.6 new deaths per 100 000; an 19% increase).

European Region

The European Region reported over 1.4 million new cases and nearly 22 000 new deaths, a 13% and a 1% increase respectively compared to the previous week. Cases in the Region have been steadily increasing over the past four weeks. The highest numbers of new cases were reported from France (204 840 new cases; 313.8 new cases per 100 000; a 27% increase), Italy (154 493 new cases; 255.5 new cases per 100 000; similar to the previous week), and Poland (151 918 new cases; 401.4 new cases per 100 000; a 36% increase).

The highest numbers of new deaths were reported from Russian Federation (2940 new deaths; 2 new deaths per 100 000; a 2% decrease), Italy (2761 new deaths; 4.6 new deaths per 100 000; a 20% increase), and Poland (2122 new deaths; 5.6 new deaths per 100 000; a 12% increase).

South-East Asia Region

The South-East Asia Region reported over 298 000 new cases and over 2400 new deaths, a 49% and a 14% increase respectively compared to the previous week. Eighty per cent of all new cases were reported from India. The highest numbers of new cases were reported from India (240 082 new cases; 17.4 new cases per 100 000; a 62% increase), Indonesia (41 047 new cases; 15.0 new cases per 100 000; similar to the previous week), and Bangladesh (12 470 new cases; 7.6 new cases per 100 000; a 91% increase).

The same countries reported the highest numbers of new deaths in the region; India (1148 new deaths; 0.1 new deaths per 100 000; a 35% increase), Indonesia (1118 new deaths; 0.4 new deaths per 100 000; a 5% decrease), and Bangladesh (141 new deaths; 0.1 new deaths per 100 000; an 86% increase).

Western Pacific Region

The Western Pacific Region reported nearly 64 000 new cases and nearly 500 new deaths, a 29% increase and a 33% decrease respectively compared to the previous week. Although the number of new cases in the region has increased for the third consecutive week, the number of new weekly deaths continues to decline. The highest numbers of new cases were reported from the Philippines (39 445 new cases; 36 new cases per 100 000; a 55% increase), Malaysia (9304 new cases; 28.7 new cases per 100 000; a 12% decrease), and Japan (8765 new cases; 6.9 new cases per 100 000; a 11% increase).

The highest numbers of new deaths were reported from Japan (252 new deaths; 0.2 new deaths per 100 000; a 24% decrease), the Philippines (164 new deaths; 0.1 new deaths per 100 000; a 45% decrease), and the Republic of Korea (27 new deaths; 0.1 new deaths per 100 000; a 23% decrease). Japan and the Philippines reported 86% of new weekly deaths in the Region.

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 14 March 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: Building and maintaining trust - what countries should do to prepare communities for a COVID-19 vaccine, treatment, or a new test](#)
- [Special focus: SARS-CoV-2 variants of concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

New cases continue to rise globally, increasing by 10% in the past week to over 3 million new reported cases (Table 1). The number of new cases peaked in [early January](#) 2021 when there were just under 5 million cases reported in one week. New cases then declined to just under 2.5 million cases by the [week commencing 15 February](#). However, for the past three weeks new cases have increased. This week, the Americas and Europe continue to account for over 80% of new cases and new deaths, with rises in new cases seen in all regions apart from Africa, where incidence rates remained similar to the previous week. New deaths on the other hand continue to decline and are now under 60 000, since peaking in the week commencing [18 January](#) (when there were over 95 000 new deaths in the week). The last time when there were fewer than 60 000 new weekly deaths was four months ago, in the week commencing [9 November](#). This week, although new deaths declined globally, they rose in two WHO regions; the Eastern Mediterranean (by 7%) and the Western Pacific (by 14%).

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 14 March 2021**

** See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from Brazil (494 153 new cases; 20% increase), the United States of America (461 190 new cases; 8% increase), France (161 159 new cases; 12% increase), Italy (155 076 new cases; 12% increase), and India (148 249 new cases; 30% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 14 March 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 241 439 (41%)	13%	52 763 406 (44%)	30 596 (52%)	-6%	1 268 186 (48%)
Europe	1 236 697 (41%)	6%	41 043 949 (34%)	20 977 (36%)	-1%	906 843 (34%)
South-East Asia	199 924 (7%)	19%	13 884 294 (12%)	2 141 (4%)	-3%	212 355 (8%)
Eastern Mediterranean	251 375 (8%)	14%	6 860 070 (6%)	2 955 (5%)	7%	150 173 (6%)
Africa	54 225 (2%)	0%	2 948 236 (2%)	1 309 (2%)	-6%	74 685 (3%)
Western Pacific	49 553 (2%)	19%	1 711 830 (1%)	720 (1%)	14%	30 357 (1%)
Global	3 033 213 (100%)	10%	119 212 530 (100%)	58 698 (100%)	-3%	2 642 612 (100%)

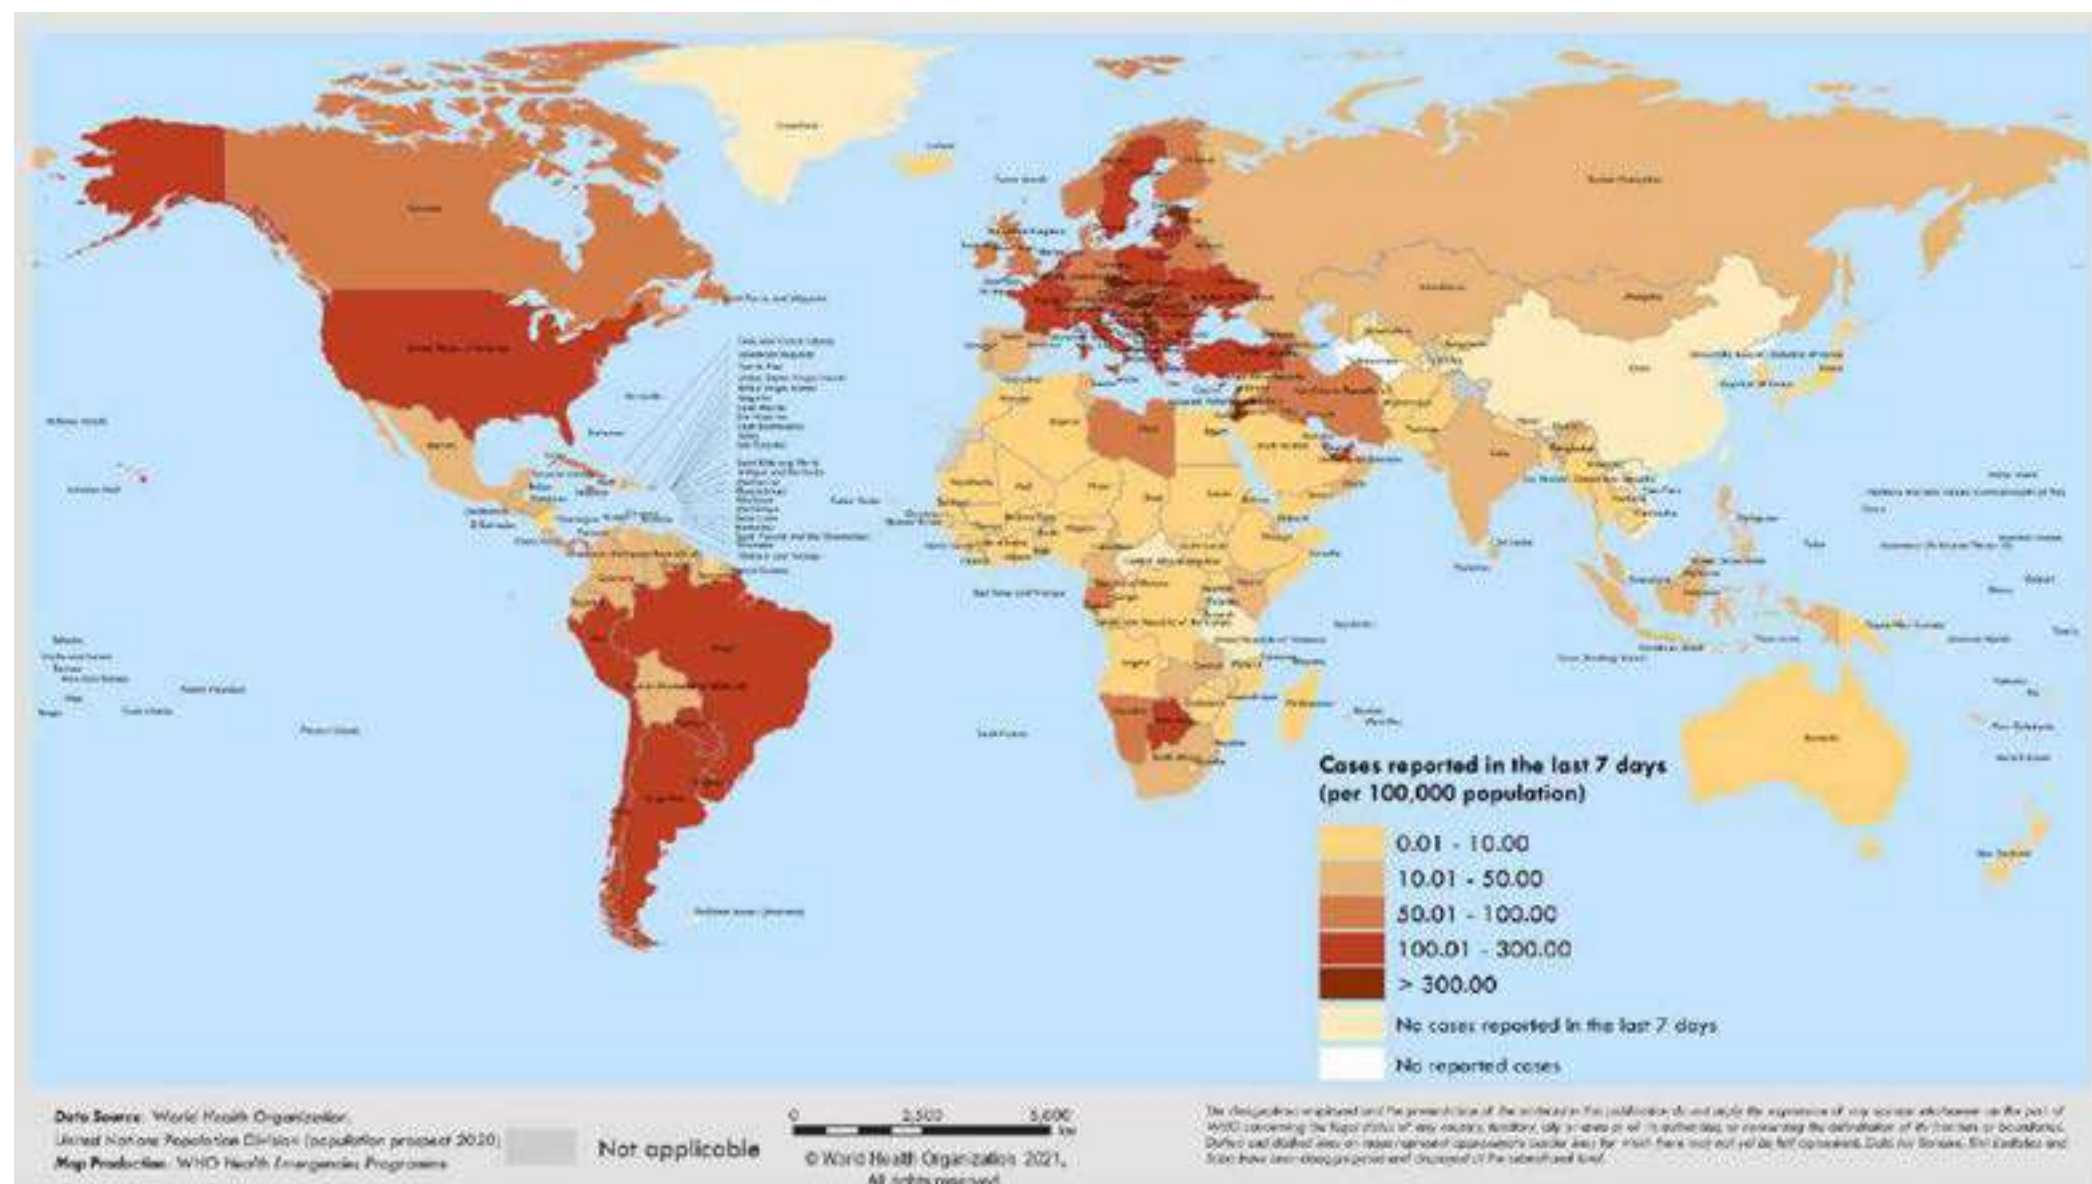

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior. Regional percentages rounded to the nearest whole number; global totals may not equal 100%.

Special Focus: Building and maintaining trust - what countries should do to prepare communities for a COVID-19 vaccine, treatment, or a new test

As we move to the next critical phase of the response, when vaccines and other biomedical tools become more widely available, building trust and engaging communities remains essential. We have learned from previous epidemic responses that when communities fully engage and actively participate in the full cycle of planning, delivery and assessment for new biomedical tools, demand for these tools increases, leading to widespread and effective uptake and use.

Addressing community concerns

Social-behavioral data tell us that we have much to do in order to build and sustain trust in communities around the world.

People have concerns over the safety of vaccines and other biomedical tools made with unprecedented speed and with new technologies. These concerns must be acknowledged and addressed by providing individuals and communities with actionable, timely and credible health information from trusted sources and by providing the space and follow-up necessary to work through these concerns with trusted health or community leaders. Past epidemics have shown us just how quickly and widely individual or community fears can spread if not dealt with in a timely and comprehensive way.

Recent studies suggest that around 65% of global populations surveyed are willing to be vaccinated with a COVID-19 vaccine.¹ But this has fluctuated over time. The proportion of those likely to accept a COVID-19 vaccine varies significantly between regions and countries and within countries. The barriers to vaccine uptake are likely to be influenced by a large range of factors.² These include exposure to misinformation and rumours, which can negatively impact on vaccine confidence, as well as the role local health care professionals play in promoting vaccine uptake among their patients and communities.³

As the pandemic becomes protracted, pandemic fatigue is increasing. The growing fatigue, the stress caused by uncertainty, lower risk perceptions, and reduced trust in government responses, are taking a toll on the fabric of our communities. This has already led to stigma and discrimination in some settings as well as protests against public health and social measures in many countries.

This is why since the beginning of the pandemic, WHO has promoted and provided guidance on implementing a whole-of-society approach to ensure the widest array of stakeholders are actively involved in the introduction of new biomedical tools, while also supporting communities' broader trust in their health systems.

One of the ways WHO is supporting countries strengthen their engagement and empowerment strategies is through the publication of the [10 Steps to Community Readiness – What countries should do to prepare communities for a COVID-19 vaccine, treatment, or new test](#).

This is a new tool, developed by WHO, UNICEF, IFRC and the Global Outbreak and Alert Response Network (GOARN) through the Risk Communication and Community Engagement (RCCE) Collective Service (a new partnership launched in June 2020), to strengthen coordination and quality of practice for the COVID-19 pandemic response.

¹ Johns Hopkins University, WHO, GOARN, Facebook, MIT (2021) KAP COVID-19 - Vaccine acceptance around the world. <https://ccp.jhu.edu/kap-covid/vaccine-acceptance>

² Anthrologica (2020) Literature analysis: norms and practices relevant to COVID-19 in the Middle East and North Africa Region.

³ PERC (2020) Responding to COVID-19 in Africa: using data to find a balance Part II. <https://preventepidemics.org/covid19/perc/>

Figure 3: 10 Steps to Community Readiness

The tool is built around the recognition that the empowerment of people and communities is not an abstract idea, and there are concrete and measurable steps that can be taken to ensure citizens are engaged and ready to support new biomedical tools.

Though communication needs may be slightly different for each step, the principles that promote their safe and successful introduction remain the same.

The steps build on well-established RCCE principles that put communities at the heart of the roll-out of new vaccines, treatments, and tests, and promote trust – the critical ingredient for all community action.

With the imminent arrival of new biomedical tools, investments in coordinated and proactive community engagement approaches, such as the 10 Steps to Community Readiness, are now needed more than ever. These approaches not only support the widest possible uptake of new tools but also support the continued maintenance of protective behaviours, such as mask wearing and physical distancing.

Special Focus: Update on SARS-CoV-2 Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants. Further information on the background of the variants of concern (VOCs) is available in previously published editions of the [Weekly Epidemiological Update](#). Here we provide an update on the geographical distribution of the three VOCs, considered as such by WHO and as reported by countries, territories and areas (hereafter countries) as of 16 March 2021; and emerging variants of interest (VOIs).

As surveillance activities, including systematic genomic sequencing, are strengthened at local and national levels to detect cases infected with SARS-CoV-2 variants, the number of countries reporting VOCs has continued to increase (Table 2, Figures 4-6, Annex 2). This information should be interpreted with due consideration of limitations of ongoing surveillance, including but not limited to differences between countries in sequencing capacity and which samples are prioritized for sequencing. WHO continues to advocate for strengthening surveillance and sequencing capacity, and a systematic approach to provide a representative indication of the extent of transmission of SARS-CoV-2 variants; based on the local epidemiological situation and capacity, and the detection of unusual events.

Table 2: Overview of emerging information on key variants of concern, as of 16 March 2021*

Nextstrain clade	20I/501Y.V1	20H/501Y.V2 [†]	20J/501Y.V3
PANGO lineage	B.1.1.7	B.1.351	B.1.1.28.1, alias P.1 [†]
GISAID clade	GR	GH	GR
Alternate names	VOC 202012/01 [†]	VOC 202012/02	-
First detected by	United Kingdom	South Africa	Brazil / Japan
Earliest sample date	20 September 2020	Early August 2020	December 2020
Key spike mutations	H69/V70 deletion; Y144 deletion; N501Y; A570D; P681H	L242/A243/L244 deletion; K417N; E484K; N501Y	K417T, E484K; N501Y
Key mutation in common	S106/G107/F108 deletion in Non-Structural Protein 6 (NSP6)		
Countries reporting cases (newly reported in last week)**	118 (7)	64 (6)	38 (6)

[†]While work is ongoing to establish standardized nomenclature for key variants, these are the names by which WHO will refer to them in this publication. ^{**}Includes official and unofficial reports of VOCs detections in countries among either travellers (imported cases only) or community samples (local transmission).

Figure 4. Countries, territories and areas reporting SARS-CoV-2 VOC 202012/01 as of 16 March 2021

Figure 5. Countries, territories and areas reporting SARS-CoV-2 variant 501Y.V2 as of 16 March 2021

Figure 6. Countries, territories and areas reporting SARS-CoV-2 variant P.1 as of 16 March 2021

Emerging variants of interest (VOIs)

All viruses, including SARS-CoV-2, change over time resulting in the emergence of new variants, most without a direct benefit to the virus or other public health impacts. WHO, in collaboration with national authorities, institutions and researchers, routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they impact on public health and social measures (PHSM). Systems have been established to detect “signals” of potential variants of interest or concern, as well as unusual events potentially associated with a variant, and assess these based on the risk posed to global public health (see also [working definitions](#)). Such signals are currently under assessment, and as new variants of interest VOIs or VOCs are determined, WHO is committed to highlighting these to support prioritization for further monitoring and assessment.

A SARS-CoV-2 variant, labelled CAL.20C/L452R (based upon the NextStrain subclade and key mutation), spanning PANGO lineages B.1.427 and B.1.429, has been designated as a VOI by WHO based on recent assessments and emerging evidence. This variant is characterized by a combination of three mutations in the receptor binding domain (RBD), namely S13I, W152C, L452R, of which the focus is on the L452R mutation. It was first detected during a local increase in COVID-19 cases in California, United States of America in June 2020. Surveillance has shown that it has since contributed to a substantive proportion of local COVID-19 cases in California, and has been detected in all US states and at least 26 other countries to date¹⁻⁴. Outside of the US, reported detections of this VOI are currently limited to a relatively low number of sequences, suggesting it has not yet resulted in widespread disease in other countries.

The assessment as a VOI follows preliminary, emerging evidence that this variant may be associated with phenotypic impacts which may pose an increased public health risk and COVID-19 control measures compared to other variants. This includes a possible increase in transmissibility,¹ mixed findings on potentially higher infectivity (based on PCR cycle thresholds as a proxy),^{1,5,6} and a slight reduction in neutralization for sera from recovered patients clinically diagnosed with COVID-19 and in vaccine recipients.^{1,7} The L452R mutation has been associated with a reduction in neutralization of monoclonal antibodies but further investigations are ongoing^{8,9}. The impact of this variant on disease severity is under investigation. These are preliminary findings, include non-peer review studies, and require further investigations. WHO is working with US Centers for Disease Control and Prevention (CDC) and the WHO Virus Evolution Working Group to further assess this VOI.

WHO recommendations and working definitions of VOI and VOC

The potential for virus mutation increases with the frequency of human and animal infections. Therefore, reducing transmission of all circulating SARS-CoV-2 viruses and variants by using established disease control methods, are critical aspects of the global strategy to reduce the occurrence of mutations that have negative public health implications. PHSM and infection prevention and control measures inside and outside of health facilities remain critically important to curb the spread of SARS-CoV-2, including newly reported variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of physical distancing and other PHSM, as well as infection prevention and control (IPC) measures in health facilities, has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. Findings from new studies evaluating transmission, severity and impact on medical countermeasures will continue to help inform PHSM and IPC measures employed by Member States. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities, including epidemiological surveillance, strategic testing, and systematic sequencing of SARS-CoV-2 where feasible.

On 25 February 2021, [proposed working definitions of SARS-CoV-2 Variants of Interest and Variants of Concern](#) were published. As SARS-CoV-2 is continuously evolving, and new signals of potential VOIs and VOCs are frequently detected, WHO aims to assess potential VOCs based on the risk posed to global public health. National authorities may choose to designate other variants of local interest/concern as every local situation is unique, with different variants circulating, requiring surveillance and response systems to adapt to their local epidemiological situation.

If potential VOIs or VOCs are detected, Member States are requested to inform WHO through established WHO Country or Regional Office reporting channels, submit genome sequences to publicly available databases (e.g., GISAID), and perform field and laboratory investigations (where appropriate) to improve understanding of potential impacts.

WHO regional overviews

African Region

The African Region reported over 54 000 new cases, a number similar to last week, while deaths decreased by 6% compared to the previous week with just over 1300 deaths reported. The decreasing trend in deaths has been observed since early February 2021. The highest numbers of new cases were reported from Ethiopia (9025 new cases; 7.9 new cases per 100 000 population; a 29% increase), South Africa (8208 new cases; 13.8 new cases per 100 000; a 3% increase), and Kenya (5476 new cases; 10.2 new cases per 100 000; a 226% increase).

The highest numbers of new deaths were reported from South Africa (614 new deaths; 1.0 new deaths per 100 000 population; a 13% decrease), Ethiopia (120 new deaths; 0.1 new deaths per 100 000; an 82% increase), and Botswana (65 new deaths; 2.8 new deaths per 100 000; a 33% increase).

Region of the Americas

The Region of the Americas reported over 1.2 million new cases and over 30 000 new deaths, a 13% increase and a 6% decrease respectively compared to the previous week. Deaths continued to decrease for the second consecutive week. The highest numbers of new cases were reported from Brazil (494 153 new cases; 232.5 new cases per 100 000; a 20% increase), the United States of America (461 190 new cases; 139.3 new cases per 100 000; an 8% increase), and Peru (52 763 new cases; 160.0 new cases per 100 000; a 58% increase).

The highest numbers of new deaths were reported from Brazil (12 335 new deaths; 5.8 new deaths per 100 000; a 24% increase), the United States of America (9381 new deaths; 2.8 new deaths per 100 000; a 24% decrease), and Mexico (4273 new deaths; 3.3 new deaths per 100 000; a 16% decrease). These three countries accounted for 85% of deaths reported in the Americas this week.

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 251 000 new cases and just under 3000 new deaths, a 14% and a 7% increase respectively compared to the previous week. New weekly cases have increased for the past five weeks and deaths have increased for the past three weeks. The highest numbers of new cases were reported from the Islamic Republic of Iran (65 890 new cases; 78.4 new cases per 100 000; a 31% increase), Jordan (47 585 new cases; 466.4 new cases per 100 000; a 36% increase), and Iraq (31 129 new cases; 77.4 new cases per 100 000; a 1% increase).

The highest numbers of new deaths were reported from the Islamic Republic of Iran (630 new deaths; 0.8 new deaths per 100 000; an 18% increase), Jordan (385 new deaths; 3.8 new deaths per 100 000; a 71% increase), and Lebanon (321 new deaths; 4.7 new deaths per 100 000; an 11% decrease).

European Region

The European Region reported over 1.2 million new cases and just under 21 000 new deaths, a 6% increase and a 1% decrease respectively compared to the previous week. Cases in the Region have been steadily increasing over the past three weeks while trends in new deaths have been consistently declining for the past eight weeks. The highest numbers of new cases were reported from France (161 159 new cases; 246.9 new cases per 100 000; a 12% increase), Italy (155 076 new cases; 256.5 new cases per 100 000; a 12% increase), and Poland (111 718 new cases; 295.2 new cases per 100 000; a 27% increase).

The highest numbers of new deaths were reported from the Russian Federation (2990 new deaths; 2.0 new deaths per 100 000; similar to the previous week), Italy (2303 new deaths; 3.8 new deaths per 100 000; an 11% increase), and Poland (1893 new deaths; 5.0 new deaths per 100 000; a 25% increase).

South-East Asia Region

The South-East Asia Region reported just under 200 000 new cases and just over 2100 new deaths, a 19% increase and a 3% decrease respectively compared to the previous week. The highest numbers of new cases were reported from India (148 249 new cases; 10.7 new cases per 100 000; a 30% increase), Indonesia (40 905 new cases; 15.0 new cases per 100 000; a 9% decrease), and Bangladesh (6512 new cases; 4.0 new cases per 100 000; a 67% increase).

The highest numbers of new deaths were reported from Indonesia (1175 new deaths; 0.4 new deaths per 100 000; similar to the previous week), India (851 new deaths; 0.1 new deaths per 100 000; a 21% increase), and Bangladesh (76 new deaths; <0.1 new deaths per 100 000; a 49% increase).

Western Pacific Region

The Western Pacific Region reported just under 50 000 new cases and over 700 new deaths, a 19% and a 14% increase respectively compared to the previous week. This is the first time in seven weeks that an increase in new cases has been reported with new deaths also showing an uptick. The highest numbers of new cases were reported from the Philippines (25 473 new cases; 23.2 new cases per 100 000; a 51% increase), Malaysia (10 632 new cases; 32.8 new cases per 100 000; a 21% decrease), and Japan (7917 new cases; 6.3 new cases per 100 000; a 10% increase).

The highest numbers of new deaths were reported from Japan (333 new deaths; 0.3 new deaths per 100 000; a 9% decrease), the Philippines (301 new deaths; 0.3 new deaths per 100 000; a 71% increase), and Malaysia (40 new deaths; 0.1 new deaths per 100 000; an 11% decrease).

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.

- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 7 March 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: Global Influenza Surveillance and Response System – best practices for integrating influenza and COVID-19 sentinel surveillance](#)
- [Special focus: SARS-CoV-2 sero-epidemiology in Kenya](#)
- [Special focus: SARS-CoV-2 variants of concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Over 2.7 million new cases were reported last week, a 2% increase compared to the previous week (Figure 1). The global case increase was driven by increases in the Eastern Mediterranean (10%), African Region (10%), and Europe (4%), while small declines were seen in the Americas (-2%), South-East Asia (-2%) and Western Pacific regions (-6%). Globally, around half of countries are seeing declines while the other half are experiencing increasing numbers of new cases. Global new deaths continued the downward trend observed since early February 2021, declining a further 6% compared to last week. Death rates declined in all regions except in the Eastern Mediterranean, where new deaths reported rose by 9%. The Americas and Europe account for around 80% of new cases and new deaths reported globally.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 7 March 2021**

**See [Annex: Data, table and figure notes](#)

The highest numbers of new cases were reported from the United States of America (427 233 new cases; 10% decrease), Brazil (413 597 new cases; 11% increase), France (143 622 new cases; 4% decrease), Italy (138 937 new cases; 24% increase), and India (114 068 new cases; 9% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 7 March 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 105 355 (40%)	-2%	51 531 438 (44%)	32 535 (54%)	-4%	1 237 781 (48%)
Europe	1 136 080 (42%)	4%	39 775 409 (34%)	20 770 (34%)	-6%	884 218 (34%)

Special Focus: Global Influenza Surveillance and Response System – best practices for integrating influenza and COVID-19 sentinel surveillance

WHO [estimates](#) that seasonal influenza may result in 290 000 – 650 000 deaths each year due to respiratory diseases alone, with further deaths from other diseases such as cardiovascular disease, which can be influenza-related. SARS-CoV-2 is also a respiratory virus like influenza, but they are not the same virus. In 2020, there were around 1.8 million COVID-19 deaths. Influenza surveillance systems have been leveraged to support monitoring SARS-CoV-2 and have proven to be efficient, practical and sustainable. In this Special Focus, we look at how influenza surveillance systems work, how they are being used to provide effective support to monitor SARS-CoV-2 and other respiratory viruses, and provide some country examples.

How influenza surveillance systems work

[Influenza surveillance](#) uses complementary information from multiple systems to monitor influenza viruses and diseases, assess associated epidemic and pandemic risks including severity, and inform development and update of vaccines and control measures. Influenza is typically monitored using country information coming from:

- Syndromic disease surveillance – monitoring the frequency of a combination of symptoms associated with influenza in people seeking healthcare;
- Virological surveillance – testing all or a subset of ill patients for influenza and other respiratory viruses;
- Other data sources, such as excess mortality and participatory surveillance – monitoring the frequency of syndromes in people who may not seek healthcare for their symptoms; and,
- Event-based surveillance – looking for unusual events.

Influenza surveillance systems have been established in more than 100 countries and are functioning within the Global Influenza Surveillance and Response System (GISRS). For more than half a century, GISRS has been the global platform for surveillance and control of influenza, and other respiratory viruses.

How existing influenza systems are being used to monitor SARS-CoV-2

Influenza and other respiratory viruses, including SARS-CoV-2, are respiratory pathogens which can cause similar symptoms. This makes the use of existing respiratory syndromic surveillance an asset to monitor SARS-CoV-2 circulation, to complement other outbreak surveillance, and to monitor efforts of the COVID-19 pandemic response.

At the same time, using the same systems to monitor influenza and SARS-CoV-2 enables an assessment of the relative co-circulation of both viruses. This allows for concurrent national and global response measures for both influenza and COVID-19. WHO has provided [practical guidance](#) to countries to use existing systems for sentinel surveillance and laboratory testing algorithms for influenza and SARS-CoV-2.

As mentioned in the [Special Focus of 16 February 2021](#), since early 2020, more and more countries have started using the existing influenza surveillance systems to monitor COVID-19, continuing and even enhancing syndromic and virologic surveillance to understand community transmission trends for COVID-19 and influenza. So far, since the onset of the COVID-19 pandemic, influenza has been circulating at very low levels.

Influenza surveillance systems have been fully established in many developing and developed countries. These systems, which proved their value in the 2009 H1N1 pandemic, are ready resources in countries for national integrated surveillance for influenza, SARS-CoV-2 and other existing or future important respiratory viruses to public health. Influenza has been and will continue to be among the top global health threats via seasonal epidemics, zoonotic outbreaks and pandemics. Investing in influenza surveillance systems and pandemic preparedness are key to protecting national and global health security.

Country examples

Many countries have benefited from using their influenza surveillance systems to tackle COVID-19 without compromising their continued ability to protect people from the threat of influenza. Below we highlight some country examples.

- The existing influenza surveillance infrastructure in **Afghanistan**, from the the sentinel sites and staff who are experienced in sample collection to the expertise and resources at the National Influenza Centre, allowed for a rapid response to surveillance for COVID-19 following the detection of the first case in February 2020 in the country. Importantly, the country has continued to monitor trends in patients with influenza-like illness (ILI) and severe acute respiratory infections (SARI) seeking care at sentinel sites and to collect samples from these patients. In December 2020, the National Influenza Centre in Kabul implemented the sequential testing algorithm for these samples recommended in WHO's [interim guidance](#), first testing the samples for influenza, then testing the influenza-negative samples for SARS-CoV-2. Since then, SARS-CoV-2 has been detected in influenza-negative samples. Simultaneously, influenza B viruses have also been detected among sentinel samples indicating the likely community circulation of seasonal influenza as typically occurs in Afghanistan at this time of the year. The country plans to initiate the reporting of this information on COVID-19 testing of sentinel samples to the regional influenza data platform, [EMFLU](#), as they have been doing for influenza on a regular basis for many years.
- In April 2020, **Bhutan** developed a web-based, integrated influenza/COVID-19 surveillance reporting platform and published guidelines for an integrated [COVID-19 and influenza surveillance system](#) that scaled-up the existing influenza surveillance system to incorporate monitoring of the COVID-19 virus¹. The web-based integrated platform eased the work on healthcare staff on reporting daily ILI, SARI and COVID-19 cases. The number of SARI sites was increased from 11 to 50 hospitals and the number of ILI sites was increased from 7 to 186 health facilities. The laboratory network was also expanded to include SARS-CoV-2 testing centers, which has benefited influenza surveillance by ensuring a more regular supply of resources for testing samples for influenza as well. The data generated from integrated surveillance have been used to detect cases of both influenza and COVID-19 in the community, to monitor trends in both viruses and to provide epidemiological information in support of timely prevention and containment measures. Results of the integrated epidemiological and virological surveillance is published in the Weekly COVID-19 integrated Flu view and are being shared to relevant stakeholders, including COVID-19 task force, for evidence-based decision making within the country and for sharing information globally².
- In **Cambodia**, COVID-19 surveillance was integrated into existing influenza surveillance in March 2020, whereby all ILI and SARI cases at sentinel sites are tested for SARS-CoV-2 and influenza. Influenza samples collected in December 2019 were also retrospectively tested for COVID-19. Since March 2020, no COVID-19 cases have been detected among sentinel ILI and SARI cases giving confidence to the assessment that only sporadic cases of COVID-19 are occurring and there is no community transmission of SARS-CoV-2 in the country. ILI surveillance data are an important component of multisource surveillance, where data from multiple sources are used to assess the current epidemiological situation in the country, and support decision making for the COVID-19 response. Maintaining strong influenza surveillance throughout the pandemic was also critical to detect and respond to eight clusters of influenza A(H3N2) infections in various community and closed settings since August 2020.

- In Europe, countries are increasingly integrating SARS-CoV-2 into existing sentinel surveillance schemes in both primary and secondary care. **Albania**, for example, has adapted its existing SARI surveillance systems to monitor both influenza and COVID-19³. Additionally, in Europe, the excess weekly all-cause mortality monitoring was established to provide near real-time estimates of the impact of seasonal influenza. These systems have provided important insights into the mortality impact temporally associated with COVID-19 circulation⁴.

Special Focus: SARS-CoV-2 sero-epidemiology in Kenya

Solidarity II is a global collaboration led by WHO that promotes the implementation of serological surveys of SARS-CoV-2 (For more details, please see [Weekly Epidemiological Update published on 27 January 2021](#), and ["Solidarity II" global serologic study for COVID-19](#)). It provides a collaborative environment for public health agencies and academic institutions around the world to work together and hosts a weekly open forum to discuss recent findings in COVID-19 sero-epidemiological research. Every week over 100 investigators from public health agencies and academic institutions join to discuss the recent research progress, debate the scientific challenges and how to collaboratively solve them. On 26 February 2021, Solidarity II hosted the Kenya Medical Research Institute (KEMRI)-Wellcome Trust Research Programme (KWTRP), who gave a series of presentations on the sero-epidemiology of SARS-CoV-2 in Kenya.

Below we provide an update on the dynamics of SARS-CoV-2 infection across Kenya estimated in blood transfusion donors, seroprevalence in antenatal care screening, health care workers and truck drivers.

The laboratory of KEMRI participated in the [WHO Inter-lab study](#) to establish a WHO International Standard and Reference Panelⁱ. All of the presented studies are based on an in-house ELISA conducted at the KWTRP in Kilifi, Kenya. The assay uses an adaptation of the Krammer ELISA, previously presented at Solidarity II, to measure SARS-CoV-2 anti-Spike antibodies. [The assay](#) readout was optimized to selectively differentiate between those previously infected with SARS-CoV-2 and non-infected individuals. This assay was validated using over 900 locally-acquired serum/plasma samples from 2011-2018 with a specificity of 99%. Sensitivity was estimated to be 92.7%ⁱⁱ based on 179 PCR samples taken at least 7 days after a positive COVID-19 PCR test in Nairobi.

At the request of the Kenyan Government, the KWTRP developed protocols for sampling blood donors, attendees at antenatal care clinics (ANC), health care workers (HCW) and truck drivers at different settings across the country. The seroprevalence results ranged from 9 – 50% in the different populations at different time periods, these are summarised (Figure 3) in relation to the period of sampling and the cumulative number of PCR positive cases identified in Kenya.

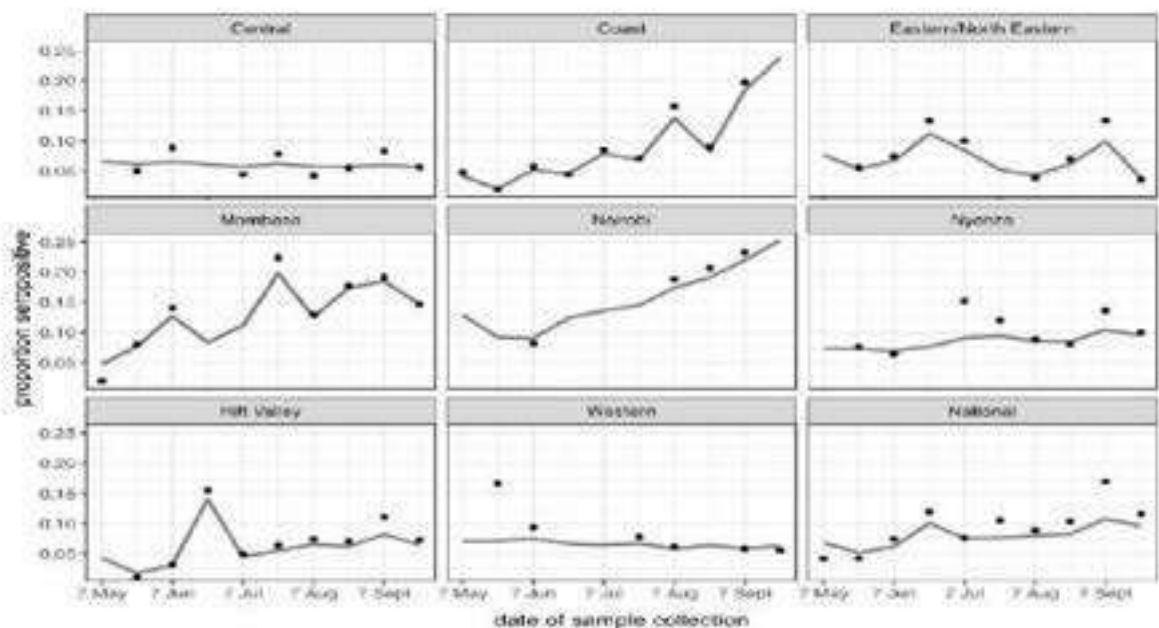

Figure 3: Cumulative confirmed COVID-19 cases per million population in Kenya and time point of the seroprevalence studies

The black line and y-axis represents the national cumulative incidence per 1 million population; each box represents the duration of the studies (the sampling period); the populations studied and the seroprevalence estimate. The vertical lines represent the midpoint for sampling dropping to the cumulative incidence curve.

A study of blood transfusion donors sampled nearly 10 000 donors from sites across the entire countryⁱⁱⁱ. Results were statistically adjusted on age, sex and region to the population structure of Kenya as well as being adjusted for assay test performance. Figure 4 illustrates the unadjusted estimates (dots) and the statistical model estimates for seroprevalence in eight regions and nationally. There is a marked rise in prevalence in the Nairobi and Coast regions throughout the first wave (March to September 2020) with a slightly earlier peak in Mombasa. At the end of the first wave, approximately one in ten Kenyans is estimated to have antibodies to SARS-CoV-2 and this rises to one in five in the major cities, Nairobi and Mombasa. Based on the estimates from the cumulative incidence in Kenya, approximately two in 1000 Kenyans have been confirmed as PCR positive COVID-19 cases in the same time period.

Figure 4: Seroprevalence estimates over time in eight regions and nationally in Kenya, May - September 2020

In August 2020, seroprevalence in 196 expectant mothers in Nairobi was estimated at 50% after adjustment for assay sensitivity and specificity^{iv}. In 419 mothers in Kilifi (Coast region), seroprevalence rose from 1.3% in September to 11.0% in November. Seroprevalence estimates in nearly 700 HCW varied geographically; in urban Nairobi in August, seroprevalence was 43.8% while in rural Kilifi and Busia in November, it was 11.9% and 12.6%, respectively. There was no association between health service role and seroprevalence suggesting that the cumulative incidence in HCWs was driven more by the community prevalence than by hospital-based risk. Truck drivers provide essential services in the pandemic and are subject to mandatory PCR testing every two weeks. Among 830 truck drivers, seroprevalence was 42.3% in October, varying little between the Coast Region (45.2%) and two sites in Busia in the Western Region (36.0%, 47.9%)^v. This illustrates a challenge in pandemic control where mobility of essential workers is necessary to support movement restrictions of the rest of the population.

All studies mentioned were conducted before the second wave (October 2020 to January 2021) of cases in Kenya. When viewing these results as estimates of cumulative incidence, they illustrate substantial under-ascertainment of infections by PCR testing. Additionally, the study in blood donors illustrates large regional heterogeneity in infection with much higher cumulative incidence in the cities.

Additional SARS-CoV-2 seroprevalence studies are ongoing in Kenya with support from WHO (Unity Studies). More information about WHO's work on SARS-CoV-2 seroepidemiology can be found [here](#).

Special Focus: Update on SARS-CoV-2 Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available.

Further information on the background of the variants of concern (VOCs) is available from previously published editions of the [Weekly Epidemiological Update](#). Here we provide an update on ongoing studies and the geographical distribution of select VOCs as reported by countries, territories and areas (hereafter countries) as of 9 March 2021.

Results of ongoing studies of VOCs are summarized in Table 2 below. While many countries worldwide are currently experiencing a decline in overall SARS-CoV-2 infections, likely as a result of the public health and social measures (PHSM) implemented, an increased number of reports of variants have been noted in a number of countries. As surveillance activities at local and national levels are strengthened, including systematic genomic sequencing to detect cases infected with SARS-CoV-2 variants, the number of countries reporting VOCs has continued to increase (Table 2, Figures 5, 6 and 7, Annex 2). This information should be interpreted with due consideration of limitations of ongoing surveillance, including but not limited to differences between countries in sequencing capacity and which samples are prioritized for sequencing. WHO continues to advocate for strengthening surveillance and sequencing capacity, and a systematic approach to provide a representative indication of the extent of variant transmission. New potential variants of interest (VOIs) or VOCs are currently under review and may be added to future updates.

Table 3: Overview of emerging information on key variants of concern, as of 9 March 2021*

Nextstrain clade	20I/501Y.V1	20H/501Y.V2 [†]	20J/501Y.V3
PANGO lineage	B.1.1.7	B.1.351	B.1.1.28.1, alias P.1 [†]
GISAID clade	GR	GH	GR
Alternate names	VOC 202012/01 [†]	VOC 202012/02	-
First detected by	United Kingdom	South Africa	Brazil / Japan
First appearance	20 September 2020	Early August 2020	December 2020
Key spike mutations	H69/V70 deletion; Y144 deletion; N501Y; A570D; and P681H	L242/A243/L244 deletion; K417N E484K, N501Y	K417N, E484K; N501Y
Key mutation in common	S106/G107/F108 deletion in Non-Structural Protein 6 (NSP6)		
Transmissibility*	Increased ¹ (36%-75%) ² , increased secondary attack rate ³ (10% to 13%)	Increased [1.50 (95% CI: 1.20-2.13) times more transmissible than previously circulating variants] ^{4, 5}	Increased, more transmissible than previous circulating variants ⁶
Severity*	Possible increased risk of hospitalization ⁷ , severity and mortality ³	No impact reported to date ^{4, 5} , no significant change in-hospital mortality ⁸	Under investigation, limited impact ⁶
Neutralization capacity*	Slight reduction but overall neutralizing titers still remained above the levels expected to confer protection ⁹	Decreased, suggesting potential increased risk of reinfection ^{4, 10, 11}	Decreased, reinfections reported ¹²⁻¹⁴
Potential impacts on vaccines*	No significant impact on Moderna, Pfizer-BioNTech, and Oxford-AstraZeneca vaccines ¹⁵⁻¹⁸	Moderna and Pfizer-BioNTech: Reduction in the neutralizing activity, but impact on protection against disease not known. ¹⁵⁻¹⁸ Novavax and Janssen: Lower vaccine efficacy in South Africa compared to settings without the variant (press release data only). Moderate-severe disease were assessed. Serologic neutralization results pending. ^{19, 20} AstraZeneca: Limited vaccine efficacy against mild-moderate COVID-19 disease, with wide confidence intervals, impact on severe disease undetermined. Serologic neutralization substantially reduced compared with original strains, based on small number of samples analyzed ^{21, 22}	Under investigation
Potential impacts on diagnostics*	S gene target failure (SGTF). ²¹ No impact on Ag RDTs observed ²³	None reported to date	None reported to date
Countries reporting cases (newly reported in last week)**	111 (5)	58 (3)	32 (3)

[†]While work is ongoing to establish standardized nomenclature for key variants, these are the names by which WHO will refer to them in this publication.

*Generalized findings as compared to non-VOC viruses. Based on emerging evidence from multiple countries, including non-peer-reviewed preprint articles and reports from public health authorities and researchers – all subject to ongoing investigation and continuous revision.

**Includes official and unofficial reports of VOCs detections in countries among either travellers (imported cases only) or community samples (local transmission).

Variant VOC 20212/01

Since our last update on 9 March, VOC 20212/01 has been detected in five additional countries. As of 9 March, a total of 111 countries across all six WHO regions have reported cases of this variant (Figure 5).

Figure 5. Countries, territories and areas reporting SARS-CoV-2 VOC 20212/01 as of 9 March 2021

Variant 501Y.V2

Since the last update on 2 March, 501Y.V2 has been reported from three additional countries –totaling 58 countries across all six WHO regions (Figure 4). In several areas within the African Region, variant 501Y.V2 has been reported to comprise a high proportion of sequenced samples.³⁵

Reductions in neutralizing antibody activity against 501Y.V2 following either natural infection or vaccination have been documented^{4, 24} and discussed in past editions of the [Weekly Epidemiological Update](#). Findings from a recent study that analyzed convalescent plasma from 20 patients and sera from 22 participants of vaccine trials [Moderna SARS-CoV-2 mRNA-1273 vaccine (12 participants); Pfizer BNT162b2 COVID-19 vaccine (10 participants)] indicated that relative to the original SARS-CoV-2, there was a substantial decrease in the neutralizing activity of convalescent plasma (9.4-fold) and sera from vaccinated participants (10.3 to 12.4-fold) against the 501Y.V2 variant.¹⁸

Figure 6. Countries, territories and areas reporting SARS-CoV-2 501Y.V2 as of 9 March 2021

Variant P.1

Since our last update, variant P.1 has been reported in three additional countries. As of 9 March, this variant is reported in 32 countries across all six WHO regions (Figure 5).

Figure 7. Countries, territories and areas reporting SARS-CoV-2 P.1 variant as of 9 March 2021

Brazil has experienced high incidence and mortality due to COVID-19, recording over 11 million cases and 260 000 deaths (as of 7 March 2021); the second highest globally (figure 8). The burden of COVID-19 has been highly variable across the country, with Amazonas State and its capital Manaus, being the most affected⁶. There has been a sharp increase in cases and deaths reported in the month of January, however, both the cases and deaths have slowly started to decline in these states (figure 9), while remaining high or increasing in the country overall.

In a genomic survey conducted from 16 March 2020 to 13 January 2021 in 25 municipalities of Amazonas State, Brazil, several sequences were identified²⁵. Variant P.1, which was first detected in early December 2020 in Manaus in Amazonas state, displayed a rapid increase in prevalence through January 2021; accounting 24% (n=60) of sequences samples included in this study. Additionally, to better understand the emergence of P.1 in the Amazonas State, a real-time PCR assay was performed to detect the deletion at orf1ab (NSP6: S106del, G107del, F108del) – a deletion found in all three VOCs (P.1, B.1.1.7 and B.1.351). Upon evaluating the SARS-CoV-2 positive samples between 1 November 2020 through 31 January 2021 but not sequenced, no sample was found positive for the NSP6 deletion before 16 December, supporting low prevalence of VOC P.1 before mid-December 2020 in Amazonas. However, between mid-December 2020 and January 2021, positive samples with NSP6 deletion were very frequent. Collectively these studies highlight a sharp increase in prevalence of variant P.1 from 0% in November 2020 (n=0/88) to 73% during 1-15 January 2021 (n=119/162).

Figure 8: Weekly COVID-19 cases per 1 million population in Brazil, as of 7 March 2021

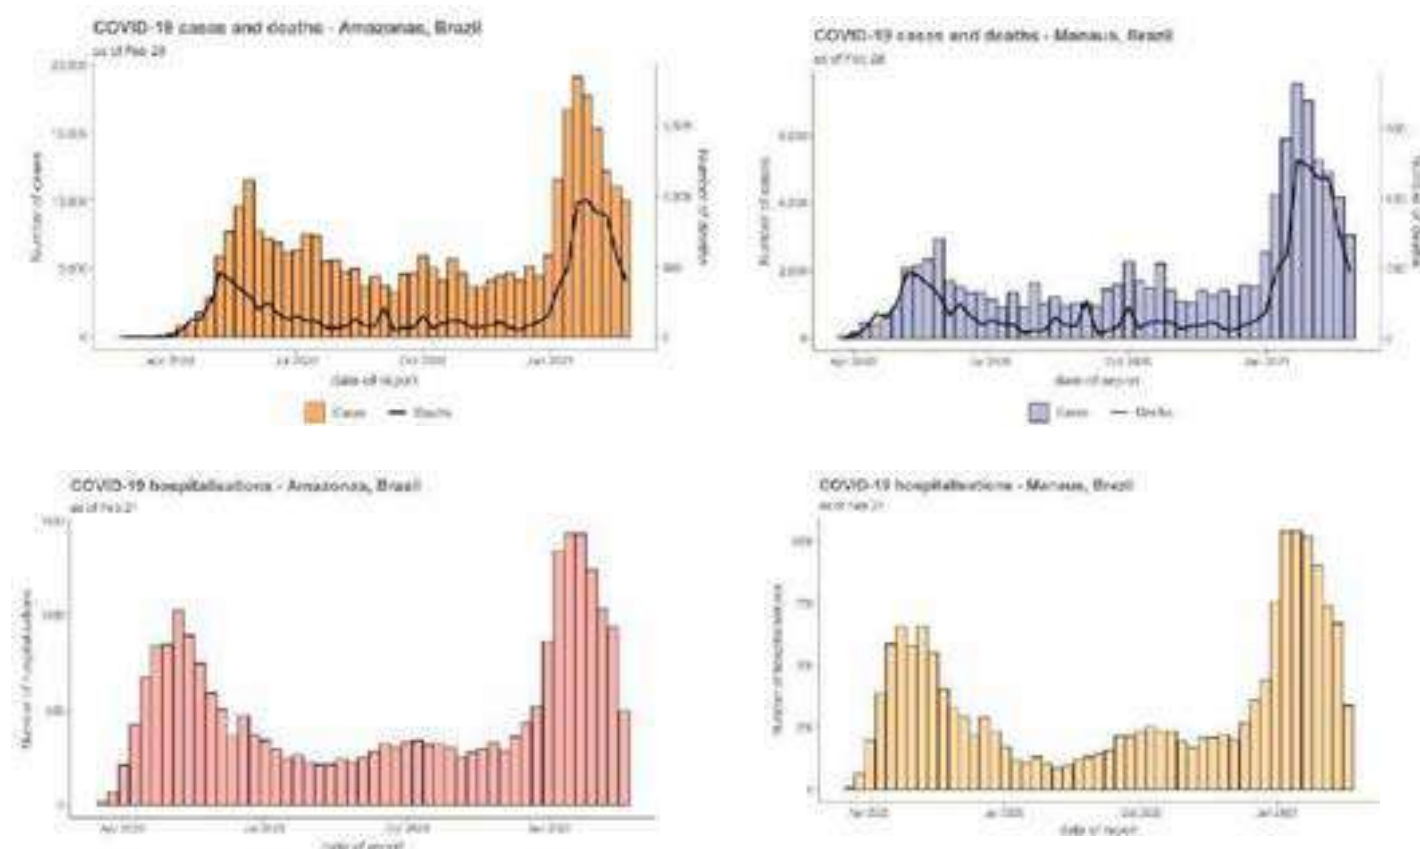

Figure 9: COVID-19 cases, deaths (as of 28 February 2021) and hospitalizations (as of 21 February) in Amazonas and Manaus, Brazil

Source: Ministry of Health Brazil

Based on preliminary investigations in Manaus, where this variant was initially identified, P.1 has shown to have increased transmissibility compared to previously circulating variants. It can evade 25% to 61% protective immunity provided by the previous infection, thereby making people susceptible to reinfection⁶. Additionally, it is 1.1–1.8 times more likely to result in mortality. Researchers have cautioned that these are preliminary findings and the results are not generalizable to other settings. More studies and genome sequencing data are required to assess the transmissibility and severity of variant P.1. It is also important to conduct these studies outside of Manaus as there has been a sharp increase in hospitalizations during the second wave which has resulted in collapsing of health systems in Manaus (figure 9). Therefore, it is difficult to determine the cause of high mortality which could be either due to variant P.1 or collapsed health systems or both.

WHO Recommendations

PHSM remain critically important to curb the spread of SARS-CoV-2, including newly reported variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of physical distancing and other PHSM as well as infection prevention and control measures in health facilities has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations and deaths among COVID-19 patients. Findings from new studies evaluating transmission, severity and impact on medical countermeasures will continue to help inform PHSM and IPC measures employed by Member States. National and local authorities are encouraged to continue strengthening existing PHSM, IPC and disease control activities, including epidemiological surveillance, strategic testing, and systematic sequencing of SARS-CoV-2 where feasible.

If potential VOIs or VOCs are detected, Member States are requested to inform WHO through established WHO Country or Regional Office reporting channels, submit genome sequences to publicly available databases (e.g., GISAID), and perform field and laboratory investigations (where appropriate) to improve understanding of potential impacts. For further information on see: [Proposed working definitions for SARS-CoV-2 variants of interest and variants of concern](#).

WHO regional overviews

African Region

The Africa region reported over 55 000 new cases and over 1300 new deaths, a 10% increase and 16% decrease respectively compared to the previous week. Since new weekly case counts peaked in early January 2021, this is the first weekly increase following 6 weeks of decreasing case numbers. The highest numbers of new cases were reported from South Africa (7981 new cases; 13.5 new cases per 100 000 population; a 19% decrease), Ethiopia (6976 new cases; 6.1 new cases per 100 000; a 13% increase), and Zambia (4840 new cases; 26.3 new cases per 100 000; a 48% increase).

The highest numbers of new deaths were reported from South Africa (706 new deaths; 1.2 new deaths per 100 000 population; a 30% decrease), Ethiopia (66 new deaths; 0.1 new deaths per 100 000; a 21% decrease), and Nigeria (59 new deaths; <0.1 new deaths per 100 000; a 20% decrease).

Region of the Americas

The Region of the Americas reported over 1.1 million new cases and over 32 000 new deaths, a 2% and 4% decrease respectively compared to the previous week. The highest numbers of new cases were reported from the United States of America (427 233 new cases; 129.1 new cases per 100 000; a 10% decrease), Brazil (413 597 new cases; 194.6 new cases per 100 000; an 11% increase), and Argentina (42 517 new cases; 94.1 new cases; a 14% decrease). The United States and Brazil accounted for 76% of new weekly cases reported in the Americas.

The highest numbers of new deaths were reported from the United States of America (12 315 new deaths; 3.7 new deaths per 100 000; a 17% decrease), Brazil (9935 new deaths; 4.7 new deaths per 100 000; a 23% increase), and Mexico (5104 new deaths; 4.0 new deaths per 100 000; a 7% decrease).

Eastern Mediterranean Region

The Eastern Mediterranean region reported just under 229 000 new cases and just under 2800 new deaths, a 10% and 9% increase respectively compared to the previous week. New cases have increased week on week for the past four weeks, while deaths have increased for the past two weeks. The highest numbers of new cases were reported from Islamic Republic of Iran (58 523 new cases; 69.7 new cases per 100 000; a 3% increase), Jordan (34 919 new cases; 342.2 new cases per 100 000; a 31% increase), and Iraq (30 948 new cases; 76.9 new cases per 100 000; a 13% increase).

The highest numbers of new deaths were reported from Islamic Republic of Iran (614 new deaths; 0.7 new deaths per 100 000 population; an 8% increase), Lebanon (361 new deaths; 5.3 new deaths per 100 000; a 2% increase), and Pakistan (329 new deaths; 0.1 new deaths per 100 000; a 20% increase)

European Region

The European region reported over 1.1 million new cases and under 21 000 new deaths, a 4% increase and 6% decrease respectively compared to the previous week. Since early January 2021, new weekly cases have decreased overall; however, increases have been reported in the past two weeks. New weekly deaths have continued to decline since the mid-January 2021. The highest numbers of new cases were reported from France (143 622 new cases; 220.0 new cases per 100 000; a 4% decrease), Italy (138 937 new cases; 229.8 new cases per 100 000; a 24% increase), and Poland (87 928 new cases; 232.3 new cases per 100 000; a 29% increase).

The highest numbers of new deaths were reported from the Russian Federation (2978 new deaths; 2.0 new deaths per 100 000; a 5% increase), France (2100 new deaths; 3.2 new deaths per 100 000; a 3% decrease), and Italy (2071 new deaths; 3.4 new deaths per 100 000; a 3% increase).

South-East Asia Region

The South-East Asia region reported over 167 000 new cases and 2200 new deaths, a 2% and 32% decrease respectively compared to the previous week. Progressive declines in case incidence observed mid-September 2020 have slowed in recent weeks, and increases have been observed in several countries in the region. The highest numbers of new cases were reported from India (114 068 new cases; 8.3 new cases per 100 000; a 9% increase), Indonesia (44 762 new cases; 16.4 new cases per 100 000; a 23% decrease), and Bangladesh (3893 new cases; 2.4 new cases per 100 000; a 39% increase).

The highest numbers of new deaths were reported from Indonesia (1173 new deaths; 0.4 new deaths per 100 000; a 30% decrease), India (705 new deaths; <0.1 new deaths per 100 000; a 6% decrease), and Nepal (237 new deaths; 0.8 new deaths per 100 000; a 67% decrease). The spike in deaths observed last week were driven by retroadjustments in Nepal.

Western Pacific Region

The Western Pacific region reported over 41 000 new cases and over 600 new deaths, a 6% and 20% decrease respectively compared to the previous week. New weekly cases have continued to decrease since mid-January 2021, and deaths have decreased overall in recent weeks. The highest numbers of new cases were reported from Philippines (16 891 new cases; 15.4 new cases per 100 000; a 13% increase), Malaysia (13 462 new cases; 41.6 new cases per 100 000; a 25% decrease), and Japan (7216 new cases; 5.7 new cases per 100 000; similar to the previous week).

The highest numbers of new deaths were reported from Japan (367 new deaths; 0.3 new deaths per 100 000; a 17% decrease), Philippines (176 new deaths; 0.2 new deaths per 100 000; a 20% decrease), and Malaysia (45 new deaths; 0.1 new deaths per 100 000; a 36% decrease).

Key weekly updates

WHO Director-General key message

Governments and individuals must remember that vaccines alone will not keep up safe. Basic public health measures remain the foundation of the response.

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 28 February 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: COVID-19 trade, travel and points of entry](#)
- [Special focus: the importance of fit, filtration and breathability of non-medical \(fabric\) masks in the context of COVID-19](#)
- [Special focus: SARS-CoV-2 variants of concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

Over 2.6 million new cases were reported last week, a 7% increase compared to the previous week, following six consecutive weeks of declining numbers (Figure 1). The global case increase was driven by increases in the Eastern Mediterranean (14%), South-East Asia (9%), Europe (9%) and the Americas (6%). Possible reasons for this increase include the continued spread of more transmissible variants of concern (VOCs), relaxation of public health and social measures (PHSM) and fatigue around adhering to PSHM measures. Basic public health measures remain the foundation of the response. For public health authorities, that means testing, contact tracing, isolation, supported quarantine and quality care. For individuals, it means avoiding crowds, physical distancing, hand hygiene, masks and ventilation. Furthermore, immunity conferred by vaccination takes weeks at the individual level, and it may take longer to observe impacts at the population-level.

Figure 1. COVID-19 cases reported weekly by WHO Region, and global deaths, as of 28 February 2021**

**See [Annex: Data, table and figure notes](#)

The number of global new deaths continues to decrease, with over 63 000 new deaths reported last week, a 6% decrease as compared to the previous week. New deaths decreased in four regions, Europe, Africa the Western Pacific, and the Americas (by 15%, 19%, 35% and 1%, respectively), and increased by 47% in the South East Asia Region, partly due to retrospective reporting of deaths from Nepal. The Americas reported over 1.1 million new cases and nearly 34 000 deaths, which accounted for 42% of global cases and 53% of global deaths.

In the past week, the five countries reporting the highest number of new cases were the United States of America (472 904 new cases, a 2% decrease), Brazil (373 954 new cases, a 18% increase), France (149 959 new cases, a 14% increase), Italy (112 029 new cases, an 32% increase) and India (105 080 new cases, a 21% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 28 February 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)

Figure 2. COVID-19 cases per 100 000 population reported in the last seven days by countries, territories and areas, 22 February through 28 February 2021**

**See [Annex: Data, table and figure notes](#)

Special Focus: COVID-19 and international trade, travel and points of entry

The COVID-19 pandemic has had, and is having, a substantial impact on international trade and travel. In 2020, world passenger traffic fell by 2.7 billion passengers, or by 60% compared to 2019, causing a US\$ 371 billion loss of gross passenger operating revenues of airlines¹. In addition to the economic loss, travel restrictions are also having a direct impact on the lives and livelihoods of transport workers, most notably in the maritime sector. The International Maritime Organization (IMO) estimates that around 400 000 seafarers have been stranded on board commercial vessels, long past the expiry of their contracts and unable to be repatriated. A similar number of seafarers urgently need to join ships to replace these individuals².

WHO has been engaging with and supporting stakeholders in the travel sector across all points of entry (airports, ports, and ground crossings) since the start of the pandemic, and produced its first travel-related guidance in March 2020. All guidance documents can be found [here](#).

Managing the safe and effective recovery of international travel through a risk-based approach

To promote a safe and effective gradual recovery of international travel while managing the public health risks associated with the cross-border movement of people and goods, key stakeholders – including Member States, the travel industry and its affiliates, and the general public – requested further guidance from WHO on how to implement a risk-based approach to international travel. This was also echoed in the advice to WHO by the IHR (2005) Emergency Committee for COVID-19 at both its [fifth meeting](#) in October 2020, and its [sixth meeting](#) in January 2021.

In December 2020, WHO published [guidance](#) for national authorities on a step-by-step approach to decision-making for calibrating public health risk mitigation measures for international travel in the context of COVID-19. It is divided into three main sections: risk assessment, risk mitigation and risk communication. Key points include:

- During the COVID-19 pandemic, international travel should always be prioritized for emergencies and humanitarian actions, travel of essential personnel, repatriations, and cargo transport for essential supplies such as food, medicines, and fuel;
- As countries gradually resume international travel, introduction of risk mitigation measures aiming to reduce travel associated exportation, importation and onward transmission of SARS-CoV-2 should not unnecessarily interfere with international traffic and should be based on a thorough risk assessment that is conducted systematically and routinely;
- Decision-makers in Member States can conduct risk assessments through a mixed-method approach (explained in the guidance and the accompanying [risk assessment tool](#)) to calculate the additional burden presented by possible importation of COVID-19 cases and decide policies on the basis of whether they have the capacity to cope with this burden;
- International travellers should not be considered by nature as suspected COVID-19 cases or contacts. Therefore, WHO does not recommend travellers as a priority group for testing;
- The use of “immunity certificates” for international travel in the context of COVID-19 is not currently supported by scientific evidence and is therefore not recommended by WHO; and
- The overall health and well-being of communities should be at the forefront of considerations when deciding on and implementing international travel-related measures.

COVID-19 diagnostic testing in the context of international travel

To limit transmission and reduce morbidity and mortality from COVID-19, countries around the globe have implemented public health and social measures (PHSM) for epidemic control. One measure considered by many countries and transport sector stakeholders is testing for SARS-CoV-2 in international travellers prior to travel, at points of entry or after travel. In addition to the risk-based travel guidance, WHO has published a [scientific brief on diagnostic testing](#), examining the requirements and issues around testing as a tool for mitigating cross-border transmission of SARS-CoV-2. It provides an overview of SARS-CoV-2 diagnostic assays and their performance and suitability for potential use in SARS-CoV-2 testing prior to departure, at points of entry and on arrival. It also raises the following key points:

- Testing at borders is not a substitute for other public health measures, especially robust contact tracing systems;
- WHO recommends that confirmed, probable and suspected cases for COVID-19 and contacts of confirmed or probable cases do not travel. WHO also advises that travellers who are unwell or any persons who are at an elevated risk for developing severe disease and dying from SARS-CoV-2 infection, including people 60 years of age or older or those with chronic diseases or underlying health conditions, delay or avoid travelling internationally to and from areas with COVID-19 community transmission; and
- A thorough risk assessment should be a key element of the decision-making process regarding SARS-CoV-2 testing policies for international travellers. Additionally, resources and capacity to offer testing for international travellers should be assessed critically to avert negative impact on testing in high-risk settings and high-risk groups.

Impact of new variants of concern on international travel restrictions

As [previously reported](#), evidence suggests that some newly identified variants of concern may have increased transmissibility as compared to previously circulating variants. It is likely that there will continue to be elevated risks of the exportation and importation of cases between countries via international travel, including cases of the new variants of concern. The impact on countries will depend on multiple factors including their epidemiological situation, the capacity of their health systems, and the implementation of other public health and social measures, as explained in the [WHO risk-based travel guidance](#).

Any measures imposed to prevent the importation of SARS-CoV-2 variants of concern must, therefore, be time limited; not prejudiced towards countries readily sequencing and sharing findings; based on thorough assessments of risk; and continuously adapted to emerging information.

Considerations regarding COVID-19 vaccination for international travellers

Following the advice of the IHR (2005) Emergency Committee for COVID-19 after its sixth meeting in January 2021, WHO published an [interim position paper](#) on considerations regarding proof of COVID-19 vaccination for international travellers. At the present time, national authorities and conveyance operators should not introduce requirements of proof of COVID-19 vaccination for international travel as a condition for departure or entry, given that there are still critical unknowns regarding the efficacy of vaccination in reducing transmission; duration of protection offered by vaccination; whether vaccination offers protection against asymptomatic infection; and possible exemption of people who have antibodies against SARS-CoV-2. In addition, considering that there is limited availability of vaccines, preferential vaccination of travellers could result in inadequate supplies of vaccines for priority populations considered at high risk of severe COVID-19. WHO also recommends that people who are vaccinated should not be exempt from complying with other travel risk-reduction measures. Should the requirement of proof of COVID-19 vaccination for international travellers be introduced in the future in accordance with IHR provisions, vaccines must be approved by WHO, be of suitable quality and universally available.

WHO is working with partners to establish a governance framework and specifications for a digital vaccination certificate for possible use at both national and international levels. Regardless of any technology implemented in the future, the COVID-19 vaccination status of international travellers should be recorded

through the International Certificate for Vaccination and Prophylaxis based on the model presented in Annex 6 of the IHR. The same format could be adapted once WHO pre-qualified COVID-19 vaccines become universally available, and relevant recommendations are provided under the IHR.

Systematically reviewing the evidence available to inform and update WHO's travel guidance

WHO commissioned a systematic review, with support from the Cochrane collaboration, on the evidence available up to June 2020 on the effectiveness of travel measures on reducing international transmission of COVID-19³. Subsequently, since October 2020, WHO has been convening the [International Travel and Health Guideline Development Group](#) (ITH GDG) to develop guidance documents based on systematic reviews of the evidence available on the efficacy, safety and harms of specific public health interventions for the mitigation of SARS-CoV-2 transmission before, during and after travel. The ITH GDG is currently focusing on air travel, which will be followed by maritime travel and travel via land.

The first publication, [Evidence to recommendations: COVID-19 mitigation in the aviation sector](#), describes the methodological approaches underpinning the work of the ITH GDG and presents an analytic framework that will inform interim guidance and recommendations. It presents the nine questions being addressed, which relate to infection prevention and control (IPC), health screening, quarantine and isolation, testing, contact tracing, risk communication and restriction of air travel, among others.

The second publication, [Evidence to recommendations: Methods used for assessing health equity and human rights considerations in COVID-19 and aviation](#), describes the process that WHO is undertaking to assess the reporting of key factors related to health equity and human rights in the primary literature of specific public health interventions as they relate to COVID-19 and aviation. Guidance documents to address these nine questions are currently being developed, using the methodologies described in these documents and will be published in the coming weeks.

³ Cochrane (2020). Cochrane Rapid Review examines travel-related control measures to contain the COVID-19 pandemic.

Special Focus: The importance of fit, filtration and breathability of non-medical (fabric) masks in the context of COVID-19

Since January 2020, WHO has recommended the use of masks as part of a [comprehensive set of interventions to prevent the spread of SARS-CoV-2](#). There are many commercial non-medical (also called fabric or cloth) masks available; however, the multitude of voluntary international standards together with the absence of regulatory oversight has made it difficult for people to know if their masks are effective barriers.

When implemented with other public health and social measures, a mask can serve as an effective barrier to prevent transmission of the SARS-CoV-2 virus, provided that it fits well, has good filtration, and the wearer can easily breathe through it (Figure 3). When any of these three parameters are not optimized, the mask may be an ineffective barrier and/or uncomfortable to wear.

Figure 3. Illustration of the three essential parameters of filtration, breathability and fit

Good fit means the mask fully covers the nose, mouth and chin. There should be no leaks around the edges of the mask. The exhaled breath should be filtered through the surface of the mask.

Good filtration means the mask has the right fabric or combination of fabrics that filter droplets present in exhaled air.

Good breathability means the wearer can easily breathe through the material of the mask. Since masks are often rated in terms of their filtration, it is equally important to maximize breathability to ensure the wearer's comfort.

WHO first issued [guidance](#) on the composition of non-medical or fabric masks in June 2020 providing specific recommendations about the number of layers, their composition and performance, and the importance of fit. Where possible, to ensure adequate wearer comfort, the design and combination of textiles used in manufacturing the fabric masks should be independently tested for adequate fit, filtration and breathability. This is especially important for masks used for an extended period of time and/or in humid environments.

WHO continues to encourage governments to establish regulations for non-medical masks, and has published evidence-based recommendations on what to look for when purchasing a fabric mask, which are summarized below:

When purchasing a fabric mask, check the packaging for information that they have been laboratory tested:

- At least 70% filtration of particles or droplets measuring three microns (lower filtration is acceptable if the challenge particles/droplets are smaller);
- No more than 60 pascals of pressure difference per square centimetre (<60 Pa/cm²) (alternative measures such as air permeability or airflow resistance may be used);
- Guaranteed at least five cycles of washing with no performance reduction;
- No exhalation valves;
- Antimicrobial coatings or treatments are not required; if included, the treated layers must be away from the skin and be tested for inhalational and skin safety as per the [ISO](#) or [REACH](#) regulation requirements.

If there are no standards listed on the package, find a mask that has three layers, made up of:

- Inner layer made of absorbent cotton;
- Middle layer made of a non-woven spunbond polypropylene (i.e., a filter layer); and
- Outer layer made of a moisture resistant polyester or another layer of non-woven spunbond polypropylene.

More detailed information can be found in the annex section of the [guidance document](#). Breathability may be altered when additional layers are added to increase filtration. For example, adding a second mask over the first may increase filtration and fit, but can also make breathing more difficult and uncomfortable. If people have to take off a mask to breathe, the barrier is naturally lost.

Finally, a non-medical/fabric mask should always be stored properly in designated plastic bags or containers before and after use and should be cleaned daily when used, with soap or detergent and preferably hot water (60 degrees). If hot water is not available, wash the mask with soap or detergent using water at room temperature followed by boiling the mask for one minute.

Single use masks should always be disposed of properly, preferably into a closed bin after use. Masks should never be left out after use, as used masks may contain virus which may be transmitted to the wearer or others.

WHO continues to closely monitor masks that are being developed by industry, and encourages research into textile combinations and innovative designs that maximize fit, filtration, breathability and overall comfort. Consultations with scientists, ministries of health and public health institutions continue, and updates will be provided as the science in this field evolves.

For complete information on the selection of a mask, how to wear and maintain it, visit the [WHO mask webpage](#).

WHO technical guidance for mask use in the context of COVID-19 can be found [here](#).

Special Focus: Update on SARS-CoV-2 Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available. Further information on the background of the variants of concern (VOC) is available from previously published [Disease Outbreak News](#) and recent publications of the [Weekly Epidemiological Update](#). Here we provide an update on the geographical distribution of three VOCs as reported by countries, territories and areas (hereafter countries) as of 2 March 2021 ([Table 2](#), [Annex 2](#)). This information should be interpreted with due consideration of limitations of ongoing surveillance, including but not limited to differences between countries in sequencing capacity and which samples are prioritized for sequencing. WHO continues to advocate for strengthening surveillance and sequencing capacity, and a systematic approach to provide a representative indication of the extent of variant transmission. New potential variants of interest (VOIs) or VOCs are currently under review and may be added to future updates.

Although many countries worldwide are currently experiencing a decline in overall SARS-CoV-2 infections likely as a result of the public health and social measures (PHSM) implemented and various vaccination programme implementations, there has been an increased number of reports of variants which are of concern. Many countries across all six WHO regions have started to report increases in new cases of COVID-19 in the past month, while it is difficult to ascertain the exact proportion of all new cases which may be attributable to VOIs and VOCs, summaries on the past week's updates on VOC 202012/01, 501Y.V2 and P.1 variants of concern are outlined below.

Table 2: Key characteristics of circulating variants of concern (as of 1 March 2021)*

Nextstrain clade	20I/501Y.V1	20H/ 501Y.V2[†]	20J/501Y.V3
PANGO lineage	B.1.1.7	B.1.351	B.1.1.28.1, alias P.1[†]
GISAID clade	GR	GH	GR
Alternate names	VOC 202012/01[†]	VOC 202012/02	-
First detected by	United Kingdom	South Africa	Brazil / Japan
Earliest sample date	20 September 2020	Early August 2020	December 2020
Key spike mutations	<ul style="list-style-type: none"> • N501Y • D614G • A570D • P681H • H69/V70 deletion • Y144 deletion 	<ul style="list-style-type: none"> • N501Y • D614G • E484K • K417N • L242/A243/L244 deletion 	<ul style="list-style-type: none"> • N501Y • D614G • E484K • K417N
Key mutation in common	S106/G107/F108 deletion in non-structural protein 6 (nsp6)		
Number of countries reporting cases (newly reported in last week)**	106 (5)	56 (5)	29 [‡] (1)

* A more detailed version of this table is available in the [previous Weekly Epidemiological Update](#), and an updated version will be available in the next issue.

[†] While work is ongoing to establish an easy-to-pronounce and non-stigmatizing nomenclature for VOIs and VOCs, these are the names by which they will be referred to in this publication.

** Includes official and unofficial reports of VOCs detected in countries among travellers (imported cases) or community-based samples.

[‡] One country was removed and another added this week, resulting in the same total as reported in 23 February update

Proposed working definitions for SARS-CoV-2 VOIs and VOCs

As a supplement to last week's issue, a special edition was published with an overview of the [working definitions for SARS-CoV-2 variants of interest and variants of concern](#), and the associated actions WHO will take to support Member States, their national public health institutes and reference laboratories, along with the recommended actions Member States should take. These definitions will be reviewed regularly and updated as necessary.

VOC 20212/01

Since our last update on 23 February, VOC 20212/01 has been detected in five additional countries. As of 2 March, a total of 106 countries across all six WHO regions have reported cases of this variant (Figure 4). Community transmission has been reported in at least 42 countries across four WHO regions, noting that transmission classification is currently incomplete for 35 (33%) countries reporting this variant.

Figure 4. Countries, territories and areas reporting VOC 20212/01, as of 2 March 2021

501Y.V2

Since the last update on 23 February, 501Y.V2 has been reported from five additional countries – now totalling 56 countries across all six WHO regions (Figure 5). Community transmission of 501Y.V2 has been reported in eight countries across three WHO regions, noting the transmission classification is currently incomplete for 42 (75%) countries reporting this variant.

Figure 5. Countries, territories and areas reporting 501Y.V2, as of 2 March 2021

P.1

Since our last update, one country has corrected their reporting, and reporting from another amounted to one additional country. To date, this variant is reported in 29 countries across all six WHO regions (Figure 6). Community transmission of P.1 has been reported in at least three countries in one WHO region, noting the transmission classification is currently incomplete for nine (31%) countries reporting this variant.

Figure 6. Countries, territories and areas reporting P.1, as of 2 March 2021

WHO regional overviews

African Region

In the past week, the African Region reported over 50 000 new cases and 1500 new deaths, a 24% and 19% decrease respectively compared to the previous week. This represents the largest decline as a percentage in new cases and the second largest decline of new deaths globally. In the region new cases in the past week rose in 17 of 49 (36%) countries and fell in 30 of 49 (64%). This week new deaths increased in 13 of 49 (28%) countries and declined in 24 of 49 (53%).

The highest numbers of new cases were reported in South Africa (9858 new cases; 16.6 new cases per 100 000 population; a 20% decrease), Ethiopia (6196 new cases; 5.4 new cases per 100 000; a 1% increase), and Nigeria (3864 new cases; 1.9 new cases per 100 000; a 34% decrease). The same countries reported the highest number of new deaths in the past week: South Africa (1001 new deaths; 1.7 new deaths per 100 000; an 11% decrease), Ethiopia (83 new deaths; 0.1 new deaths per 100 000; an 8% decrease), and Nigeria (74 new deaths; <0.1 new deaths per 100 000; a 12% decrease).

Region of the Americas

Over 1.1 million new cases and just under 34 000 new deaths were reported in the Region of the Americas this week, a 6% increase and 1% decrease respectively compared to the previous week. This represents the first rise in new cases since the week ending 10 January. This week, new cases rose in 22 of 56 (39%) countries and fell in 24 of 56 (43%). This week, new deaths increased in 11 of 56 (20%) countries and declined in 20 of 56 (36%).

The highest numbers of new cases were reported from the United States of America (472 904 new cases; 142.9 new cases per 100 000 population; a 2% decrease), Brazil (373 954 new cases; 175.9 new cases per 100 000; an 18% increase) and Argentina (49 516 new cases; 109.6 new cases per 100 000; a 50% increase). The highest numbers of new deaths were reported from the United States of America (14 866 new deaths; 4.5 new deaths per 100 000; a 1% increase), Brazil (8070 new deaths; 3.8 new deaths per 100 000; an 11% increase), and Mexico (5509 new deaths; 4.3 new deaths per 100 000; a 14% decrease).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 207 000 new cases, a 14% increase compared to last week. The region reported just over 2500 new deaths, a 5% increase. Across the region 14 of 22 (64%) countries reported increases in new cases and 8 of 22 (36%) declined this week. New deaths rose in 13 of 22 countries (59%) and fell in 7 of 22 (32%).

The three countries reporting the highest numbers of new cases this week were the Islamic Republic of Iran (57 078 new cases; 68 new cases per 100 000 population; a 3% increase), Iraq (27 491 new cases; 68.3 new cases per 100 000; a 19% increase) and Jordan (26 685 new cases; 261.5 new cases per 100 000; a 78% increase). The highest numbers of new deaths this week have been reported in the Islamic Republic of Iran (571 new deaths; 0.7 new deaths per 100 000 population; a 9% increase), Lebanon (355 new deaths; 5.2 new deaths per 100 000; a 6% increase) and Egypt (341 new deaths; 0.3 new deaths per 100 000; a 6% decrease).

European Region

The European Region reported over 1 million new cases and over 21 000 new deaths, an increase of 9% and decrease of 15% respectively when compared to the previous week. This represents the first rise in new cases since the week ending 10 January, and reverses declines made over the previous two reporting weeks. This week new cases rose in 36 of 61 (59%) countries and fell in 22 of 61 (36%) while new deaths rose in 16 of 61 countries (26%) and fell in 30 of 61 (49%).

The three countries reporting the highest numbers of new cases were France (149 959 new cases; 229.7 new cases per 100 000; a 14% increase), Italy (112 029 new cases; 185.3 new cases per 100 000; an 32% increase), and Czechia (82 321 new cases; 768.7 new cases per 100 000; a 26% increase). The highest numbers of deaths were reported from the Russian Federation (2829 new deaths; 1.9 new deaths per 100 000; an 11% decrease), the United Kingdom of Great Britain and Northern Ireland (2340 new deaths; 3.4 new deaths per 100 000, a 32% decrease, and Germany (2204 new deaths; 2.6 new deaths per 100 000; a 24% decrease).

South-East Asia Region

In the past week, the South-East Asia Region reported over 171 000 new cases, an increase of 9% compared to last week while the region reported over 3200 new deaths, a 47% increase[†]. Across the region half of the countries (5/10; 50%) reported increases in new cases and the other half (5/10; 50%) declined this week. New deaths rose in 3 of 10 countries (30%) and fell in 5 of 10 (50%).

The three countries reporting the highest numbers of new cases were India (105 080 new cases; 7.6 new cases per 100 000; a 21% increase), Indonesia (57 721 new cases; 21.2 new cases per 100 000; a 5% decrease) and Sri Lanka (3410 new cases; 15.9 new cases per 100 000; a 26% decrease). The three countries reporting the highest numbers of new deaths this week were Indonesia (1665 new deaths; 0.6 new deaths per 100 000; a 21% increase), India (749 new deaths; 0.1 new deaths per 100 000; a 14% increase) and Nepal (712 new deaths; 2.4 new deaths per 100 000[†]).

[†]The number of new deaths includes additional COVID-19 deaths in the past one year reported from different bodies managing COVID-19 pandemic within Nepal. The temporal distribution of these deaths is being confirmed

Western Pacific Region

The Western Pacific Region reported just over 44 000 new cases the past week, a 2% decrease compared to the previous week and reported just under 800 new deaths, a 35% decrease. Of the 22 countries in the region the number of new cases rose in 6 (27%) this week while they fell in 10 of 22 (45%). The number of new deaths increased in 1 of 22 countries (14%) and declined in 5 of 22 (23%) this week.

The three countries reporting the highest numbers of new cases in the region this week were Malaysia (18 043 new cases; 55.7 new cases per 100 000; a 2% decrease), the Philippines (14 959 new cases; 13.7 new cases per 100 000; a 24% increase) and Japan (7233 new cases; 5.7 new cases per 100 000; a 28% decrease). The three countries reporting the highest numbers of new deaths this week were Japan (443 new deaths; 0.4 new deaths per 100 000; a 12% decrease), the Philippines (221 new deaths; 0.2 new deaths per 100 000; a 61% decrease) and Malaysia (70 new deaths; 0.2 new deaths per 100 000; a 25% decrease).

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 21 February 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: WHO COVID-19 vaccine policy recommendations](#)
- [Special focus: SARS-CoV-2 variants of concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

The number of global new cases reported continues to fall for the sixth consecutive week, with 2.4 million new cases last week, a 11% decline compared to the previous week (Figure 1). The number of new deaths also continued to fall for the past three weeks, with nearly 66 000 new deaths reported last week, a 20% decline as compared to the previous week. A total of four out of six WHO regions reported declines in new cases (Table 1), with only South-East Asia and the Eastern Mediterranean regions showing a small 2% and 7% increase, respectively. The Americas continue to see the greatest drops in absolute numbers of cases. Meanwhile, the number of new deaths declined in all regions apart from the Western Pacific (6% increase).

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 21 February 2021**

**See [Annex: Data, table and figure notes](#)

In the past week, the five countries reporting the highest number of new cases continue to be the United States of America (480 467 new cases, a 29% decrease), Brazil (316 221 new cases, a 1% decrease), France (131 179 new cases, a 3% increase), the Russian Federation (92 843 new cases, an 11% decrease), and India (86 711 new cases, a 10% increase).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 21 February 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 066 990 (43%)	-19%	49 296 115 (45%)	34 386 (52%)	-23%	1 171 294 (48%)
Europe	939 271 (38%)	-7%	37 574 211 (34%)	24 102 (36%)	-19%	838 761 (34%)
South-East Asia	157 379 (6%)	2%	13 345 590 (12%)	2 189 (3%)	-6%	204 796 (8%)
Eastern Mediterranean	181 969 (7%)	7%	6 181 023 (6%)	2 443 (4%)	-3%	141 915 (6%)
Africa	66 453 (3%)	-2%	2 789 884 (3%)	2 038 (3%)	-20%	70 332 (3%)
Western Pacific	44 964 (2%)	-9%	1 576 330 (1%)	1 201 (2%)	6%	28 220 (1%)
Global	2 457 026 (100%)	-11%	110 763 898 (100%)	66 359 (100%)	-20%	2 455 331 (100%)

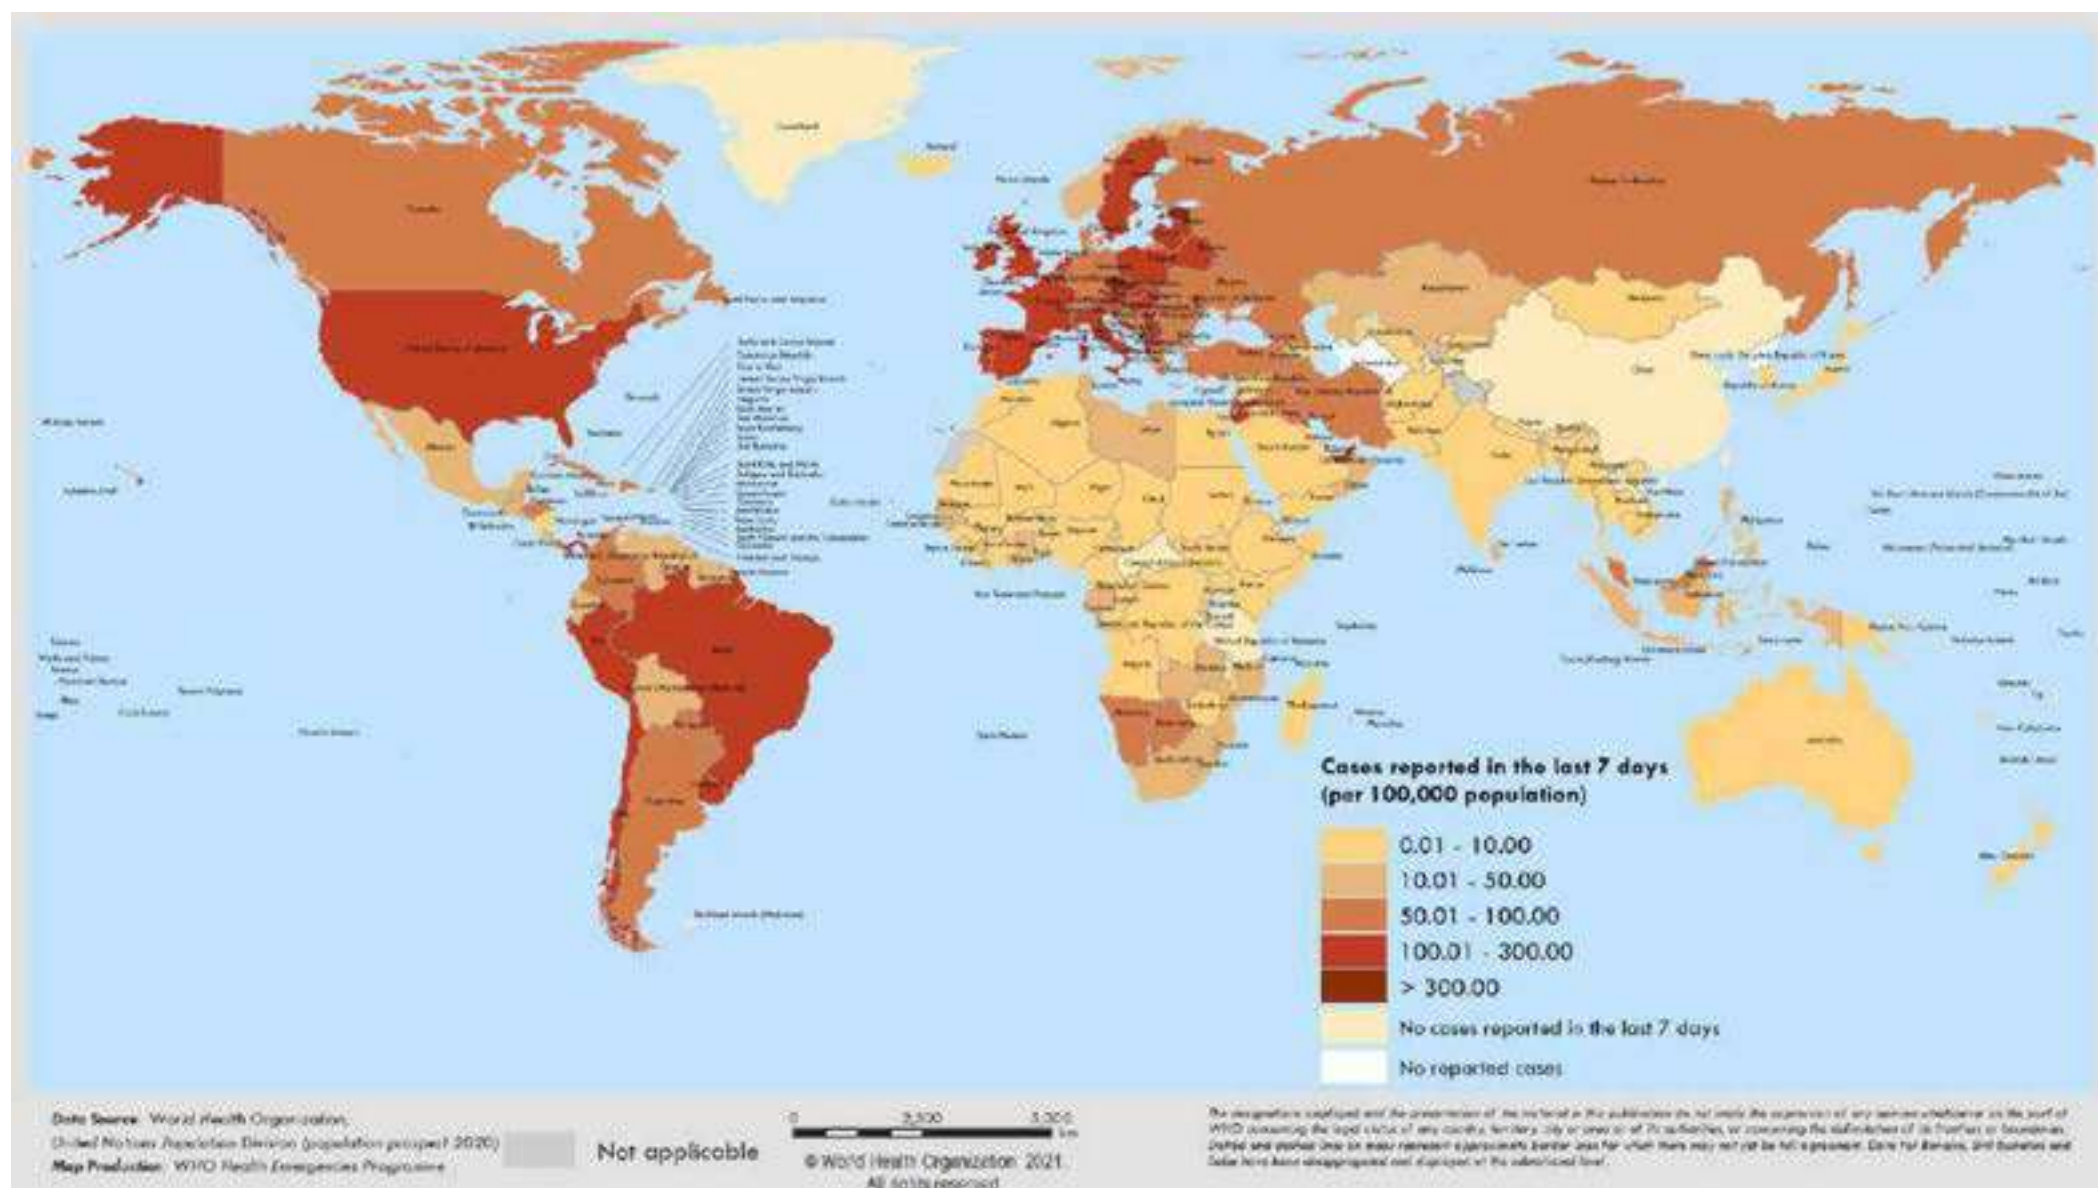

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior. Regional percentages rounded to the nearest whole number; global totals may not equal 100%.

Special Focus: WHO COVID-19 vaccine policy recommendations

WHO relies on the [Strategic Advisory Group of Experts on Immunization](#) (SAGE) to issue policy recommendations on COVID-19 vaccination to Member States. Through an established [methodological process](#) rooted in evidence-based medicine, and with the support of a dedicated COVID-19 vaccine working group, SAGE has issued three sets of interim recommendations to date, covering: the [Pfizer- BioNTech BNT162b2 vaccine](#), the [Moderna mRNA-1273 vaccine](#), and the [AstraZeneca – Oxford University AZD1222 vaccine](#).

The last of these reviews examined AstraZeneca core clinical data from the Phase 1-3 clinical trials. The WHO interim recommendations that ensued apply to AZD1222 (named generically as ChAdOx1-S [recombinant]) vaccine against COVID-19, developed by Oxford University (United Kingdom) and AstraZeneca, as well as to ChAdOx1-S [recombinant]) vaccines against COVID-19 produced by other manufacturers. These include the Serum Institute of India and SK Bioscience (South Korea), both of which rely on the AstraZeneca core clinical data and have demonstrated equivalence in their regulatory review. It will be the responsibility of regulatory bodies and WHO's [Emergency Use Listing](#) (EUL) process to ensure that products emerging from different manufacturing facilities are equivalent.

For each of these three vaccines, SAGE was able to issue policy recommendations because of the publication of appropriate data by the vaccine developers and on the basis that the vaccine was in the process of acquiring EUL from WHO or a marketing authorization from a stringent regulatory authority, such as the European Medicines Agency. WHO assesses vaccines with a pathway to prequalification or EUL as they become available. In that context and under exceptional circumstances, WHO will review products with authorization from a regulatory authority considered by WHO as maintaining the highest of standards, even if EUL has yet to be confirmed, such as was the case for the Moderna and AstraZeneca vaccines. It should further be noted that EUL is a WHO time-limited regulatory recommendation based on a risk-benefit assessment of limited amount of quality, safety and efficacy data for use during a public health emergency. SAGE recommendations, on the other hand, are policy recommendations to guide ministries of health and their recommending bodies and disease programmes on the use of regulated products to optimize the individual and public health benefit of vaccines. The two sets of recommendations are complementary. WHO cannot comment or make recommendations on vaccines until the manufacturer in question has chosen to share the relevant data and allows SAGE, on behalf of WHO, to conduct a formal assessment. WHO urges all manufacturers to share evidence to allow prompt review and guidance by designated WHO experts and advisory groups.

SAGE does not usually make vaccine- or product-specific recommendations, issuing instead one recommendation that covers all vaccines for a given disease, unless the evidence suggests product-specific recommendations are needed. The current situation with respect to COVID-19 differs as a large variety of vaccines based on very different platform technologies is being developed, and data on the performance of each vaccine are still emerging. Products also have varying characteristics, including storage and handling requirements, such that some may be considered more suitable for certain settings than others. Consequently, SAGE is issuing product-specific recommendations for COVID-19 and will likely continue doing so for additional candidate vaccines. In the longer run, these recommendations may be regrouped into overall recommendations for COVID-19 vaccination.

SAGE began to mobilize its evidence review and recommendation process for COVID-19 vaccination policy as early as the summer of 2020. An essential starting point to this process was the preparation and release of two critical documents forming the foundation for future vaccine-specific interim recommendations. These consist of the [WHO SAGE values framework for the allocation and prioritization of COVID-19 vaccination](#) and the [WHO SAGE Roadmap for Prioritizing Uses of COVID-19 Vaccines in the Context of Limited Supply](#), which jointly guide countries in their prioritization of target groups. The Roadmap highlights the importance of vaccinating

frontline health workers and older people with and without comorbidities first, and outlines how additional groups can then be vaccinated as more vaccine becomes available, in keeping with the local epidemiological context. The Roadmap also encourages national programmes to consider groups that are disproportionately affected by the pandemic and to continuously base vaccination decisions on a thorough risk benefit assessment.

For all three vaccines reviewed to date, SAGE concluded that the known and potential benefits outweigh the known and potential risks. The high efficacy of each of the products was acknowledged, despite insufficient data on if and how these vaccines impact virus transmission, although it is likely there will be some level of protection against transmission. These vaccines will have a beneficial effect on the high rate of severe disease and mortality caused by SARS-CoV-2 infection, a key objective of vaccination. More work is needed to understand if this is the case for all circulating variants of concern.

Based on current data for each of these three vaccines, a regimen of 2 full doses of the same vaccine is recommended, injected intramuscularly in the upper arm. This means the dosage cannot be reduced, or interchanged (i.e., if the first dose is Pfizer-BioNTech vaccine, the second should not be Moderna or AstraZeneca vaccines). There are multiple reasons for this, including a lack of research so far on interchangeability. Furthermore, each vaccine has a different minimum interval time between doses: a second dose of the Pfizer-BioNTech vaccine can be administered after three weeks; the Moderna vaccine requires a minimum interval of four weeks, which can be extended to six weeks; and the AstraZeneca vaccine requires an interval of no less than eight weeks which can be extended to twelve. This latter WHO recommendation deviates slightly from the vaccine developers, who have determined the product is sufficiently efficacious when a second dose is administered after four weeks. SAGE preferred to recommend a longer interval for the AstraZeneca vaccines based on the evidence that supported an improved vaccine performance (for efficacy and immunogenicity) when delaying the second dose by a few weeks.

With all three vaccines, it is recommended that the administration of any other vaccines against other conditions be held off for at least two weeks after vaccination against COVID-19, until data on co-administration become available.

The minimum recommended ages for COVID-19 vaccination vary only slightly between the three vaccines and SAGE confirmed there is no upper limits for any of the three vaccines. These conclusions were based on available data and will evolve when more efficacy and safety data become available. The same evidence scenario applies for specific populations such as pregnant or lactating women, as well as persons with compromised immune systems or living with HIV. For each of these groups, there is no reason to believe the vaccine would be harmful – especially since these are not vaccines containing live viruses which can replicate; however, more evidence is being sought in order to further inform WHO policy recommendations. Whenever possible, potential vaccine recipients should be informed and counselled in relation to the available data and a risk-benefit assessment of their individual case. It should be clarified that, while recommendations exist for these profiles, there are no current COVID-19 vaccination recommendations for children and adolescents.

WHO recommendations on who may be vaccinated with each of the three vaccines are summarized in Table 2, with the assumption that people falling into high-risk groups (e.g., health workers or people with co-morbidities) are being prioritized as per the WHO SAGE Roadmap on COVID-19 vaccines.

Table 2. Who can be vaccinated with which vaccine against COVID-19?

SAGE INTERIM RECOMMENDATION	Pfizer-BioNTech BNT162b2 vaccine	Moderna mRNA-1273 vaccine	Oxford University – Astra Zeneca AZD1222 vaccine
Minimum age requirement	16 years 	18 years 	18 years 
Maximum age requirement	none 	none 	none 
Ok for pregnant women?	Yes , if in high priority group and ok'd by health care provider. 	Yes , if in high priority group and ok'd by health care provider. 	Yes , if in high priority group and ok'd by health care provider. 
Ok for breastfeeding mothers?	Yes , if in high priority group. 	Yes , if in high priority group. 	Yes , if in high priority group. 
Ok for people with compromised immune systems?	yes 	yes 	yes 
Ok for people living with HIV?	yes 	yes 	yes 
Ok for people previously infected with SARS-CoV-2 (confirmed by PCR test)?	Yes , though that person may elect to delay vaccination up to 6 months from the time of infection. 	Yes , though that person may elect to delay vaccination up to 6 months from the time of infection. 	Yes , though that person may elect to delay vaccination up to 6 months from the time of infection. 
Ok for people with a history of severe allergic reaction (anaphylaxis)?	no 	no 	No , if anaphylactic reaction was linked to any component of the vaccine. 

No studies have yet been conducted to compare these three vaccines and despite the above listed similarities, there are also notable differences such as the dose size, the number of doses per container, and the required storage conditions. These differences affect the practices around vaccination, including the handling of vaccine vials and the timeframe within which a vial must be used once thawed or brought to ambient temperatures. In some cases, the less constraining temperature requirements can make storage and distribution much easier, especially when freezing is neither needed nor recommended. However, in no way do these differences diminish the respective performance of the vaccines, which in all three cases are recognized as highly efficacious and with excellent safety profiles.

While these vaccines, and others coming through the pipeline, offer us reason to be optimistic, the current lack of evidence of their effect on transmission, circulating variants of concern, coupled with a continuing limited supply of the vaccines, mean that more data collection is required, and public health and social measures (PHSM) must continue, and should be practised by all individuals regardless of vaccination status, including use of face masks, physical distancing, hand-washing and other measures.

Special Focus: Update on SARS-CoV-2 Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available.

Further information on the background of the variants of concern (VOCs) is available from previously published [Disease Outbreak News](#) and recent publications of the [Weekly Epidemiological Update](#). Here we provide an update on ongoing studies and the geographical distribution of select VOCs as reported by countries, territories and areas (hereafter countries) as of 23 February 2021. New variants of potential interest or concern are continuously emerging; we provide here an update on two such variants currently under review.

Results of ongoing studies of VOCs are summarized in Table 3 below. While many countries worldwide are currently experiencing a decline in overall SARS-CoV-2 infections likely as a result of the public health and social measures (PHSM) implemented, there has been an increased number of reports of variants which are of concern. As surveillance activities at local and national levels are strengthened, including strategic genomic sequencing to detect cases infected with SARS-CoV-2 variants, the number of countries reporting VOCs has continued to increase in the past two weeks (Table 3, Figures 3, 4 and 5, Annex 2). In addition, the number of countries reporting local transmission of VOCs has increased in the same period.

Increased transmissibility has been reported for some VOCs resulting in increased incidence in settings experiencing community transmission. PHSM remain critically important to curb the spread of SARS-CoV-2, including newly reported variants. Evidence from multiple countries with extensive transmission of VOCs has indicated that the implementation of physical distancing and other PHSM has been effective in reducing COVID-19 case incidence, which has led to a reduction in hospitalizations among COVID-19 patients. Findings from new studies evaluating transmission, severity and impact on medical countermeasures will continue to help inform PHSM employed by Member States.

Table 3: Overview of emerging information on key variants of concern, as of 23 February 2021*

Nextstrain clade	20I/501Y.V1	20H/501Y.V2 [†]	20J/501Y.V3
Pango lineage	B.1.1.7	B.1.351	B.1.1.28.1
GISAID clade	GR	GH	GR
Alternate names	VOC 202012/01 [†]	VOC 202012/02	P.1 [†]
First detected by	United Kingdom	South Africa	Brazil / Japan
First appearance	20 September 2020	Early August 2020	December 2020
Key spike mutations	H69/V70 deletion; Y144 deletion; N501Y; A570D; D614G; and P681H	L242/A243/L244 deletion; N501Y; D614G; E484K; and K417N	N501Y; D614G; E484K; and K417N
Key mutation in common	S106/G107/F108 deletion in Non-Structural Protein 6 (NSP6)		
Transmissibility*	Increased ¹ (36%-75%) ² , increased secondary attack rate ³ (10% to 13%)	Increased [1.50 (95% CI: 1.20-2.13) times more transmissible than previously circulating variants] ^{4,5}	Suggested to be increased
Severity*	Possible increased severity and mortality ⁶	No impact reported to date ^{4,5} , no significant change in-hospital mortality ⁷	Under investigation, no impact reported to date
Neutralization capacity*	Slight reduction but overall neutralizing titers still remained above the levels expected to confer protection ⁸	Decreased, suggesting potential increased risk of reinfection ^{4,9,10}	Potential decrease, small number of reinfections reported ^{11,12}
Potential impacts on vaccines*	No significant impact on Moderna, Pfizer-BioNTech, and Oxford-AstraZeneca vaccines ¹³⁻¹⁶	Moderna and Pfizer-BioNTech: Reduction in the neutralizing activity, but impact on protection against disease not known. ¹³⁻¹⁶ Novavax and Johnson & Johnson: Lower vaccine efficacy in South Africa compared to settings without the variant (press release data only). Moderate-severe disease were assessed. Serologic neutralization results pending. ^{17,18} Oxford/AstraZeneca: Limited vaccine efficacy against mild-moderate COVID-19 disease, with wide confidence intervals, impact on severe disease undetermined. Serologic neutralization substantially reduced compared with original strains, based on small number of samples analyzed ^{19,20}	Under investigation
Potential impacts on diagnostics*	S gene target failure (SGTF). ¹⁹ No impact on Ag RDTs observed ²¹	None reported to date	None reported to date
Countries reporting cases (newly reported in last week)**	101 (7)	51 (5)	29 (8)

[†]While work is ongoing to establish standardized nomenclature for key variants, these are the names by which WHO will refer to them in this publication.

*Generalized findings as compared to non-VOC viruses. Based on emerging evidence from multiple countries, including non-peer-reviewed preprint articles and reports from public health authorities and researchers – all subject to ongoing investigation and continuous revision.

**Includes official and unofficial reports of VOCs detections in countries among either travellers (imported cases only) or community samples (local transmission).

Variant VOC 202012/01

Since our last update on 16 February, VOC 202012/01 has been detected in seven additional countries. As of 23 February, a total of 101 countries across all six WHO regions have reported cases of this variant (Figure 3). Community transmission has been reported in at least 45 countries across five WHO regions, noting that transmission classification is currently incomplete for 23 (23%) countries reporting this variant.

Since January 2021, several countries and in the European Region in particular, have observed a marked increase in the number and proportion of cases infected with VOC 202012/01 among samples tested by PCR-based screening and whole genome sequencing.²² As of 8 February, the proportion of sequenced samples in which VOC 202012/01 was detected in Spain varied across the different regions from 0.4% to 53.3%.²³ During the epidemiological week 6 (from 7 to 14 February 2021), Germany detected VOC 202012/01 in 22% of the specimens analysed (23 000 samples tested),²⁴ 36% in France,²⁵ and 47% in Denmark.^{26,27} In the United States of America (USA), genomic sequencing by one commercial laboratory suggested prevalence of VOC 202012/01 to be approximately 1% nationwide, and over 2% in some States as of 3 February 2021.²⁸ Another study estimated a 3.6% prevalence of VOC 202012/01 by the end of January 2021 using the S-gene target failure (SGTF; a proxy used to identify cases infected with VOC 202012/01).²⁹ As of 21 February, the USA has reported a total of 1661 cases from 44 States in the United States of America.³⁰ Additionally, the VOC 202012/01 has increasingly been associated with outbreaks in several different settings.^{31,32}

On 21 January 2021, the United Kingdom's New and Emerging Respiratory Virus Threats Advisory Group (NERVTAG) released analyses suggesting increased disease severity and risk of death in cases with SGTF compared to cases without SGTF.³ When comparing cases with SGTF to cases without SGTF: (i) one study reported the relative hazard of death within 28 days of testing to be 1.35 (95% CI: 1.08-1.68); (ii) one study reported the mean case fatality ratio to be 1.36 (95% CI 1.18-1.56) by a case-control weighing method; (iii) one study reported a mortality hazard ratio of 1.91 (95% CI 1.35-2.71) (studies unpublished to date). In addition, a matched cohort analysis reported a death risk ratio of 1.65 (95% CI: 1.21-2.25) for cases infected with VOC 202012/01 compared with non-VOC 202012/01 cases. Although there are limitations to these studies including representativeness of the dataset used, these findings follow an initial assessment that there was no significant difference in the risk of hospitalization or death as compared to other variants, conducted in December 2020. The absolute risk of death of SARS-CoV-2 remains low, and additional studies are required to investigate these findings.

Based on available information, VOC 202012/01 has not been associated with decreased neutralization activity of polyclonal antibodies such as vaccine-derived or convalescent sera. However, the genomic changes of the epitope which binds to the host cell receptor, such as deletions in the N terminal domain, may affect binding of this variant to monoclonal antibodies, indicating possible effects on the efficacy of monoclonal antibodies used as therapeutics.³³

A pre-print study with a small sample size (n=65, including 7 infected individuals with VOC 202012/01), suggested that individuals infected with VOC 202012/01 had longer duration of acute infection and similar peak viral load when compared to non-VOC 202012/01 variants.³⁴ However, these are preliminary findings and require further investigations with larger cohorts.

Figure 3. Countries, territories and areas reporting SARS-CoV-2 VOC 202012/01 as of 23 February 2021

Variant 501Y.V2

Since the last update on 16 February, 501Y.V2 has been reported from five additional countries – now totalling 51 countries across all six WHO regions (Figure 4). Community transmission of 501Y.V2 has been reported in 13 countries across four WHO regions, noting the transmission classification is currently incomplete for 21 (41%) countries reporting this variant. In several areas within the African Region, variant 501Y.V2 has been reported to comprise a high proportion of sequenced samples.³⁵

Studies highlighting reductions in neutralizing antibody activity against 501Y.V2 following either natural infection or vaccination, with potential to impact re-infection risk or vaccine effectiveness have been discussed previously (see Table 3, and past editions of the [Weekly Epidemiological Update](#)). A preliminary report with a small sample size (n=20) indicated that the serum neutralization capacity of serum elicited by BNT162b2 vaccine, produced by Pfizer-BioNTech, was weaker against variant 501Y.V2 by approximately two thirds as compared to that of another variant.³⁶ Further studies are needed to fully understand efficacy of existing vaccines.

Recent preliminary evidence suggests that variant 501Y.V2 may compromise immunity indicating potential increased risk of reinfection. There is now growing evidence that the mutations present in this variant may help the virus evade immune system responses triggered by previous infections of SARS-CoV-2 or by vaccines. There has been a report of a SARS-CoV-2 reinfection with the 501Y.V2 variant months after recovering from a first episode of COVID-19 with a more severe clinical presentation.³⁷

Figure 4. Countries, territories and areas reporting SARS-CoV-2 501Y.V2 as of 23 February 2021

Variant P.1

Since our last update, variant P.1 has been reported in eight additional countries. To date, this variant is reported in 28 countries across all six WHO regions (Figure 5). Community transmission of P.1 has been reported in at least three countries in one WHO region, noting the transmission classification is currently incomplete for 8 (28%) countries reporting this variant.

In a genomic survey conducted from April to November 2020 in Amazonas State, Brazil, variant P.1 was found to be the most prevalent variant among 148 whole-genomes sequenced, comprising 47% (69/148) of specimens collected from 12 municipalities.³⁸ During the period of 1 November 2020 to 13 January 2021, sequencing of samples from different municipalities in Amazonas found rapid increase in the proportion of variant P.1 in the state. In the state capital Manaus, cases associated to the P.1 variant were initially detected on the 4 December 2020 and as of January 2021, 91% of cases were infected with the P1 variant. Furthermore, the variant was found in a widespread geographic distribution in the state.³⁹

Figure 5. Countries, territories and areas reporting SARS-CoV-2 P.1 variant as of 23 February 2021

Emerging variants of interest or concern

To inform local, national and regional risk assessments, surveillance of SARS-CoV-2 variants continues globally with timely sharing of sequence data. As of 23 February 2021, over 590 000 sequences of SARS-CoV-2 globally have been uploaded into publicly available databases. New variants of potential interest or concern are continuously emerging and undergo assessment. We provide here an update on two such variants currently under review.

Variant B.1.525 (also referred to as VUI-202102/03, and previously UK1188), was first detected in the United Kingdom and Nigeria in December 2020.⁴⁰ Since then, it has been detected in at least another 13 countries.⁴¹ This variant is partially similar to the 501Y.V2 variant and contains mutations which may be associated with some degree of biological significance, including the E484K, Q677H and F888L mutations, as well as a similar number of deletions that are contained in B.1.1.7.

A variant of B.1.1.7 with an E484K mutation (labelled VOC 202102/02 by the United Kingdom health authorities) has been detected in South West England. As of 17 February 2021, 26 cases of this variant have been detected in the United Kingdom.³³ Local authorities are responding with enhanced PHSM with the aim to prevent further spread. The E484K mutation is a mutation in the spike protein and has been associated with antigenic change, as well as increased binding affinity to the human host receptor, Angiotensin Converting Enzyme 2 (ACE2), in conjunction with the N501Y mutation.⁴² E484K has been labelled as an escape mutation, so called because it may help the SARS-CoV-2 virus to evade host immune defences. It has been identified as an adaptation of SARS-CoV-2 in at least one immunocompromised patient with long lasting infection.⁴³ The E484K mutation has been identified independently in several variants (including 501Y.V2 and P.1.), indicating convergent mutations, where distinct lineages independently acquire similar genetic mutations.^{42,44} Although there is no evidence that this mutation alone is associated with increased disease severity or higher transmissibility, E484K is of significance due to its possible impact on immune response, vaccine efficacy and transmissibility.⁴⁰

Further investigations are required to better understand the importance of specific mutations (and/or clusters of mutations), whether they are identified in emerging variants of interest or concern, as well as ongoing adaptations and evolution of SARS-CoV-2.

WHO Recommendations

National and local authorities are encouraged to continue strengthening existing disease control activities, including epidemiological surveillance, strategic testing, and increased routine systematic sequencing of SARS-CoV-2 where feasible (for more information, please see WHO advice in the previously published [Disease Outbreak News](#)).

WHO has been tracking mutations since the beginning of the pandemic. In June 2020, WHO established the SARS-CoV-2 Virus Evolution Working Group (VEWG) to specifically assess new variants. Together with Member States and partners, a global risk monitoring framework has been established to:

- Coordinate and harmonize a global system for monitoring and assessing SARS-CoV-2 variants and their impact;
- Identify critical priorities, thresholds, and triggers for decision-making;
- Define a multi-disciplinary coordination mechanism to collect, analyze, and share data to inform decision-making, including on vaccination programs; and
- Leverage and enhance existing technical networks and expert groups.

Working definitions of SARS-CoV-2 variants of interest and variants of concern have been developed and are currently under review, with an aim to publish later this week.

WHO is working to increase sequencing capacities globally and has published [a comprehensive implementation guide and risk-monitoring framework](#) to support countries set up high-impact sequencing programmes for SARS-CoV-2 variants and maximize public health impact.

PHSM have proven to remain effective against VOCs to date. WHO continues to advise that the application and adjustment of PHSM should be driven by detailed data analyses of epidemiology at the most local level possible (for more information, please see our [technical guidance](#)).

WHO regional overviews

African Region

In the past week, the African Region reported over 66 400 cases and 2000 deaths, a 2% and 20% decrease respectively compared to the previous week. This is the fifth consecutive week the Region reported decreases in both new cases and deaths. The highest numbers of new cases were reported in South Africa (12 304 new cases; 20.7 new cases per 100 000 population; a 25% decrease), Mozambique (6380 new cases; 20.4 new cases per 100 000; a 42% increase) and Ethiopia (6153 new cases; 5.4 new cases per 100 000; a 45% increase).

The countries reporting the highest number of new deaths in the past week were South Africa (1119 new deaths; 1.9 new deaths per 100 000; a 32% decrease), Ethiopia (90 new deaths; 0.1 new deaths per 100 000; a 150% increase), and Nigeria (84 new deaths; <0.1 new deaths per 100 000; a 16% decrease).

Region of the Americas

Over 1 million new cases and over 34 300 new deaths were reported in the Region of the Americas this week, a 19% and 23% decrease respectively compared to the previous week. The highest numbers of new cases were reported from the United States of America (480 467 new cases; 145.2 new cases per 100 000 population; a 29% decrease), Brazil (316 221 new cases; 148.8 new cases per 100 000; a 1% decrease) and Mexico (51 537 new cases; 40 new cases per 100 000; a 22% decrease).

The highest numbers of new deaths were reported from the same countries, the United States of America (14 747 new deaths; 4.5 new deaths per 100 000; a 31% decrease), Brazil (7276 new deaths; 3.4 new deaths per 100 000; a 2% decrease) and Mexico (6408 new deaths; 5.0 new deaths per 100 000; a 22% decrease).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 181 000 new cases, a 7% increase compared to last week. The region reported just over 2400 new deaths, a 3% decrease. The three countries reporting the highest numbers of new cases this week were the Islamic Republic of Iran (55 208 new cases; 65.7 new cases per 100 000 population; a 7% increase), Iraq (23 122 new cases; 57.5 new cases per 100 000; a 63% increase) and the United Arab Emirates (22 570 new cases; 228.2 new cases per 100 000; a 2% increase).

The highest numbers of new deaths this week have been reported in the Islamic Republic of Iran (526 new deaths; 0.6 new deaths per 100 000 population; a 12% increase), Egypt (363 new deaths; 0.4 new deaths per 100 000; a 10% increase) and Lebanon (336 new deaths; 4.9 new deaths per 100 000; a 16% decrease).

European Region

The European Region reported over 939 000 new cases and over 24 000 new deaths, a decrease of 7% and 19% respectively when compared to the previous week. The three countries reporting the highest numbers of new cases were France (131 179 new cases; 201 new cases per 100 000; a 3% increase), the Russian Federation (92 843 new cases; 63.6 new cases per 100 000; an 11% decrease), and Italy (84 977 new cases; 140.5 new cases per 100 000; an 1% decrease).

The highest numbers of deaths were reported from the United Kingdom (3457 new deaths; 5.1 new deaths per 100 000; a 28% decrease), the Russian Federation (3167 new deaths; 2.2 new deaths per 100 000; a 9% decrease) and Germany (2881 new deaths; 3.4 new deaths per 100 000; a 16% decrease).

South-East Asia Region

In the past week, the South-East Asia Region reported over 157 000 new cases, an increase of 2% compared to last week. The region reported over 2100 new deaths, a 6% decrease. The three countries reporting the highest numbers of new cases were India (86 711 new cases; 6.3 new cases per 100 000; a 10% increase), Indonesia (60 650 new cases; 22.2 new cases per 100 000; a 5% decrease), and Sri Lanka (4628 new cases; 21.6 new cases per 100 000; a 26% decrease).

The three countries reporting the highest numbers of new deaths this week were Indonesia (1380 new deaths; 0.5 new deaths per 100 000; an 11% decrease), India (660 new deaths; <0.1 new deaths per 100 000; a 2% increase) and Bangladesh (76 new deaths; <0.1 new deaths per 100 000, no change in new deaths reported this week as compared to last week).

Western Pacific Region

The Western Pacific Region reported just under 45 000 new cases the past week, a 9% decrease compared to the previous week. The region reported 1200 new deaths, a 6% increase. The three countries reporting the highest numbers of new cases in the region this week were Malaysia (18 467 new cases; 57.1 new cases per 100 000; a 20% decrease), the Philippines (12 033 new cases; 11.0 new cases per 100 000; a 2% increase), and Japan (10 035 new cases; 7.9 new cases per 100 000; a 9% decrease).

The three countries reporting the highest numbers of new deaths this week were the Philippines (561 new deaths; 0.5 new deaths per 100 000; a 41% increase), Japan (505 new deaths; 0.4 new deaths per 100 000; a 12% decrease), and Malaysia (93 new deaths; 0.3 new deaths per 100 000; an 8% decrease).

Key weekly updates

- **WHO Director-General Dr Tedros issued a [statement](#) on Tanzania on 20 February** “A number of Tanzanians travelling to neighbouring countries and beyond have tested positive for COVID-19.” The situation in Tanzania remains concerning. WHO urges Tanzania:
 - to start reporting COVID-19 cases and share data;
 - to implement the public health measures that we know work in breaking the chains of transmission;
 - and to prepare for vaccination.

GISRS Surveillance of SARS-CoV-2

****See [Annex : Data, table and figure notes](#)**

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 14 February 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: Global Influenza Surveillance and Response System](#)
- [Special focus: SARS-CoV-2 variants of concern](#)
- [WHO regional overviews](#)
- [Key weekly updates](#)

Global overview

The number of global new cases reported has continued to fall, with 2.7 million new cases last week, a 16% decline over 500 000 fewer new cases compared to the previous week (Figure 1). The number of new deaths reported also fell, with 81 000 new deaths reported last week, a 10% decline as compared to the previous week. A total of five out of six WHO regions reported a double-digit percentage decline in new cases (Table 1), with only the Eastern Mediterranean Region showing a 7% rise. Europe and the Americas continue to see the greatest drops in absolute numbers of cases. Meanwhile, the number of new deaths declined in all regions.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 14 February 2021**

**See [Annex: Data, table and figure notes](#)

In the past week, the five countries reporting the highest number of new cases continue to be the United States of America (673 630 cases, a 23% decrease), Brazil (318 290 cases, a 3% decrease), France (127 565 cases, a 6% decrease), the Russian Federation (104 602 cases, an 11% decrease), and the United Kingdom of Great Britain and Northern Ireland (97 271 cases, a 27% decrease).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 14 February 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 315 480 (48%)	-16%	48 228 712 (45%)	44 385 (55%)	-2%	1 136 906 (48%)
Europe	968 943 (36%)	-18%	36 575 529 (34%)	28 404 (35%)	-19%	812 410 (34%)
South-East Asia	154 414 (6%)	-13%	13 188 211 (12%)	2 340 (3%)	-9%	202 607 (8%)
Eastern Mediterranean	170 445 (6%)	7%	5 998 998 (6%)	2 519 (3%)	-9%	139 468 (6%)
Africa	68 115 (2%)	-20%	2 723 431 (3%)	2 558 (3%)	-21%	68 294 (3%)
Western Pacific	49 577 (2%)	-20%	1 531 366 (1%)	1 134 (1%)	-13%	27 019 (1%)
Global	2 726 974 (100%)	-16%	108 246 992 (100%)	81 340 (100%)	-10%	2 386 717 (100%)

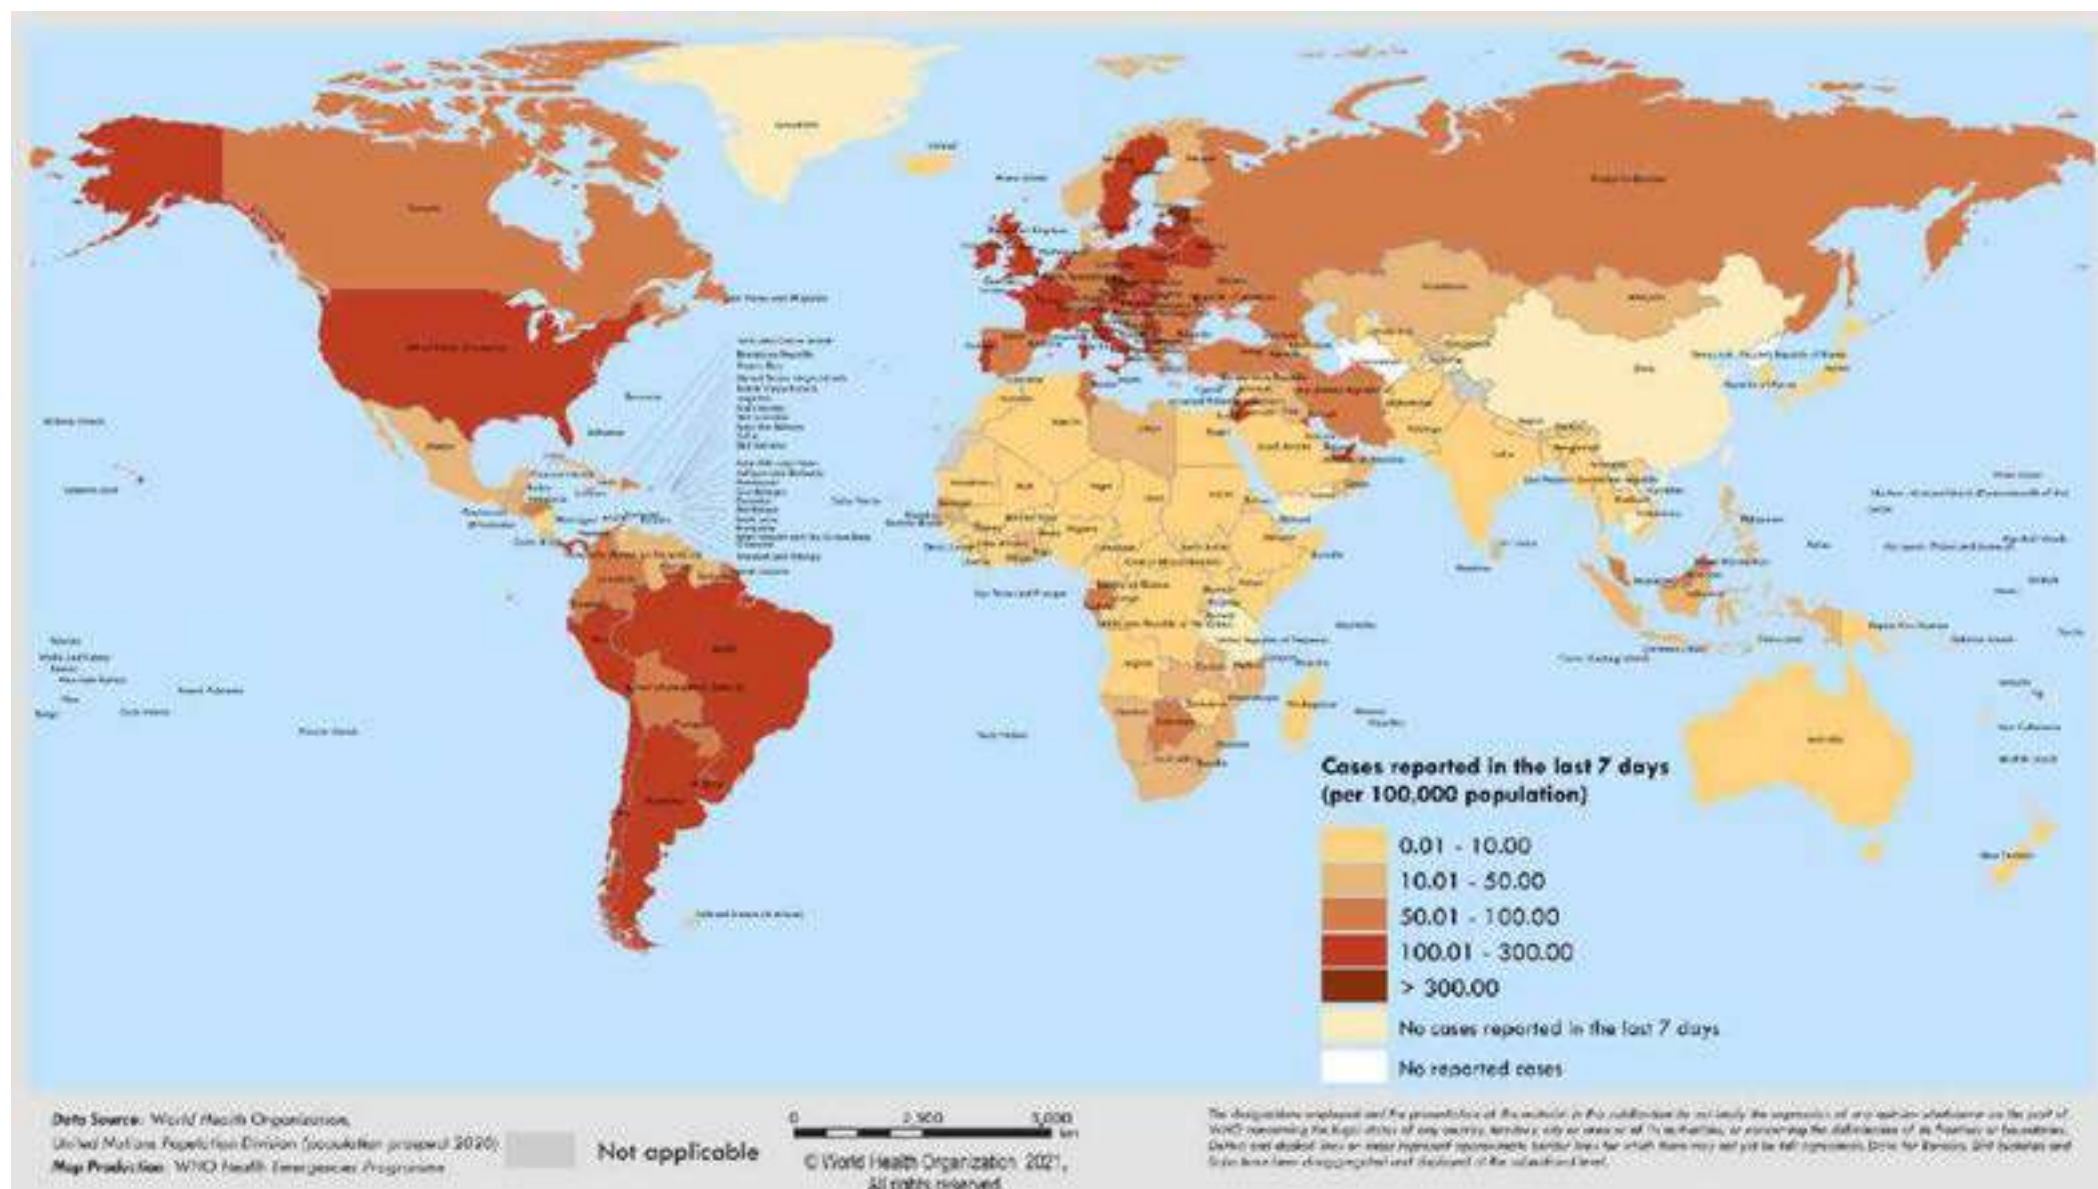

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior. Regional percentages rounded to the nearest whole number, global totals may not equal 100%.

**See [Annex: Data, table and figure notes](#)

**See [Annex: Data, table and figure notes](#)

Special Focus: Global Influenza Surveillance and Response System – leveraging influenza sentinel surveillance systems to respond to COVID-19

Overview

The [Global Influenza Surveillance and Response System](#) (GISRS) is a network of 158 institutions monitoring the spread and evolution of influenza all year-round. It includes six WHO Collaborating Centres and National Influenza centres (NICs) from 126 countries, areas and territories. It functions as a global mechanism for surveillance, preparedness and response for seasonal, pandemic and zoonotic influenza, and a global alert for novel influenza viruses and other respiratory pathogens. More than 3.5 million respiratory specimens are tested for influenza each year with [assured quality and standards](#). These specimens are collected from patients presenting at sentinel hospitals and primary care settings with influenza-like illness (ILI) and severe acute respiratory infection (SARI). More than 10 000 representative influenza viruses are sequenced each year and the genetic sequence data shared via the [Global Initiative on Sharing Avian Influenza Data](#) (GISAID). Countries also typically share about 40 000 influenza specimens throughout the year with WHO Collaborating Centres, of which around a quarter undergo a detailed virus characterization that informs the biannual [recommendations](#) for the seasonal influenza vaccine composition for the northern and southern hemispheres.

GISRS and COVID-19

Throughout the COVID-19 response, GISRS laboratories have contributed significantly to country diagnostic and sequencing capacities. Since the onset of the pandemic, [87% of GISRS laboratories have been serving as national reference laboratories for SARS-CoV-2 detection](#). GISRS has leveraged its [External Quality Assessment Program](#) (EQAP) for influenza molecular diagnostics to develop and implement the SARS-CoV-2 EQAP to more than 233 national public health laboratories (including 130 NICs) from 164 countries, areas and territories, with 94% of the laboratories demonstrating 100% correct results.

Early in the COVID-19 pandemic, influenza surveillance systems were leveraged to address the critical need to monitor trends in community circulation of SARS-CoV-2 and influenza. To date, approximately 60 countries have reported integrated SARS-CoV-2 and influenza data that complement SARS-CoV-2 cases detected through non-sentinel sources. The transmission trends based on sentinel surveillance serve to complement and corroborate the transmission trends seen from non-sentinel data sources.

The emergence of SARS-CoV-2 Variants of Concern highlights the importance of quality, representativeness and geographical coverage of genetic sequencing, and the timeliness of sharing of genetic sequence data on publicly accessible databases. As of 10 February 2021, more than 450 000 whole genome sequences of SARS-CoV-2 from 131 countries had been shared with GISAID. However, the majority (approximately 70%) are from three countries (Denmark, the United Kingdom and the United States of America). At least 60% of GISRS laboratories have shared whole genome sequences with GISAID (Figure 3).

The [IHR Emergency Committee for COVID-19](#) recommended further increases in global sequencing capacities and encouraged the further rapid sharing of data. It recognizes the role of GISRS to strengthen sequencing capacities for SARS-CoV-2 and increase the global genetic database that improves the geographic and demographic representativeness, timeliness and quality of meta-data around the world. WHO is working with GISRS to expedite the sequencing component of sentinel surveillance for SARS-CoV-2 along with influenza and has [issued guidance](#) to support in this effort.

Figure 3: SARS-CoV-2 detection and sequencing capacities and capabilities

Special Focus: Update on SARS-CoV-2 Variants of Concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available. Further information on the background of the variants of concern (VOC) is available from previously published [Disease Outbreak News](#) and recent publications of the [Weekly Epidemiological Update](#). Here we provide an update on the geographical distribution of three variants of concern as reported by countries, territories and areas (hereafter countries) as of 15 February 2021. New variants of potential interest or concern are currently under review and may be incorporated into future updates.

Table 2: Condensed overview of emerging information on key variants of concern, as of 15 February 2021*

Nextstrain clade	20I/501Y.V1	20H/501Y.V2 [†]	20J/501Y.V3

First detected by	United Kingdom	South Africa	Brazil / Japan
First appearance	20 September 2020	Early August 2020	December 2020
Key spike mutations	<ul style="list-style-type: none"> • H69/V70 deletion • Y144 deletion • N501Y • A570D • D614G • P681H 	<ul style="list-style-type: none"> • L242/A243/L244 deletion • N501Y • D614G • E484K • K417N 	<ul style="list-style-type: none"> • N501Y • D614G • E484K • K417N
Key mutation common to all 3 variants	S106/G107/F108 deletion in Non-Structural Protein 6 (NSP6)		
Countries reporting cases (newly reported in last week)**	94 (8)	46 (2)	21 (6)

* A more detailed version of this table is available in the [previous Weekly Epidemiological Update](#), and an update version will be available in the next issue.

[†] While work is ongoing to establish standardized nomenclature for key variants, these are the names by which WHO will refer to them in this publication.

** Includes official and unofficial reports of VOCs detections in countries among either travellers (imported cases only) or community samples (local transmission).

Variant VOC 202012/01

Since our last update on 9 February, variant VOC 202012/01 has been detected in eight additional countries. As of 16 February, a total of 94 countries across all six WHO regions have reported either imported cases or community transmission of this variant (Figure 4). Local transmission has been reported in at least 47 countries across all six WHO regions.

In an updated report on SARS-CoV-2 and increased circulation of variants of concern in the EU/EEA and vaccine rollout, the European Centre for Disease Control and Prevention (ECDC) highlights that while a number of European countries have been reporting an overall decrease in the incidence of COVID-19, likely due to a strong combination of public health and social measures, the majority of countries in Europe continues to experience high or increasing notification rates among older age groups and/or high death rates.¹ Moreover, among samples tested in Europe by PCR-based screening and whole genome sequencing, the proportion of cases infected with VOC 202012/01 has increased in the past weeks, indicating community transmission in a number of countries.¹

¹ European Centre for Disease Prevention and Control, Risk assessment on COVID-19, 15 February 2021. Available at : <https://www.ecdc.europa.eu/en/current-risk-assessment-novel-coronavirus-situation>

Figure 5. Countries, territories and areas reporting SARS-CoV-2 variant VOC 202012/01 as of 16 February 2021

Variant 501Y.V2

Since the last update on 9 February, 501Y.V2 has been reported from two additional countries— now totaling 46 countries across all six WHO regions (Figure 5). Local transmission has been reported in at least 12 countries across four WHO regions.

Figure 6. Countries, territories and areas reporting SARS-CoV-2 variant 501Y.V2 as of 16 February 2021

Variant P.1

Since our last update, variant P.1 has been reported in six additional countries. To date, this variant is reported in 21 countries across five of the six WHO regions (Figure 6). So far, local transmission has been reported in at least two countries in one WHO region.

Figure 7. Countries, territories and areas reporting SARS-CoV-2 variant P.1 as of 16 February 2021

A list of countries/territories/areas reporting variants of concern can be found in [Annex 2](#).

WHO regional overviews

African Region

In the past week, the African Region reported over 68 000 cases and 2500 deaths, a 20% and 21% decrease respectively compared to the previous week. This is the fourth consecutive week the Region reported decreases in both new cases and deaths. The highest numbers of new cases were reported in South Africa (16 363 new cases; 27.6 new cases per 100 000 population; a 33% decrease), Zambia (7027 new cases; 38.2 new cases per 100 000; a 13% decrease) and Nigeria (6422 new cases; 3.1 new cases per 100 000; a 26% decrease),

The countries reporting the highest number of new deaths in the past week were South Africa (1641 new deaths; 2.8 new deaths per 100 000; a 26% decrease), Zambia (101 new deaths; 0.5 new deaths per 100 000; a 7% increase), Nigeria (100 new deaths; <0.1 new deaths per 100 000; a 45% increase) and Malawi (100 new deaths; 0.5 new deaths per 100 000; a 33% decrease).

Region of the Americas

Over 1.3 million new cases and over 44 000 new deaths were reported in the Region of the Americas this week, a 16% and 2% decrease respectively compared to the previous week. The highest numbers of new cases were reported from the United States of America (673 630 new cases; 203.5 new cases per 100 000 population; a 23% decrease), Brazil (318 290 new cases; 149.7 new cases per 100 000; a 3% decrease) and Mexico (66 083 new cases; 51.3 new cases per 100 000; a 7% decrease).

The highest numbers of deaths were reported from the same countries, the United States of America (21 412 new deaths; 6.5 new deaths per 100 000; a 5% decrease), Mexico (8267 new deaths; 6.4 new deaths per 100 000; a 7% increase) and Brazil (7455 new deaths; 3.5 new deaths per 100 000; a 1% increase).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 170 000 new cases, a 7% increase compared to last week. The region reported just over 2500 new deaths, a 9% decrease. The three countries reporting the highest numbers of new cases continue to be the Islamic Republic of Iran (51 503 new cases; 61.3 new cases per 100 000 population; an 8% increase), United Arab Emirates (22 203 new cases; 224.5 new cases per 100 000; a 2% decrease) and Lebanon (19 156 new cases; 280.7 new cases per 100 000; a 1% increase).

The highest numbers of new deaths continue to be reported in the Islamic Republic of Iran (471 new deaths; 0.6 new death per 100 000 population; a 10% decrease), Lebanon (399 new deaths; 5.8 new death per 100 000; a 25% decrease) and Pakistan (362 new deaths; 0.2 new death per 100 000; a 24% increase).

European Region

The European Region reported over 960 000 new cases and over 28 000 new deaths, a decrease of 18% and 19% respectively when compared to the previous week. The three countries reporting the highest numbers of new cases were France (127 565 new cases; 195.4 new cases per 100 000; a 6% decrease), the Russian Federation (104 602 new cases; 71.7 new cases per 100 000; a 11% decrease), and the United Kingdom (97 271 new cases; 143.3 new cases per 100 000; an 27% decrease).

The highest numbers of deaths were reported from the United Kingdom (4816 new deaths; 7.1 new deaths per 100 000; a 26% decrease), the Russian Federation (3465 new deaths; 2.4 new deaths per 100 000, similar to previous week) and Germany (3443 new deaths; 4.1 new deaths per 100 000; a 25% decrease).

South-East Asia Region

In the past week, the South-East Asia Region reported over 150 000 new cases, a decrease of 13% compared to last week. The region reported over 2300 new deaths, a 9% decrease. The three countries reporting the highest numbers of new cases were India (78 577 new cases; 5.7 new cases per 100 000; a 2% decrease), Indonesia (63 693 new cases; 23.3 new cases per 100 000; a 21% decrease), and Sri Lanka (6276 new cases; 29.3 new cases per 100 000; a 19% increase).

The three countries reporting the highest numbers of new deaths this week were Indonesia (1543 new deaths; 0.6 new deaths per 100 000; a 7% decrease), India (646 new deaths; <0.1 new deaths per 100 000; a 11% decrease) and Bangladesh (76 new deaths; <0.1 new deaths per 100 000; a 4% decrease).

Western Pacific Region

The Western Pacific Region reported over 49 000 new cases the past week, a 20% decrease compared to the previous week. The region reported 1100 new deaths, a 13% decrease. The three countries reporting the highest numbers of new cases in the region this week were Malaysia (23 084 new cases; 71.3 new cases per 100 000; a 21% decrease), the Philippines (11 734 new cases; 10.7 new cases per 100 000; a 2% decrease), and Japan (11 037 new cases; 8.7 new cases per 100 000; a 34% decrease).

The three countries reporting the highest numbers of new deaths this week were Japan (574 new deaths; 0.5 new deaths per 100 000; a 16% decrease), the Philippines (397 new deaths; 0.4 new deaths per 100 000; a 10% decrease) and Malaysia (101 new deaths; 0.3 new deaths per 100 000; a 9% decrease).

Annex 3. Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case (Annex 1), or the detection of a variant of concern (Annex 2).

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that

are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.

- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 7 February 2021, 10 am CET

In this edition:

- [Global overview](#)
- [Special focus: How COVAX is distributing the first COVID-19 vaccines to prioritized countries in all six WHO regions](#)
- [Special focus: SARS-CoV-2 variants of concern](#)
- Region-specific information: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#)
- [Key Weekly Updates](#)

Global overview

For the fourth week in a row, the number of global new cases reported fell, with 3.1 million new cases last week, a 17% decline compared to the previous week (Figure 1). This is the lowest figure since the week of 26 October (15 weeks ago). Although there are still many countries with increasing numbers of cases, at the global level, this is encouraging. The number of new deaths reported also fell for a second week in a row, with 88 000 new deaths reported last week, a 10% decline as compared to the previous week. All WHO regions reported a decline in new cases, with five out of six regions reporting more than 10% decreases (Table 1). Europe and the Region of the Americas saw the greatest drops in absolute numbers, with together nearly 0.5 million fewer new cases reported last week (153 000 and 320 000 fewer new cases reported, respectively). New deaths also declined in all regions except the Western Pacific, where mortality rates remained similar to the previous week.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 7 February 2021**

**See [data](#), [table](#) and [figure notes](#)

In the past week, the five countries reporting the highest number of new cases continue to be the United States of America (871 365 cases, a 19% decrease), Brazil (328 652 cases, a 10% decrease), France (136 154 cases, a 4% decrease), the United Kingdom of Great Britain and Northern Ireland (133 747 cases, a 25% decrease), and the Russian Federation (116 842 cases, a 11% decrease).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 7 February 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 568 167 (50%)	-17%	46 913 218 (44%)	45 350 (51%)	-4%	1 092 521 (47%)

Special Focus: How COVAX is distributing the first COVID-19 vaccines to prioritized countries in all six WHO regions

The [Access to COVID-19 Tools Accelerator](#) (ACT-Accelerator) was formed ten months ago with two aims: first to develop COVID-19 vaccines, diagnostics and therapeutics fast, and second, to distribute them fairly. The first aim has been achieved. As WHO Director-General Dr Tedros said in his [opening remarks at the High-Level Finance Ministers' Meeting for the ACT Accelerator](#) on 29 January: "The development and approval of safe and effective vaccines less than a year after the emergence of a new virus is a stunning scientific achievement, and a much-needed source of hope."

However, in opening remarks at a media briefing on COVID-19 on [5 February](#), he highlighted that around 130 countries, with 2.5 billion people, were yet to administer a single dose. More than 90% of the countries now rolling out vaccines are high- or upper-middle income countries. Seventy-five percent of doses have been deployed in only 10 countries. At the [148th session of the Executive Board](#), Dr Tedros stressed that "Vaccine equity is not just a moral imperative, it is a strategic and economic imperative." The International Chamber of Commerce Research Foundation found in a study that "the global economy stands to lose as much as \$9.2 trillion if governments fail to ensure developing economy access to COVID-19 vaccines, as much as half of which would fall on advanced economies."¹ Once countries with vaccines have vaccinated their own health workers and older people, the best way to protect the rest of their own population is to share vaccines so other countries can do the same. The longer it takes to vaccinate those most at risk everywhere, the more opportunity the virus has to mutate and evade vaccines.

[COVAX](#), the vaccines pillar of the ACT-Accelerator with 190 participating economies, is supporting the fair distribution of vaccines, and has secured 2 billion doses from five producers, with options on more than 1 billion more doses. A total of 44 bilateral deals were signed last year, and a further 12 signed this year. In this Special Focus, we present how COVAX is receiving and distributing an exceptional first round allocation of 1.2 million doses of the Pfizer-BioNTech vaccine in the first quarter of 2021 to prioritised participants, and 336 million doses of the AstraZeneca/Oxford vaccine.

Following a letter sent to the 190 COVAX participants, as of the deadline of 18 January, 72 expressions of interest were received for the exceptional first round allocation of the ultra-cold chain vaccine from Pfizer-BioNTech. Six regional review committees (composed of staff from WHO, UNICEF, Gavi and members of Gavi's Independent Review Committee) undertook a technical assessment of the applications. Due to the limited quantities of the first wave of vaccines, the list of participants was then narrowed down based on the following considerations; priority was given to COVAX participants that had not started COVID-19 vaccination (as of 29 January 2021), met all of the readiness criteria (including being able to manage the ultra-cold chain vaccine storage at -70°C) and, for self-financing participants, were within the Pfizer price point; this left a total of 51 participants. Participants were then grouped by WHO Region and advance market commitment/self-financing status to ensure all Regions/groups would be represented. Participants in each group were ranked by their 28-day mortality rate as a proxy for the risk of health care worker exposure (i.e. high COVID-19 mortality = high exposure). Eligible COVAX participants were selected from each group up to the 18 maximum that could be covered and supported by the 1.2 million doses. The doses will be delivered in the first quarter of 2021. For more details on the selection factors and countries chosen for the initial COVAX vaccine distribution see the [interim distribution forecast](#). This document complements the recently published [COVAX global supply forecast](#).

¹ International Chamber of Commerce Research Foundation (2021) 'Study shows vaccine nationalism could cost rich countries US\$4.5 trillion' Retrieved from: <https://iccwbo.org/media-wall/news-speeches/study-shows-vaccine-nationalism-could-cost-rich-countries-us4-5-trillion/>

A further 336 million AstraZeneca/Oxford vaccine doses (240 million doses produced by the Serum Institute of India and 96 million doses produced by AstraZeneca) will be delivered in the first and second quarters of 2021. The combined population coverage of these initial doses will cover, on average, 3.3% of the total population of the 145 participants receiving doses. This is in line with the COVAX target to reach at least 3% population coverage in all countries, territories and areas in the first half of the year, enough to protect the most vulnerable groups such as health care workers.

COVAX is aiming to have 2 billion doses distributed, including at least 1.3 billion doses to 92 lower income economies, by the end of 2021, protecting at least 20% of each participating population (unless a participant has requested a lower percentage of doses). However, to achieve this, there needs to be prompt and equitable dose sharing, and support to close the funding gap of US\$26 billion for the ACT-Accelerator this year, including US\$7.8 billion for COVAX. This year the theme for World Health Day is 'health inequality.' The WHO Director-General [has challenged](#) Member States to ensure that by the time World Health Day arrives on 7 April, COVID-19 vaccines are being administered in every country. To support Member States in this endeavor, WHO has a [COVID-19 vaccine country readiness and delivery portal](#), which includes guidance and tools, training (including two free online courses on [OpenWHO.org](#)), and answers to frequently asked questions.

Special Focus: Update on SARS-CoV-2 variants of concern

WHO is closely monitoring the public health events associated with SARS-CoV-2 variants and continues to provide updates as new information becomes available (see: [Disease Outbreak News](#) and [Weekly Epidemiological Updates](#)). WHO is working with member states, external partners and experts to evaluate the available evidence around transmissibility, severity, and to assess the potential impacts on countermeasures including vaccines, diagnostics, therapeutics, and public health and social measures (PHSM). Here we provide an update on ongoing studies and the geographical distribution of three variants of concern (VOCs) as reported by countries, territories and areas (hereafter countries) as of 8 February 2021. Emerging evidence is summarized in Table 3 below.

The reported geographical extent of VOC detections has continued to increase as local and national surveillance activities are adapted and strengthened to include strategic sequencing to detect cases with SARS-CoV-2 variants. Since our last update, an additional 6 countries have reported cases of variants VOC202012/01, 3 additional countries reported variant 501Y.V2, and 5 additional countries reported variant P.1 (Table 3, Figures 3,5,7). In many countries, detections remain limited to imported cases only; however, VOCs are increasingly being identified among a subset of community-based samples with no direct links to travellers. Local transmission of VOC202012/01 has been reported in a growing number of countries in the European Region and in some areas of North America. Similarly, there is evidence to suggest that 501Y.V2 transmission is occurring in several countries in the African Region, with clusters of cases or ongoing local transmission suggested in countries in other regions.

On 2 February, the WHO Virus Evolution Working Group convened a meeting with GISAID, Nextstrain and Pango (three prominent systems for tracking the genomic evolution of SARS-CoV-2) and other experts to discuss mechanism for designating variants of concern and labeling these with unbiased, easy to pronounce names. While work is ongoing to establish standardized nomenclature for VOCs, WHO urges authorities, researchers, media and the general public to use non-stigmatizing nomenclature and language for describing VOCs. The group met again today to further discussions and propose a nomenclature.

The emergence of new variants has highlighted the importance of countries continuing to strengthen the PHSM (for more information, please see our [technical guidance](#)). As countries work to prepare for and rollout COVID-19 vaccines while continuously adapting other PHSM, it is essential to incorporate studies to investigate potential impacts of emerging VOCs on transmission, disease, and the effectiveness of countermeasures, and to continuously share findings with the global community.

Table 3: Summary of emerging information on key variants of concern, as of 8 February 2021

Nextstrain clade	20I/501Y.V1	20H/501Y.V2 [†]	20J/501Y.V3
Pango lineage	B.1.1.7	B.1.351	B.1.1.28
GISAID clade	GR	GH	GR
Alternate names	VOC202012/01 [†]	VOC202012/02	P.1 [†]
First detected by	United Kingdom	South Africa	Brazil / Japan
First appearance	20 September 2020	Early August 2020	December 2020
Key mutations	<ul style="list-style-type: none"> N501Y D614G 69/70 deletion 144Y deletion A570D E484K (detected only in 11 sequences)¹ 	<ul style="list-style-type: none"> N501Y D614G E484K K417N 	<ul style="list-style-type: none"> N501Y D614G E484K K417N
Transmissibility*	Increased ⁽¹⁾ (36%-75%) ⁽²⁾ , increased secondary attack rate ⁽³⁾ (10% to 13%)	Increased [1.50 (95% CI: 1.20-2.13) times more transmissible than previously circulating variants] ^(4,6)	Suggested to be increased
Severity*	Mixed evidence, potential increased mortality based on epidemiological observations ^(1,5)	No impact reported to date ^(4,6) , no significant change in-hospital mortality ⁽¹⁷⁾	Under investigation, no impact reported to date
Neutralization capacity*	Slight reduction but overall neutralizing titers still remained above the levels expected to confer protection ⁽⁷⁾	Decreased, suggesting potential increased risk of reinfection ^(4,8)	Potential decrease, small number of reinfections reported ^(18,19)
Potential impacts on vaccines*	No significant impact on Moderna, Pfizer-BioNTech, and Oxford-AstraZeneca vaccines ⁽⁹⁻¹²⁾	Moderna and Pfizer-BioNTech: Reduction in the neutralizing activity, but impact on protection against disease not known. ⁽⁹⁻¹²⁾ Novavax and Johnson & Johnson: Lower vaccine efficacy in South Africa compared to settings without the variant (press release data only). Moderate-severe disease were assessed. Serologic neutralization results pending. ^(13,14) Oxford/AstraZeneca: Minimal vaccine efficacy against mild-moderate COVID-19 disease, with wide confidence intervals (press release data only), impact on severe disease undetermined. Serologic neutralization substantially reduced compared with original strains, based on small number of samples analyzed. ^(15,16)	Potential reduction, under investigation
Potential impacts on diagnostics*	S gene target failure. ⁽¹⁵⁾ No impact on Ag RDTs observed ⁽²⁰⁾	None reported to date.	None reported to date.
Countries reporting cases (newly reported in last week)**	86 (6)	44 (3)	15 (5)

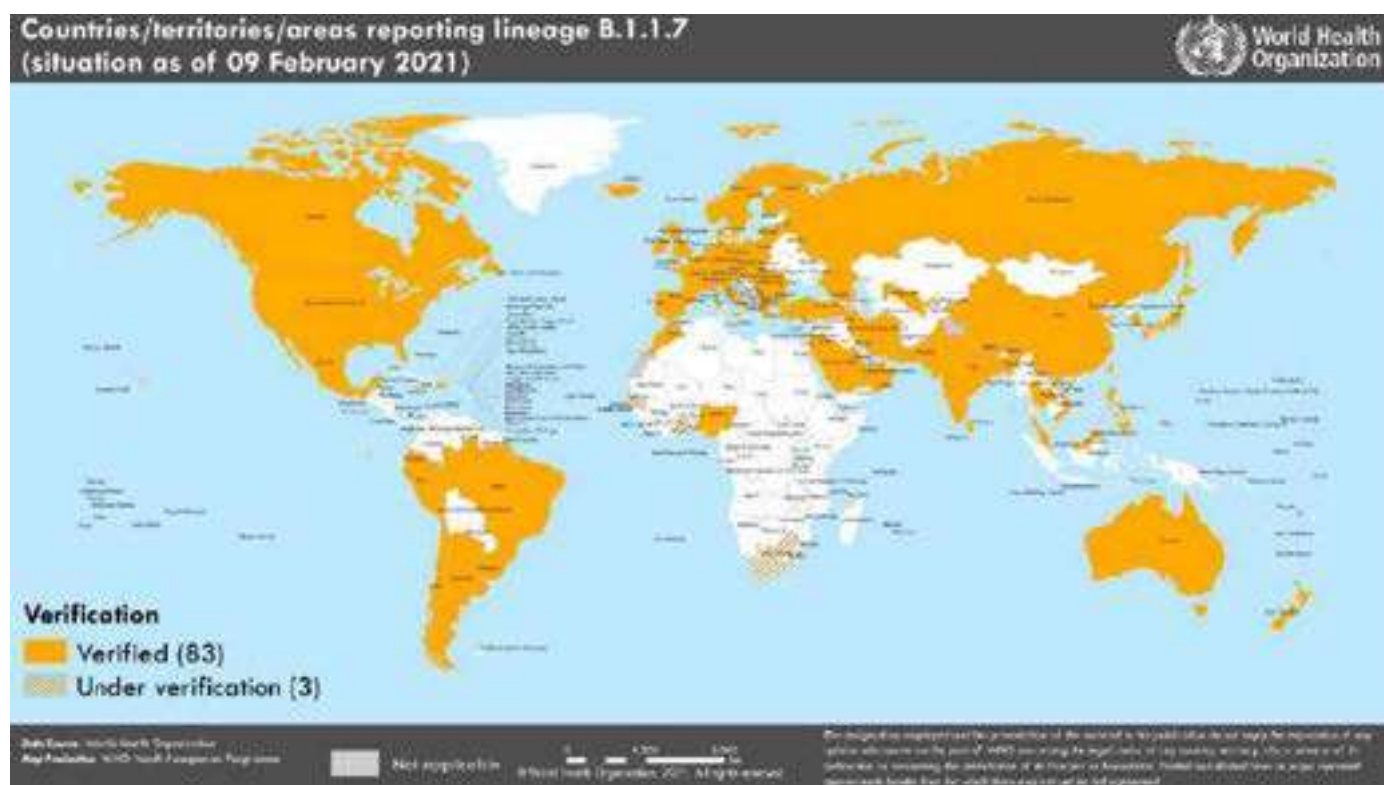

*Generalized findings as compared to non-VOC viruses. Based on emerging evidence from multiple countries, including non-peer-reviewed preprint articles and reports from public health authorities and researchers – all subject to ongoing investigation and continuous revision.

**Includes official and unofficial reports of VOCs detections in countries among either travellers (imported cases only) or community samples (local transmission).

[†]While work is ongoing to establish standardized nomenclature for key variants, these are the names by which WHO will refer to them in this publication.

Variant VOC 202012/01

Figure 3. Countries, territories and areas reporting SARS-CoV-2 VOC 202012/01 as of 9 February 2021

As mentioned in previous publications, the VOC 202012/01 variant has shown increased transmissibility, including increased secondary attack rates, and some evidence of increase in disease severity based on preliminary findings (1,3). More recently, results from a Phase 3 trial conducted by Novavax demonstrated an efficacy of 85.6% against this variant in the United Kingdom (14).

While previously mentioned preliminary studies showed post-vaccination sera with Pfizer-BioNTech and Moderna vaccines had limited to no significant change against the VOC202012/01 variant, recently, the E484K mutation in the spike protein has been detected in 11 sequences within the B.1.1.7 lineage in the United Kingdom (7,9-12,20,21). This mutation is also found in 501Y.V2 and P.1 variant, but the three variants have arisen separately and are not linked to each other (3). Mutation E484K has been identified as an “escape mutation,” which has shown the ability to reduce the neutralising activity by monoclonal antibodies or convalescent sera. A preliminary study has shown further reduction in neutralization activity by vaccine elicited antibodies if E484K mutation is present alongside the VOC202012/01 variant (22). The detected E484K mutation within this lineage is currently limited to a small number of cases, and these are all preliminary findings which require further investigation involving larger sample sizes.

In the United Kingdom where this variant was initially identified, the proportion of cases with VOC202012/01 among tested samples has increased from 63% in week commencing 14 December, to 90% in week beginning 18 January 2021 (1). This high rate of detection of VOC202012/01 has persisted in recent weeks while the case and death counts are showing a declining trend (1). From 11 January through 7 February, a decreasing trend has been observed, following the implementation of stringent public health and social measures (Figure 4).

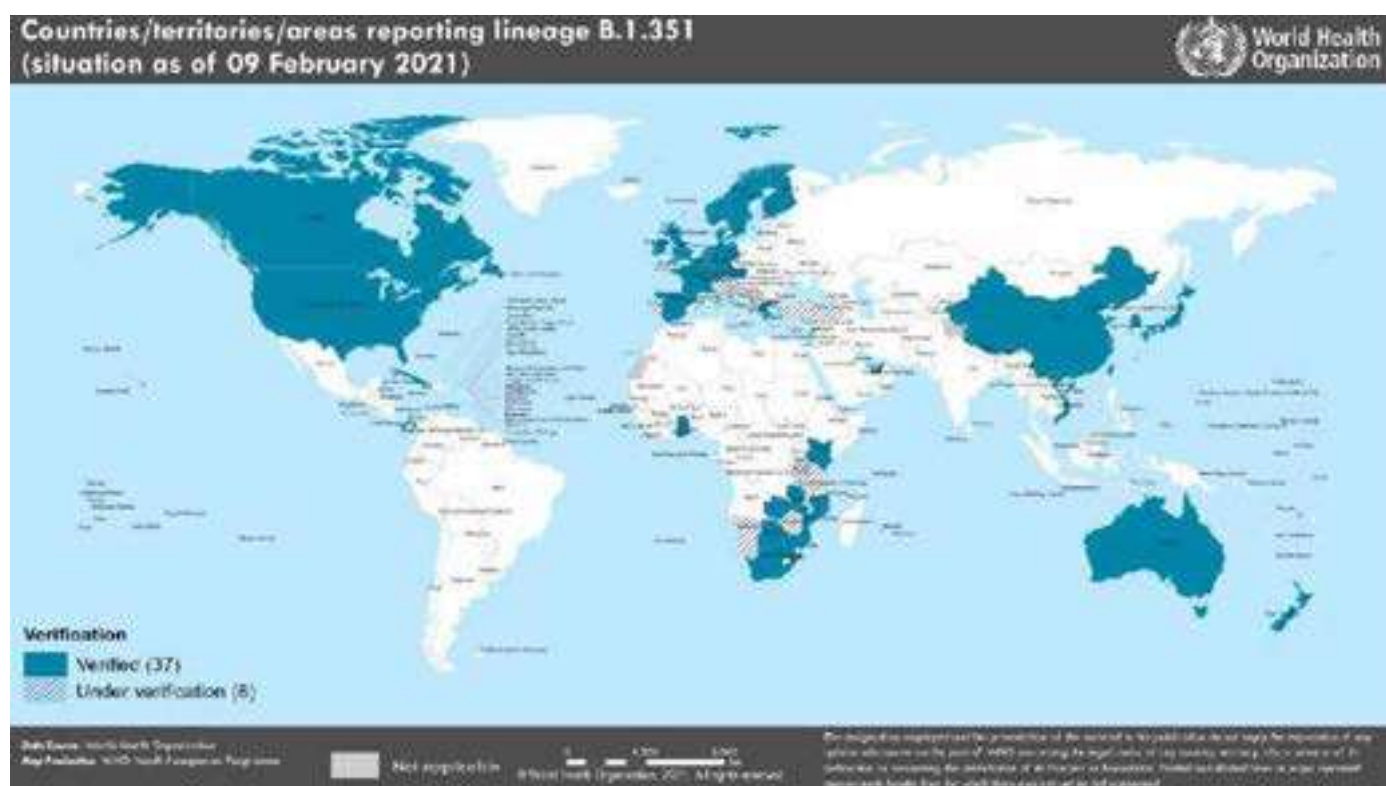

Similarly, in other European countries such as Ireland and Denmark, a marked increasing trend in the number of new COVID-19 cases was detected in late December 2020 as the countries were reporting local transmission of VOC202012/01. In Ireland, local authorities have reported the proportion of cases with VOC202012/01 among tested samples reached over 63% in the week starting on the 25 January and over 7% in Denmark the week starting the 11 January 2021. Implementation of more intensive public health and social measures at the end of December and beginning of January led to marked declines in COVID-19 case and death incidence in both countries.

Figure 4: Weekly COVID-19 cases per 1 million population in the United Kingdom, as of 7 February 2021

Variant 501Y.V2

Figure 5: Countries, territories and areas reporting SARS-CoV-2 501Y.V2 as of 9 February 2021

As mentioned in previous publications, the 501Y.V2 variant has shown increased transmissibility (4,6), and laboratory-based studies noted a small reduction in the neutralizing activity against SARS-CoV-2 501Y.V2 variants in individuals vaccinated with the Moderna or Pfizer-BioNTech vaccines, although the neutralizing titers still remained above the levels expected to confer protection (4,8-12).

New preliminary results of Novavax, Johnson & Johnson, and Oxford/AstraZeneca vaccines have shown potential reduced effectiveness against 501Y.V2. Phase 3 trials of the Johnson & Johnson vaccine found 66% effectiveness in preventing moderate to severe infections, 28 days after vaccination; however, the efficacy varied across the three trial locations: the South Africa efficacy (57%) was lowest, and reflects 95% of the disease causing strains were the variant (13). Similar preliminary results from Novavax have shown 60%

efficacy against 501Y.V2 (14). In a small trial of approximately 2200 subjects in South Africa, a two-dose regimen of the Oxford/AstraZeneca vaccine resulted in a non-significant efficacy of 21.9% against mild-moderate COVID-19 which included a period when the majority of cases were caused by 501Y.V2; however, efficacy against severe COVID-19, hospitalizations and deaths was not studied (15,16). Serologic neutralization was substantially reduced compared with original strains, based on small number of samples analysed. Notably, primary analysis of data from Phase III trials in the context of viral settings without this variant have shown that the AstraZeneca/Oxford vaccine offers protection against severe disease, hospitalisation and death; therefore, it remains vitally important to determine the vaccine's effectiveness for preventing more severe illness caused by the 501Y.V2 variant (22).

It is important to note that these are preliminary findings which require further investigation including the need for assessment of vaccine performance against severe disease, assessment of neutralizing activity in a larger number of samples and for other vaccines against this strain, an evaluation of changes in neutralization on clinical efficacy and eventually, an estimate of the effectiveness of these vaccines on the current emerging variants. Manufacturers are concurrently exploring potential ways to improve protection against emerging VOCs, such as augmenting dosages and dosage intervals, introducing booster doses or booster vaccines, and beginning work to adapt vaccines and optimize production pipelines to allow for rapid strain changes, should this become necessary.

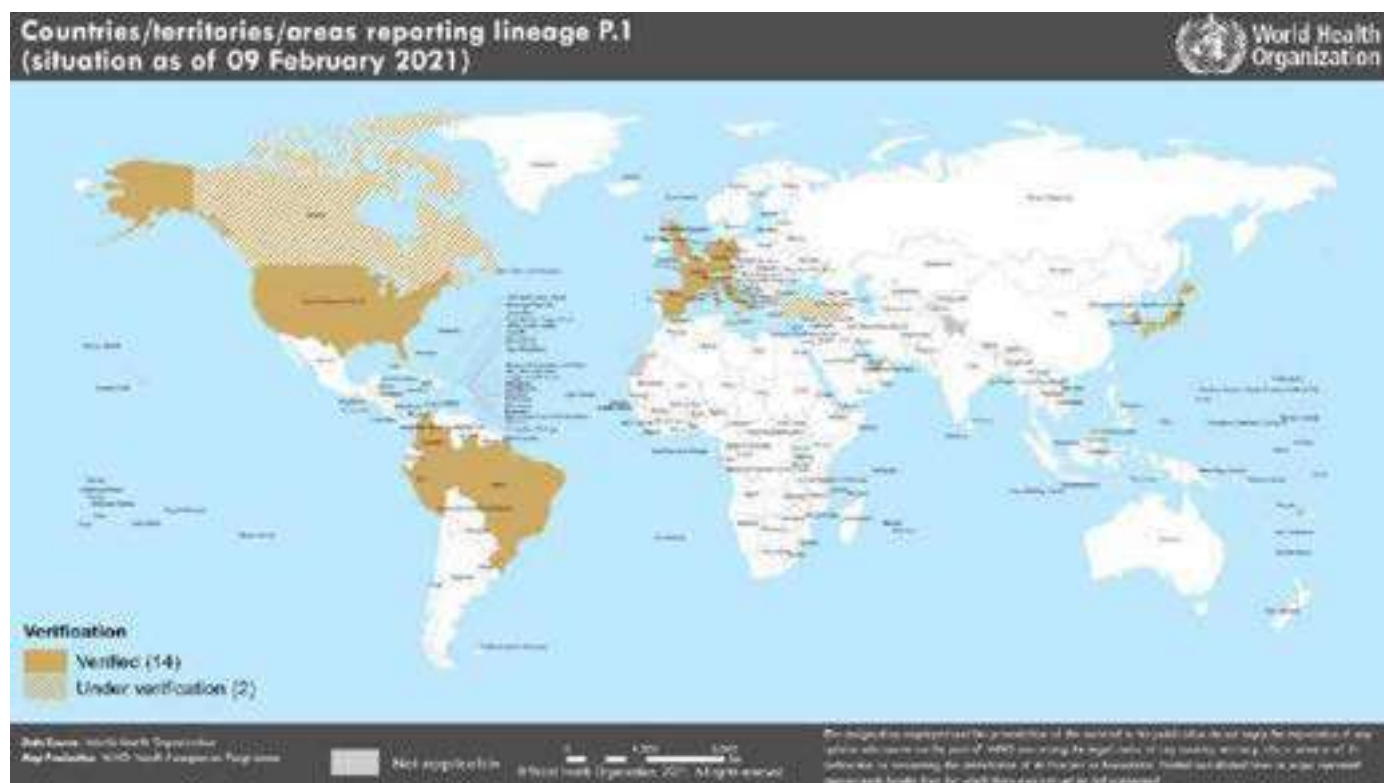

In South Africa, where this variant was initially identified, a progressive decreasing trend in case and death incidence (Figure 6), has been observed following the implementation of stringent PHSM. Here, studies have shown that the second wave (predominated by 501Y.V2 circulation) was associated with a higher incidence, faster increases in cases and hospitalizations, and increased mortality risk in weeks with high rates of hospital admission reflecting increased pressure on the health system. However, it was not associated with increased in-hospital mortality (17) – suggesting disease severity may be similar to previously circulating variants.

Figure 6. Weekly COVID-19 cases per 1 million population in South Africa, as of 7 February 2021

Variant P.1

Figure 7. Countries, territories and areas reporting SARS-CoV-2 P.1 variant as of 9 February 2021

In Brazil, where the P.1 variant was initially identified in addition to detection in a group of travellers from Brazil to Japan, a second wave of cases and corresponding deaths was observed with increasing trends beginning late November 2020, but has shown early signs of waning this week (Figure 8). In Manaus, Brazil, the proportion of cases with P.1 among tested samples have increased from 52% in December 2020 to 85% in January 2021 (23). Based on preliminary investigations, the mutations detected in P.1 variant could potentially reduce antibody neutralization (18); however, additional studies are required to assess if there are changes in transmissibility, severity or antibody neutralizing activity as a result of this new variants.

Situation by WHO Region

African Region

In the past week, the African Region reported over 84 800 cases and just over 3200 deaths, a 22% decrease in cases and a 30% decrease in deaths respectively compared to the previous week. This is the third consecutive week the region reported decreases in both new cases and deaths. The highest numbers of new cases were reported in South Africa (24 464 new cases; 41.2 new cases per 100 000 population; a 45% decrease), Nigeria (8685 new cases; 4.2 new cases per 100 000; a 13% decrease) and Zambia (8075 new cases; 43.9 new cases per 100 000; an 8% decrease).

The countries reporting the highest number of new deaths in the past week were South Africa (2229 new deaths; 3.8 new deaths per 100 000; a 34% decrease), Malawi (150 new deaths; 0.8 new deaths per 100 000; a 31% decrease) and Zimbabwe (123 new deaths; 0.8 new deaths per 100 000; a 44% decrease).

Region of the Americas

Over 1.5 million new cases and over 45 000 new deaths were reported in the Region of the Americas this week, a decrease of 17% in cases and a decrease of 4% in deaths compared to the previous week. The highest numbers of new cases were reported from the United States of America (871 365 new cases; 263.3 new cases per 100 000 population; a 19% decrease), Brazil (328 652 new cases; 154.6 new cases per 100 000; a 10% decrease) and Mexico (70 978 new cases; 55.1 new cases per 100 000; a 35% decrease).

The highest numbers of deaths were reported from the same countries, the United States of America (22 562 new deaths; 6.8 new deaths per 100 000; a 0.2% increase), Mexico (7711 new deaths; 6.0 new deaths per 100 000; a 14% decrease) and Brazil (7368 new deaths; 3.5 new deaths per 100 000; a 1% decrease).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 158 600 new cases, a decrease of 2% compared to last week. The region reported 2761 new deaths, a 16% decrease. The three countries reporting the highest numbers of new cases continue to be the Islamic Republic of Iran (47 639 new cases, 56.7 new cases per 100 000 population, a 7% increase), United Arab Emirates (22 741 new cases, 229.9 new cases per 100 000, 13% decrease) and Lebanon (18 923 new cases, 277.2 new cases per 100 000, a 15% decrease).

The highest numbers of new deaths continue to be reported in Lebanon (531 new deaths, 7.8 new death per 100 000, an 29% decrease), Islamic Republic of Iran (523 new deaths, 0.6 new death per 100 000 population, a 12% decrease), and Tunisia (482 new deaths, 4.1 new death per 100 000, a 8% decrease).

European Region

The European Region reported over 1.1 million new cases and over 33 000 new deaths, a decrease of 19% and 13% respectively when compared to the previous week. The three countries reporting the highest numbers of new cases were France (136 154 new cases; 208.6 new cases per 100 000, a 3% decrease), the United Kingdom (133 747 new cases, 197 new cases per 100 000, a 25% decrease), and the Russian Federation (116 842 new cases, 80.1 new cases per 100 000, an 11% decrease).

The highest numbers of deaths were reported from the United Kingdom (6521 new deaths; 9.6 new deaths per 100 000, a 21% decrease), Germany (4572 new deaths; 5.5 new deaths per 100 000, a 10% decrease) and the Russian Federation (3479 new deaths; 2.4 new deaths per 100 000, a 6% decrease).

South-East Asia Region

In the past week, the South-East Asia region reported over 177 000 new cases, a decrease of 12% compared to last week. The region reported 2560 new deaths, a 21% decrease. The three countries reporting the highest numbers of new cases and new deaths were Indonesia (80 697 new cases; 29.5 new cases per 100 000; a 9% decrease), India (80 180 new cases; 5.8 new cases per 100 000, a 12% decrease), and Sri Lanka (5283 new cases; 24.7 new cases per 100 000; a 7% decrease).

The three countries reporting the highest numbers of new deaths this week remain Indonesia (1665 new deaths; 0.6 new deaths per 100 000, a 19% decrease), India (722 new deaths; 0.1 new deaths per 100 000, a 23% decrease)

and Bangladesh (79 new deaths; <0.1 new deaths per 100 000; a 27% decrease).

Western Pacific Region

The Western Pacific Region reported over 61 700 new cases the past week, a 14% decrease compared to the previous week. The region reported 1297 new deaths, a 1% increase. The three countries reporting the highest numbers of new cases in the region this week were Malaysia (29 060 new cases; 89.8 new cases per 100 000, a 0.5% decrease), Japan (16 693 new cases; 13.2 new cases per 100 000, a 36% decrease), and the Philippines (12 005 new cases; 11 new cases per 100 000, a 1.4% increase).

The three countries reporting the highest numbers of new deaths this week were Japan (684 new deaths; 0.5 new deaths per 100 000, an 8% increase), the Philippines (441 new deaths; 0.4 new deaths per 100 000, an 8% decrease) and Malaysia (111 new deaths; 0.3 new deaths per 100 000, a 40%

increase).

Key Weekly Updates

WHO Director-General Dr Tedros' remarks

- *Do not rush to reopen*

Now as we begin to roll out vaccines, we must remember that vaccines alone will not control this pandemic. It is vital that governments do not rush to re-open, and that they continue public health measures to prevent the spread of the virus.

[Opening remarks at the Member States briefing on COVID-19 - 4 February 2021](#)

- *Sharing vaccines to protect the population*

Once countries with vaccines have vaccinated their own health workers and older people, the best way to protect the rest of their own population is to share vaccines so other countries can do the same. That's because the longer it takes to vaccinate those most at risk everywhere, the more opportunity we give the virus to mutate and evade vaccines.

- *Scaling-up the manufacturing process*

We need a massive scale-up in production. Manufacturers can do more: having received substantial public funding, we encourage all manufacturers to share their data and technology to ensure global equitable access to vaccines.

- *Sharing dossiers with WHO for emergency listing*

We call on companies to share their dossiers with WHO faster and more fully than they have been doing, so we can review them for emergency use listing.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. A record of historic data adjustment made is available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data. Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its

authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see:

[Considerations for implementing and adjusting public health and social measures in the context of COVID-19:](#)

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 31 January 2021, 10 am CET

For the latest data and other updates on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Globally, 3.7 million new cases were reported last week, a 13% decline as compared to the previous week, and the third consecutive week showing a decline in cases. There were 96 000 new deaths, and a 1% decline as compared to the previous week, (Figure 1). This brings the total number of cases to over 102 million and the total number of deaths to 2.2 million from 222 countries and territories. Last week, all WHO regions, except South-East Asia reported a decline in new cases (Table 1). Although new deaths declined globally by 1%, they rose in the Western Pacific (21%), Eastern Mediterranean (9%), and the Americas (4%).

Saturday 30 January 2021 marked one year since WHO declared COVID-19 a Public Health Emergency of International Concern. At that time, there were 9826 cases in 20 countries, and 213 deaths in one country (all of which were in China).

In the past week, the five countries reporting the highest number of new cases continue to be the United States of America (1 072 287 cases, a 15% decrease), Brazil (364 593 cases, a 1% increase), the United Kingdom of Great Britain and Northern Ireland (178 629 cases, a 31% decrease), France (141 092 cases, a 2% increase) and the Russian Federation (131 039 cases, a 13% decrease).

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 31 January 2021**

**See [data](#), [table](#) and [figure notes](#)

In this edition of the COVID-19 Weekly Epidemiological Update, special focus updates are provided on:

- [COVID-19 and Health Workers](#)
- [SARS-CoV-2 variants of concern](#)
- Additional Region-specific information: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#)
- [Key Weekly Updates](#)

Note: From 3 February 2021, a daily log of major changes and errata in WHO daily aggregate case and death count data will no longer be published [online](#). A record of historic data adjustment made will continue to be available upon request by emailing epi-data-support@who.int. Please specify the country(ies) of interest, time period(s), and purpose of the request/intended usage.

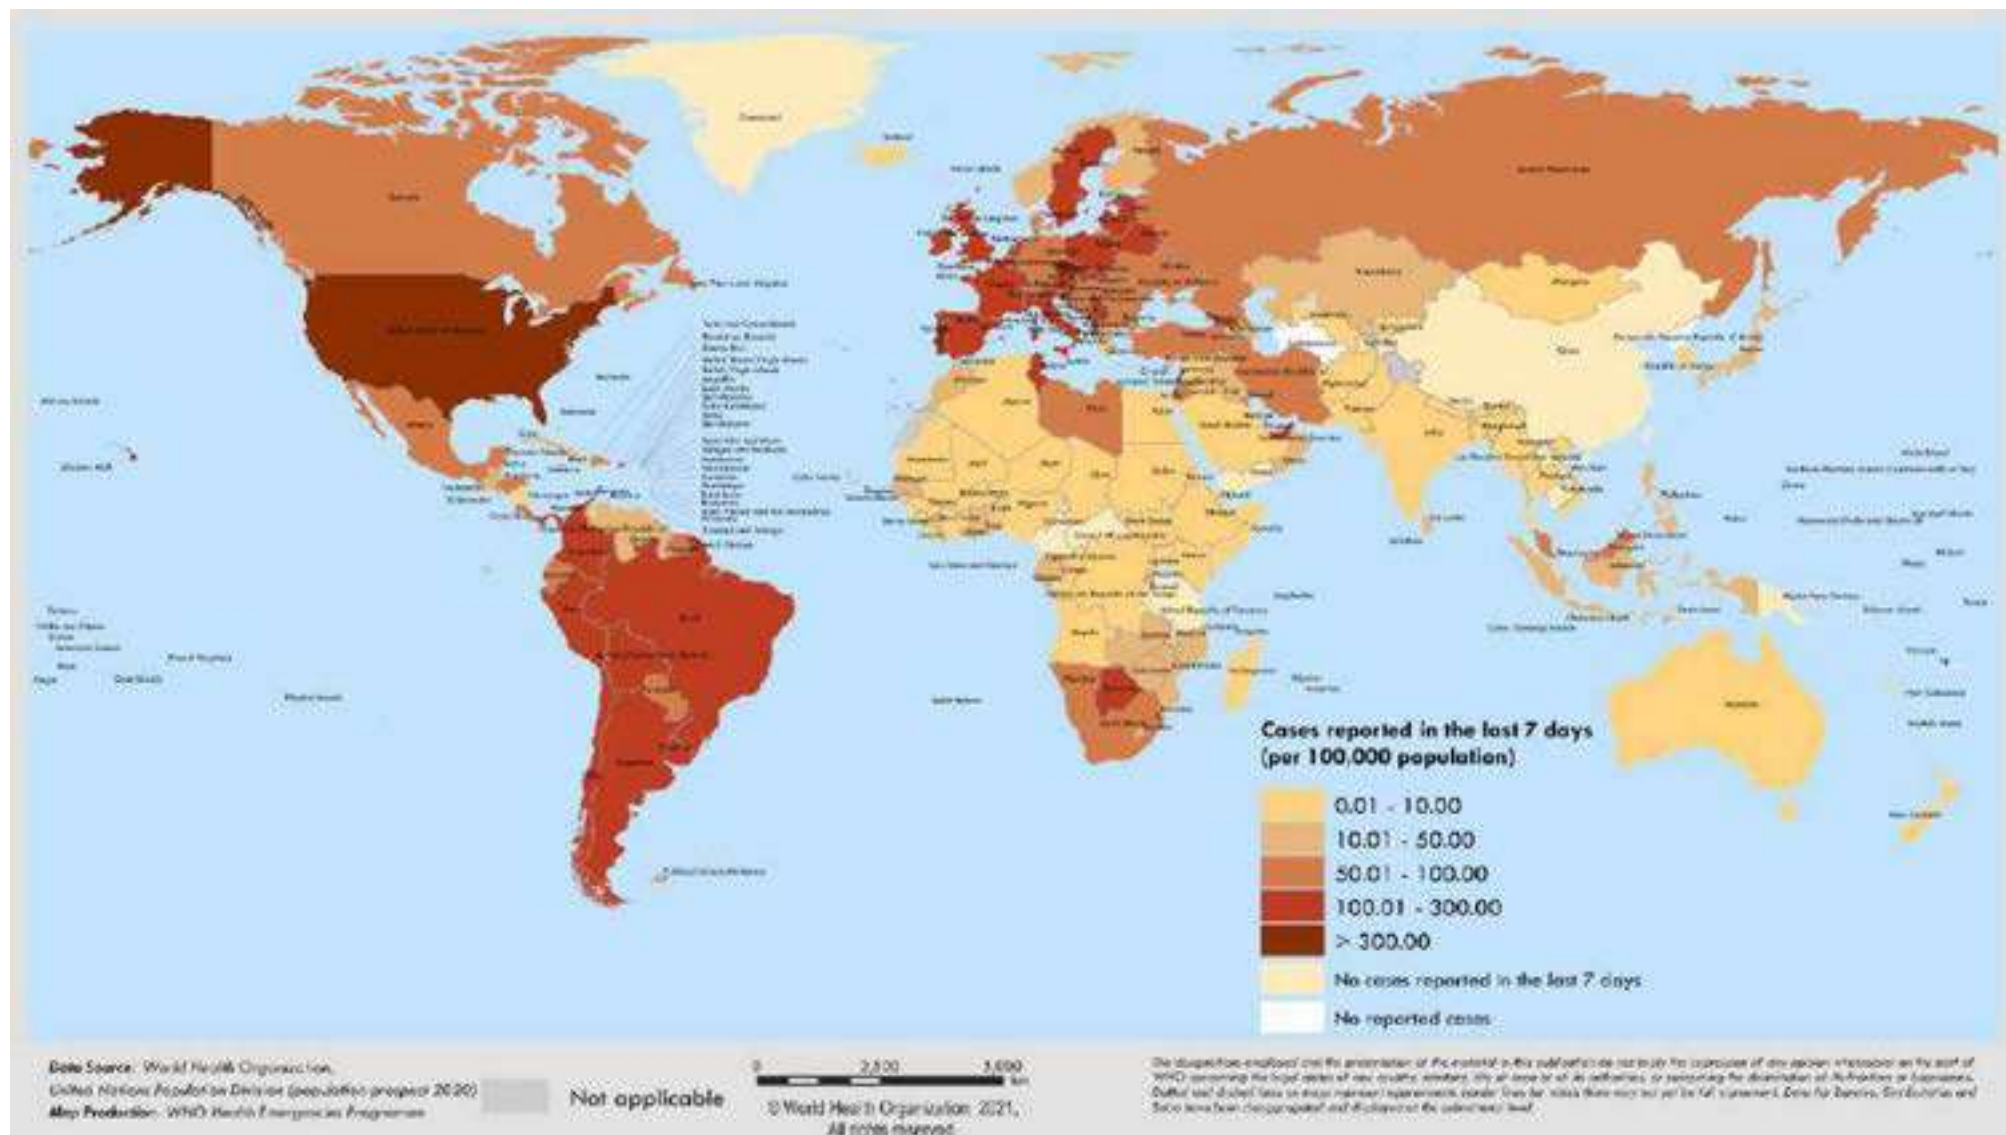

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 31 January 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	1 888 070 (51%)	-11%	45 345 051 (44%)	47 277 (49%)	4%	1 047 171 (47%)
Europe	1 255 352 (34%)	-18%	34 276 814 (34%)	36 674 (38%)	-8%	745 590 (34%)
South-East Asia	200 219 (5%)	3%	12 856 723 (13%)	3 258 (3%)	0%	197 707 (9%)
Eastern Mediterranean	161 943 (4%)	-5%	5 669 940 (6%)	3 272 (3%)	9%	134 189 (6%)
Africa	108 391 (3%)	-27%	2 570 474 (3%)	4 602 (5%)	-8%	62 504 (3%)
Western Pacific	72 135 (2%)	-11%	1 420 024 (1%)	1 281 (1%)	21%	24 588 (1%)
Global	3 686 110 (100%)	-13%	102 139 771 (100%)	96 364 (100%)	-1%	2 211 762 (100%)

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior. Regional percentages rounded to the nearest whole number, global totals may not equal 100%.

**See [data](#), [table](#) and [figure](#) notes.

Figure 2. COVID-19 cases per 100 000 population reported in the last seven days by countries, territories and areas, 25 January through 31 January 2021**

Special Focus: COVID-19 and Health Workers

Overview

In his [press briefing of 29 January 2021](#), WHO Director-General Dr Tedros again emphasized that healthcare workers have been at the forefront of the response to the pandemic but are often under-protected and over-exposed. He reiterated his 18 January 2021 call to action: for governments and industry leaders to work together to ensure that in the first 100 days of 2021, vaccination of health workers and older people is underway in all countries.

In this Special Focus – recognizing that 2021 has been designated as the [International Year of Health and Care Workers](#) – we present an overview of health worker SARS-CoV-2 infections using data collected via the WHO Global Surveillance systems, and analyse risk factors from available scientific literature.

To date, a total of 183 countries have reported data via WHO Case Report Forms (CRFs) to date, covering 37 million cases (36% of current global COVID-19 cases). The CRFs were mainly received from Member States in the Region of the Americas and European Region. Over 16 million CRFs (43% of CRFs received, representing 16% of global COVID-19 cases) included information on occupation status, including health workers¹. Within this subset, health workers accounted for close to 1.29 million COVID-19 cases, or 8% of cases. The median age of health worker cases was 42 years (interquartile range 27 to 60 years), and 68% were women. This is in line with the [proportion of women working in the health and social sectors](#) globally.

At the outset, it is important to mention that the analyses based on CRF data provided to WHO has limitations, mainly due to variations in reporting coverage and completeness, reporting methods, some irregularity of weekly reports, health worker definitions, and lack of information about the setting of exposure. WHO advises Member States to use the definition of health workers as stated in the [Surveillance Protocol](#) for SARS-CoV-2 infection.²

Percentage of health worker infections and relative risk over time

It is important to acknowledge that country-specific trends remain highly variable, and the data are based on reported cases (those testing positive for SARS-CoV-2) often without providing information on the overall number tested. Therefore, it is difficult to reliably compare incidence of health worker infections over time and trends should be interpreted with caution due to variations in reporting coverage and completeness, adaptations to testing strategies, differences in the implementation of public health measures and interventions, as well as differences in the circulation of SARS-CoV-2 in the community over time. Additionally, it is not possible to determine the place of exposure (e.g., health care facility or community) among health workers from WHO CFR data.

Based on WHO CRF data, in the first three months of the pandemic, health worker infections slightly exceeded 10% of reported cases (Figure 3), declining to less than 5% by early-June 2020 (Epi week 2) and to approximately 2.5% by September 2020 (Epi week 37).

¹ For the purposes of the case-based surveillance, 'health workers' were defined as those working "any job in a health care setting".

² The term "health worker" includes allied health workers and auxiliary health workers such as cleaning and laundry personnel, x-ray physicians and technicians, clerks, phlebotomists, respiratory therapists, nutritionists, social workers, physical therapists, laboratory personnel, cleaners, admission/reception clerks, patient transporters, catering staff and so on).

Figure 3: Weekly total number of cases, and percentage of health worker cases among infected individuals reported, data from WHO Case Report Forms where occupation was indicated, 20 January 2020 to 31 January 2021.

A relative risk measure (dividing the rate of health worker infections by that of the non-health workers) was calculated for each week by estimating the total number of health workers and non-health workers. The rate of health worker infections was calculated by dividing their number by all workers employed in the health and social sector. A similar rate of infection was calculated for non-health workers relative to the general population size. It must be noted that there has likely been surveillance bias and differences in testing of health workers compared to general population, particularly early on. Based on the data we have available, it is observed that health workers experienced more than triple the risk of infection as that of the general population in the period between mid-March to mid-May 2020. A similar level of relative risk³ was also reported by an observational cohort study of about 2 million community individuals and 100 000 front-line health-care workers in the United Kingdom of Great Britain and Northern Ireland, and the United States of America. Our data suggests this period of elevated risk was followed by a steep decline to that found in the general population by end of May 2020.

Analysis of health worker risk factors

WHO first commissioned a rapid systematic review of published literature on the risk factors in health workers for SARS-CoV-2 infections in April 2020 and this has been updated regularly since. The latest update on 24 December 2020 identified a total of 37 studies evaluating risk factors associated with SARS-CoV-2 infection in health workers. Highlights include:

- SARS-CoV-2 infections occurred among health workers in various roles (clinical or non-clinical) and departments/settings (including outpatient and non-COVID-19 care settings).
- There was no consistent difference in risk of infection between job titles, including between nurses compared with physicians, which represented the most commonly reported health worker roles.

³ Adjusted HR 3.40, 95% CI 3.37–3.43

- There was no association found between sex or age and risk of SARS-CoV-2 infection or seropositivity in health workers.
- African-Americans and Hispanic health workers had an increased risk of SARS CoV-2 infection.
- Education and training in infection prevention and control were associated with decreased risk of SARS-CoV-2 infection in health workers.
- Certain exposures such as those involving intubations, other aerosol-generating procedures, direct patient contact, or contact with bodily secretions were found to be associated with increased infection risk compared with less intensive or direct exposure; though evidence was inconsistent, likely related to confounding factors such as those related to the availability, distribution, and use of PPE.
- Evidence on the association between health worker infection and use of individual PPE measures (masks, gloves, gown, eye protection) and hand hygiene was limited. However, most studies found that availability and appropriate use of PPE as recommended by local authorities was associated with decreased risk of SARS-CoV-2 infection. Evidence on the use of N95 or FFP2 respirators versus medical/surgical masks was inconclusive and limited to two inconsistent observational studies. Further information on the use of masks in health facilities can be found in the [interim guidance on mask use in the context of COVID-19](#).
- Three studies found that universal masking in health facilities was associated with decreased risk of SARS-CoV-2 infection in health workers.

A number of possible hypotheses may help to explain the observed trends in health worker infections. The higher proportion of health worker infections at the beginning of the pandemic in some countries may be due to the lack of preparedness to infectious disease outbreaks, of standard IPC precautions during care delivery, and reduced access to PPE, and overburdened health systems due to increased hospitalizations and limited health care capacities. Trends could also reflect different testing strategies prioritizing health workers over the general public. The subsequent decline in health worker infections could be a result of multiple interventions, including: i) training of health workers on IPC measures; ii) increased availability and appropriate use of personal protective equipment (PPE); iii) monitoring of IPC practices by occupational health and safety personnel; iv) improved clinical management based on improved knowledge about COVID-19, v) reduced bed capacity of COVID-19 patients in hospitals; vi) general reduction in community transmission with implementation of public health and social measures resulting in less pressure on hospital systems and hospitalizations; vii) increased SARS-CoV-2 testing capabilities; and, viii) increased knowledge of methods of transmission. Hence, it is impossible to determine from the available data how these interventions (individually or as a mix) contributed to the observed trends.

The WHO review of available studies found that observational studies provided important insights but had some methodological limitations. These limitations include potential recall bias, low or unclear participation rates, small sample sizes, and challenges in disentangling the effect of different measures, which were often implemented at the same time.

To bridge these gaps and improve the understanding of SARS-CoV-2 infection among health workers, WHO has developed a [standardized protocol](#) for COVID-19 surveillance among health workers that countries can use, and is leading an international multi-centre case-control [study](#) primarily aimed at identifying risk factors and settings of exposure. More than 140 sites in 28 countries have enrolled so far and recruitment is ongoing (for more information please contact: earlyinvestigations-2019-nCoV@who.int).

Additionally, to mitigate health workers' infections WHO has developed a [health workers' risk assessment and management of exposure to COVID-19 cases](#) and guidance on [Prevention, identification and management of health worker infection in the context of COVID-19](#).

WHO continues to support health workforce managers and policy makers with the December 2020 release of [Health workforce policy and management in the context of the COVID-19 pandemic response interim guidance](#), consolidating the evolving evidence on the design, management and preservation of the workforce necessary to respond to the COVID-19 pandemic and maintain essential health services.

Special Focus: Update on SARS-CoV-2 variants of concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available. Further information on the background of the variants of concern (VOC) is available from previously published [Disease Outbreak News](#) and in the last four publications of the [Weekly Epidemiological Updates](#).

WHO continues to work with partners to evaluate available evidence around transmissibility, severity, antibody neutralization capabilities and potential impacts on vaccines of specific mutations, variants of interest and variants of concern. Here we provide an update on the geographical distribution of three variants of concern as reported by countries, territories and areas (hereafter countries) as of 2 February 2021:

1. Variant VOC 202012/01, lineage B.1.1.7: Since our last update on 27 January, variant VOC 202012/01 has been detected in ten additional countries. As of 2 February, a total of 80 countries across all six WHO regions have reported either imported cases or community transmission of this variant (Figure 5).

Figure 5. Countries, territories and areas reporting SARS-CoV-2 VOC 202012/01 as of 2 February 2021

2. Variant 501Y.V2, lineage B.1.351: Since the last update on 27 January, 501Y.V2 has been reported from ten additional countries– now totaling 41 countries across four of the six WHO regions (Figure 6).

Figure 6. Countries, territories and areas reporting SARS-CoV-2 501Y.V2 as of 2 February 2021

3. Variant P.1, lineage B.1.1.28: Since our last update, variant P.1 has been reported in two additional countries. To date, this variant is reported in ten countries across four of the six WHO regions (Figure 7).

Figure 7. Countries, territories and areas reporting SARS-CoV-2 P.1 variant as of 2 February 2021

Last week, WHO held a multidisciplinary Global Transmission Discussion Seminar on SARS-CoV-2 variants and transmission. Participants from Brazil, Denmark, South Africa and the United Kingdom presented ongoing work aiming to understand transmission aspects of the variants of concern emerging in their countries, namely variants: P.1/P.2, cluster 5, 501Y.V2 and VOC202012/01, respectively. Initial analyses suggest that some variants may be more transmissible, possibly due to mutations that improve the virus's ability to bind to human cells, but available studies have found that the modes of transmission have not changed.

SARS-CoV-2 incidence and hospitalizations in a number of countries where VOC202012/01 and 501Y.V2 are circulating has started to decline in recent weeks, demonstrating the effectiveness of public health and social measures for controlling transmission of these variants.

The emergence of new variants has highlighted the importance for everyone to continue to comply with local and national public health and social measures, and to take simple precautions, such as physical distancing, wearing a mask, keeping rooms well ventilated, avoiding crowds, cleaning your hands, and coughing into a bent elbow or tissue (see also [Protect yourself and others from COVID-19](#)). It remains critical to increase diagnostic capacity and strategic genetic sequencing of SARS-CoV-2 where capacity allows, and continue to share sequence data internationally in a timely manner. Genetic sequencing should be considered for a subset of SARS-CoV-2 cases in each country, especially among outbreaks or clusters where transmission and/or severity may appear unusual. WHO has recently issued guidance for SARS-CoV-2 suggesting how to apply the use sequencing to monitor virus evolution in addition to epidemiological and virologic surveillance sequencing ([SARS-CoV-2 genomic sequencing for public health goals: Interim guidance](#); [Genomic sequencing of SARS-CoV-2: a guide to implementation for maximum impact on public health](#)).

Situation by WHO Region

African Region

In the past week, the African Region reported over 108 000 cases and just over 4600 deaths, a 27% decrease in cases and an 8% decrease in deaths respectively compared to the previous week. Cases have decreased for two consecutive weeks. The highest numbers of new cases were reported in South Africa (44 397 new cases; 74.9 new cases per 100 000 population; a 44% decrease), Nigeria (9955 new cases; 4.8 new cases per 100 000; a 15% decrease) and Zambia (8760 new cases; 47.7 new cases per 100 000; a 3% increase).

The countries reporting the highest number of new deaths in the past week were South Africa (3377 new deaths; 5.7 new deaths per 100 000; a 9% decrease), Zimbabwe (219 new deaths; 1.5 new deaths per 100 000; a 25% decrease) and Malawi (217 new deaths; 1.1 new deaths per 100 000; a 28% increase).

Region of the Americas

Over 1.8 million new cases and over 47 000 new deaths were reported in the Region of the Americas this week, a decrease of 11% and an increase of 4% respectively compared to the previous week. The highest numbers of new cases were reported from the United States of America (1 072 287 new cases; 324.0 new cases per 100 000 population; a 15% decrease), Brazil (364 593 new cases; 171.5 new cases per 100 000; a 1% increase) and Mexico (109 603 new cases; 85.0 new cases per 100 000; an 11% decrease).

The highest numbers of deaths were reported from the same countries, the United States of America (22 506 new deaths; 6.8 new deaths per 100 000; a 4% increase), Mexico (8965 new deaths; 7.0 new deaths per 100 000; a 4% increase) and Brazil (7423 new deaths; 3.5 new deaths per 100 000; a 6% increase).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 161 000 new cases, a decrease of 5% compared to last week. The region reported 3200 new deaths, a 9% increase. The three countries reporting the highest numbers of new cases continue to be the Islamic Republic of Iran (44 699 new cases, 53.2 new cases per 100 000 population, a 5% increase), Lebanon (22 326 new cases, 327.1 new cases per 100 000, a 19% decrease) and United Arab Emirates (26 285 new cases, 265.8 new cases per 100 000, 7% increase).

The highest numbers of new deaths were reported in Lebanon (751 new deaths, 11.0 new death per 100 000, an 81% increase), Iran (595 new deaths, 0.7 new death per 100 000 population, a 3% increase), and Tunisia (526 new deaths, 4.5 new death per 100 000, a 2% decrease).

European Region

The European Region reported over 1.2 million new cases and over 36 000 new deaths, a decrease of 18% and 8% respectively when compared to the previous week. The three countries reporting the highest numbers of new cases were the United Kingdom (178 629 new cases, 263.1 new cases per 100 000, a 31% decrease), France (141 092 new cases; 216.2 new cases per 100 000, a 2% increase) and the Russian Federation (131 039 new cases, 89.8 new cases per 100 000, a 13% decrease).

The highest numbers of deaths were reported from the United Kingdom (8242 new deaths; 12.1 new deaths per 100 000, a 6% decrease), Germany (5075 new deaths; 6.1 new deaths per 100 000, a 7% decrease) and the Russian Federation (3720 new deaths; 2.5 new deaths per 100 000, a 5% decrease).

South-East Asia Region

Following slow declines in the number of new cases in the South-East Asia Region in recent weeks, there was a plateau in newly reported cases (200 000 new cases, 3% increase from last week), and deaths (3000 new deaths, 0% change) this week. The three countries reporting the highest numbers of new cases and new deaths were India (91 650 new cases; 6.6 new cases per 100 000, a 5% decrease), Indonesia (88 839 new cases; 32.5 new cases per 100 000; a 10% increase) and Sri Lanka (5706 new cases; 26.6 new cases per 100 000; an 8% increase).

The three countries reporting the highest numbers of new deaths this week were Indonesia (2064 new deaths; 0.8 new deaths per 100 000, a 9% increase), India (935 new deaths; <0.1 new deaths per 100 000, a 12% decrease) and Bangladesh (108 new deaths; <0.1 new deaths per 100 000; a 10% decrease).

Western Pacific Region

The Western Pacific Region reported 72 000 new cases the past week, an 11% decrease compared the previous week, while a marked (21%) increase was seen in the number of new deaths, with over 1200 deaths reported this week. The three countries reporting the highest numbers of new cases in the region this week were Malaysia (29 206 new cases; 90.2 new cases per 100 000, a 15% decrease), Japan (26 081 new cases; 20.6 new cases per 100 000, a 32% decrease), and the Philippines (11 837 new cases; 10.8 new cases per 100 000, a 9% decrease).

The three countries reporting the highest numbers of new deaths this week were Japan (635 new deaths; 0.5 new deaths per 100 000, an 8% increase), the Philippines (479 new deaths; 0.4 new deaths per 100 000, an 11% increase) and Malaysia (79 new deaths; 0.2 new deaths per 100 000, a 56% increase).

Key Weekly Updates

WHO Director-General Dr Tedros remarks

On health workers and older people

"I leave you with the challenge I set at the beginning of the week: together, we must ensure that vaccination of health workers and older people is underway in all countries within the first 100 days of this year." [Closing remarks at 148th session of the Executive Board](#)

On vaccine equity

"Vaccine nationalism is self-defeating and inefficient, leaving the world's poorest and most vulnerable people at risk." The Director-General recommended three urgent actions: "First, prompt and equitable dose sharing is critical if we are to overcome this pandemic. Second, we need support to close the funding gap of 26 billion US dollars for the ACT Accelerator this year, including 7.8 billion dollars for COVAX. If fully funded, the ACT Accelerator would return up to 166 US dollars for every dollar invested. And third, even as we work to end the pandemic, we must learn the lessons it is teaching us." [NORAD Conference 2021, panel: Vaccine nationalism and global distribution](#) and [Closing remarks at 148th session of the Executive Board](#)

Therapeutics and vaccines

"We have identified dexamethasone to treat severe disease, which is being stockpiled for use in low and lower-middle income countries.

And the development and approval of safe and effective vaccines less than a year after the emergence of this new virus is a stunning scientific achievement. It gives us all a much-needed source of hope." [Debate on the report "COVID-19 vaccines: ethical, legal and practical considerations](#)

Moderna vaccine

[The Moderna COVID-19 \(mRNA-1273\) vaccine: what you need to know](#)

[Interim recommendations for use of the Moderna mRNA-1273 vaccine against COVID-19](#)

Testing

Recommendations and advice for the public

- [Protect yourself](#)
- [Questions and answers](#)
- [Travel advice](#)
- [EPI-WIN](#): tailored information for individuals, organizations and communities

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
 - Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g., laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
 - Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
 - Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
 - Pending: transmission classification has not been reported to WHO.
- ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 24 January 2021, 10 am CET

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Globally, 4.1 million new cases were reported in the past week, a decline of 15% from the previous week and the second week of decline after global case incidence peaked in the first week of January 2021 (Figure 1). This downward trend is largely attributed to relative reductions in case incidence in several countries that have contributed the highest numbers in recent months, but hides continued upward trends in other countries in the same regions. The ongoing and prolonged high rates of new infections continues to strain health systems in many countries around the world. All regions reported a decline in new cases except the Western Pacific Region which reported a similar incidence to last week (Table 1). The largest decrease in new cases was reported in the European Region (by 20%) followed by the African Region (decrease of 16%). The Americas and Europe reported 86% of all new cases globally in the past week.

During the same period, around 96 000 deaths have been reported – a similar number reported as last week. The Americas and Eastern Mediterranean region reported an increase in new deaths by 4% and 3% respectively, whereas Europe, South-East Asia and Western Pacific regions showed a decrease in new deaths compared to last week. No change in new deaths was seen for the African region.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 24 January 2021**

**See [data](#), [table](#) and [figure notes](#)

In the past week, the five countries reporting the highest number of new cases continue to be the United States of America (1 259 902 cases, a 20% decrease), Brazil (360 428 cases, a 5% decrease), the United Kingdom of Great Britain and Northern Ireland (260 098 cases, a 24% decrease), the Russian Federation (151 191 cases, a 9% decrease) and France (138 288 cases, a 10% increase).

In this edition of the COVID-19 Weekly Epidemiological Update, special focus updates are provided on:

- [Solidarity II forum and use of international standards for sero-epidemiology surveys](#)
- [SARS-CoV-2 variants of concern](#)
- Additional Region-specific information: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#)
- [Key Weekly Updates](#)

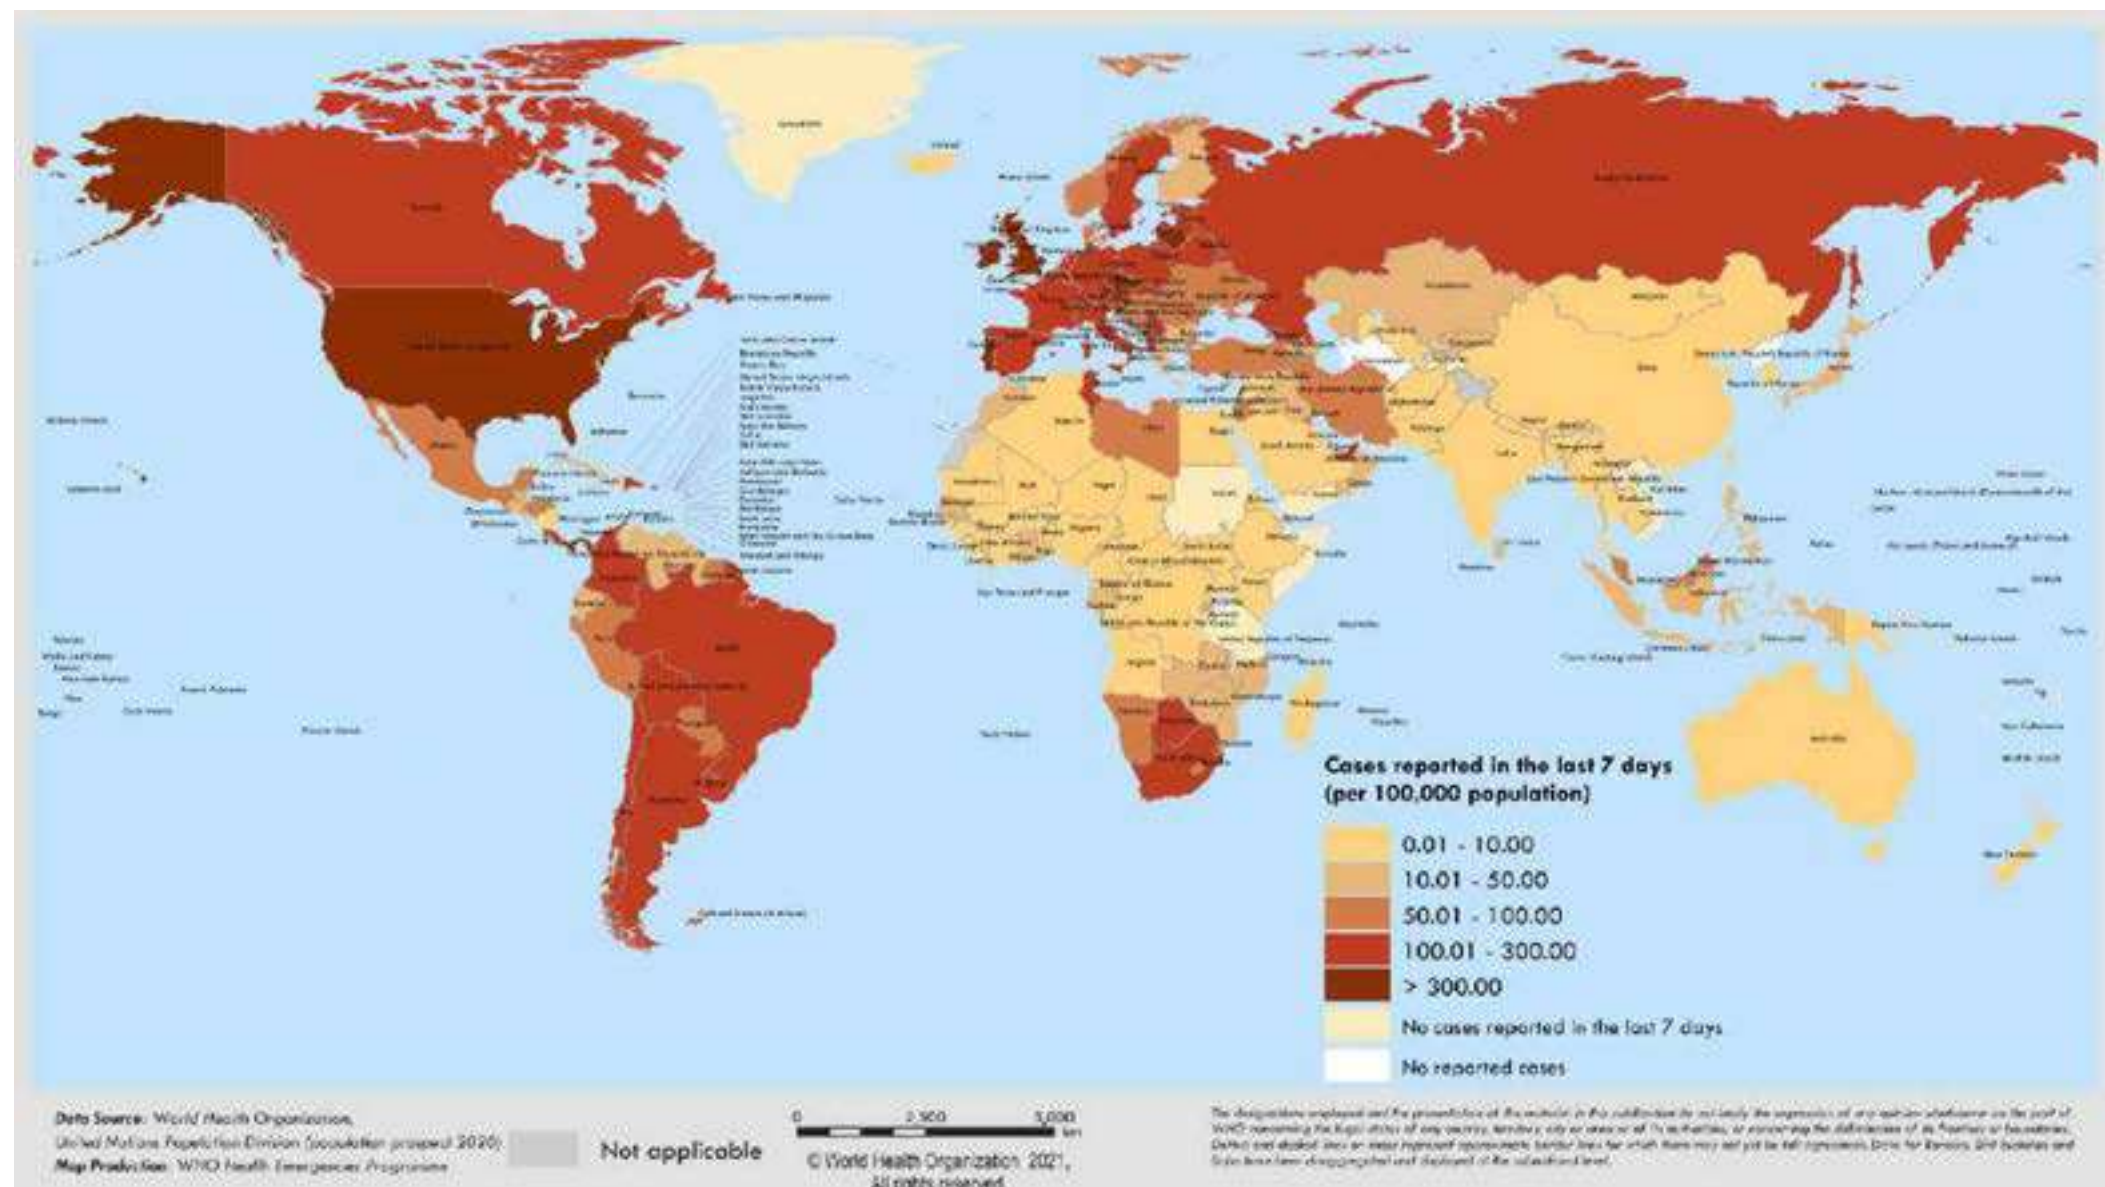

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 24 January 2021**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days *	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days *	Cumulative deaths (%)
Americas	2 127 479 (52%)	-14%	43 456 972 (44%)	45 349 (47%)	4%	999 894 (47%)
Europe	1 382 460 (34%)	-20%	32 848 998 (33%)	38 349 (40%)	-1%	706 293 (33%)
South-East Asia	194 166 (5%)	-5%	12 656 504 (13%)	3 253 (3%)	-5%	194 449 (9%)
Eastern Mediterranean	170 422 (4%)	-7%	5 507 649 (6%)	2 980 (3%)	3%	130 901 (6%)
Africa	148 953 (4%)	-16%	2 462 083 (3%)	4 997 (5%)	0%	57 902 (3%)
Western Pacific	81 467 (2%)	0%	1 347 893 (1%)	1 063 (1%)	-5%	23 307 (1%)
Global	4 104 947 (100%)	-15%	98 280 844 (100%)	95 991 (100%)	1%	2 112 759 (100%)

*Percent change in the number of newly confirmed cases/deaths in past seven days, compared to seven days prior. Regional percentages rounded to the nearest whole number, global totals may not equal 100%.

**See [data](#), [table](#) and [figure](#) notes.

Figure 2. COVID-19 cases per 100 000 population reported in the last seven days by countries, territories and areas, 18 January through 24 January 2021**

Special Focus: Solidarity II forum and use of international standards for sero-epidemiology surveys

Solidarity II is a sero-epidemiological international forum

[Solidarity II](#) is a global collaborative forum that promotes the implementation of serological surveys for estimating the exposure to SARS-CoV-2 in the population. The Solidarity II network facilitates discussions between public health agencies and academic institutions with three main objectives: 1) sharing cutting edge scientific findings, 2) identifying and bridging research gaps, and 3) creating collaborations to progress the research of serological epidemiology of SARS-CoV-2.

Why use a common language across serological assays?

Serology is the study of serum and other fluids in the body, which is used to ascertain if antibodies are present. Serological assays are also used to determine the level of antibody response to SARS-CoV-2. A WHO Q&A on serology is available [here](#). The availability of an International Standard for antibodies facilitates the standardization of SARS-CoV-2 serological methods, and allows for comparison and harmonisation of data sets across laboratories. The readout from serology assays can be expressed in different and non-comparable units, including unit/mL, titer or ng/mL, and should be calibrated to international units to allow comparisons.

WHO Working Assay Group meeting on the calibration of serological assays with the WHO IS

On 20 January 2021, 90 participants from the Solidarity II forum, from 34 countries, joined SARS-CoV-2 vaccine developers at the Working Assay Group meeting on the calibration of serological assays with the WHO International Standard anti-SARS-CoV-2 Immunoglobulin (WHO IS). Participants included national research institutes, academic research groups as well as clinical laboratories. This meeting was the first webinar aimed at standardizing the practice of SARS-CoV-2 serological assays. During this meeting, WHO presented the outcome from the [73rd meeting of the WHO Expert Committee on Biological Standardization \(ECBS\)](#). More information can be found in the WHO guidance on [Calibration to WHO International Standards](#).

How to order the WHO International Standard anti-SARS-CoV-2 Immunoglobulin (WHO IS)

The WHO IS is now available and can be ordered directly from the [NIBSC website](#). The Solidarity II forum is offering financial support to low and middle income country (LMIC) research groups to acquire this material as well as technical support for the implementation of the calibration protocol. Working/secondary serological reagents will also be soon available through the Solidarity II network.

For more information about WHO's work on SARS-CoV-2 serology, please see the website on [Serology and Early Investigation Protocols](#) or contact solidarity2@who.int.

Special Focus: Update on SARS-CoV-2 variants of concern

WHO, in collaboration with national authorities, institutions and researchers, continues to monitor the public health events associated with SARS-CoV-2 variants and provides updates as new information becomes available. Further information on the background of the variants of concern (VOC) is available from previously published [Disease Outbreak News](#) and in the last three publications of the [Weekly Epidemiological Updates](#).

WHO is working with partners to evaluate available evidence around transmissibility, severity, antibody neutralization capabilities and potential impacts on vaccines of specific mutations, variants of interest and variants of concern. Here we provide an update on ongoing studies, as well as the geographical distribution of three variants of concern as reported by countries, territories and areas (hereafter countries) as of 25 January 2021:

1. Variant VOC 202012/01, lineage B.1.1.7: Since our last update on 19 January, variant VOC 202012/01 has been detected in ten additional countries. As of 25 January, a total of 70 countries across all six WHO regions have reported either imported cases or community transmission of this variant (Figure 3). Local transmission has been reported in several other European countries.

Figure 3. Countries, territories and areas reporting SARS-CoV-2 VOC 202012/01 as of 25 January 2021

In the United Kingdom of Great Britain and Northern Ireland, where this variant was initially identified, variant VOC 202012/01 has shown to have increased transmissibility compared to previously circulating variants. The United Kingdom has also recently shared results from studies suggesting that there is some evidence of an increase in disease severity; however, results are preliminary, and more analyses are required to further corroborate these findings (1).

In the United Kingdom, COVID-19 case incidence increased week-on-week since early December 2020, peaking in early January 2021. From 11 January through 24 January, a decreasing trend has been observed, following the implementation of stringent public health and social measures. Similar declines in incidence have also been reported in Denmark, Ireland and the Netherlands, where local transmission of VOC 202012/01 has been reported.

neutralization on clinical efficacy. Out of an abundance of caution, Moderna is investigating the potential use of an additional booster dose to increase neutralizing titres against emerging variants and beginning to evaluate an emerging variant booster candidate vaccine (4).

3. Variant P.1, lineage B.1.1.28: Since our last update, variant P.1 has been reported in six additional countries. To date, this variant is reported in eight countries (Figure 5). In Brazil, where the variant was initially identified in addition to detection in a group of travellers from Brazil to Japan, the number of new weekly cases in the past two weeks are reported at higher levels compared to that of September to November 2020, and new weekly deaths have increased since early November 2020. The highest weekly cases since the start of the pandemic was reported in the week commencing 11 January 2021. Based on the preliminary investigations conducted in Manaus, Amazonas State, there has been an increase in the proportion of cases sequenced as variant P.1, from 52.2% (35/67) in December 2020 to 85.4% (41/48) in January 2021, highlighting ongoing local transmission of this variant and, given the mutations documented, raising similar concerns for potential increases in transmissibility or propensity for re-infection (10). Further studies are needed to assess if there are changes in transmissibility, severity or antibody neutralizing activity as a result of these new variants.

Figure 5. Countries, territories and areas reporting SARS-CoV-2 P.1 variant as of 25 January 2021

The emergence of new variants has underscored the importance for everyone, including those previously infected or vaccinated, to strictly adhere to public health and social measures. They also highlight the importance of increasing diagnostic capacity and systematic sequencing of SARS-CoV-2 where capacity allows, as well as the timely sharing of sequence data internationally. Systematic sequencing should be considered for a subset of incoming travellers, as well as community-based samples to ascertain the existence and extent of local transmission. Virus sequencing should be performed in all breakthrough disease following vaccination, in addition to population-based vaccine effectiveness studies. Global surveillance on virus evolution should continue to inform adjustments to public health and social measures.

Situation by WHO Region

African Region

In the past week, the African Region reported over 148 000 cases and just under 5000 deaths, a 16% decrease in cases and similar number of deaths compared to the previous week. This was the first time since mid-September 2020 that weekly cases decreased. The highest numbers of new cases were reported in South Africa (79 180 new cases; 133.5 new cases per 100 000 population; a 29% decrease), Nigeria (11 659 new cases; 5.7 new cases per 100 000; a 2% increase) and Zambia (8518 new cases; 46.3 new cases per 100 000; a 10% decrease).

The countries reporting the highest number of new deaths in the past week were South Africa (3723 new deaths; 6.3 new deaths per 100 000; a 8% decrease), Zimbabwe (291 new deaths; 2.0 new deaths per 100 000; a 35% decrease) and Malawi (170 new deaths; 0.9 new deaths per 100 000; a 113% increase).

Region of the Americas

Over 2.1 million new cases and over 45 000 new deaths were reported in the Region of the Americas this week, a decrease of 14% and an increase of 4% respectively compared to the previous week. The highest numbers of new cases were reported from the United States of America (1 259 902 new cases; 380.6 new cases per 100 000 population; a 20% decrease), Brazil (360 428 new cases; 169.6 new cases per 100 000; a 5% decrease) and Mexico (122 555 new cases; 95.1 new cases per 100 000; a 20% increase).

The highest numbers of deaths were reported from the same countries, the United States of America (21 583 new deaths; 6.5 new deaths per 100 000; a 7% decrease), Mexico (8592 new deaths; 6.7 new deaths per 100 000; a 24% increase) and Brazil (6997 new deaths; 3.3 new deaths per 100 000; a 3% increase).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 170 000 new cases, a decrease of 7% compared to last week. The region reported 2980 new deaths, an increase of 3%, the second consecutive weekly increase following a sustained decrease in deaths from 23 November 2020 through the week of 11 January 2021. The three countries reporting the highest numbers of new cases continue to be Iran (42 637 new cases, 50.8 new cases per 100 000 population, a 3% decrease), Lebanon (27 429 new cases, 401.9 new cases per 100 000, 18% decrease) and United Arab Emirates (24 568 new cases, 248.4 new cases per 100 000, 11 % increase). These three countries accounted for almost half (55%) of the new weekly cases in the Region.

The highest numbers of new deaths were reported in Iran (577 new deaths, 0.7 new death per 100 000 population, 7% decrease) followed by Tunisia (538 new deaths, 4.6 new death per 100 000, 16% increase) and Lebanon (414 new deaths, 6.1 new death per 100 000, a 50% increase). These countries accounted for almost 51% of deaths reported in the Region.

European Region

The European Region reported over 1.3 million new cases and over 38 000 new deaths, a decrease of 20% and 1% respectively when compared to the previous week. The three countries reporting the highest numbers of new cases were the United Kingdom (260 098 new cases; 383.1 new cases per 100 000, 24% decrease), the Russian Federation (151 191 new cases, 103.6 new cases per 100 000, 9% decrease) and France (138 288 new cases, 211.9 new cases per 100 000, 10% increase). These three countries accounted for almost 40% of all cases reported in the region.

The highest numbers of deaths were reported from the United Kingdom (8739 new deaths; 12.9 new deaths per 100 000, a 13% increase), Germany (5451 new deaths; 6.5 new deaths per 100 000, a 10% decrease) and the Russian Federation (3896 new deaths; 2.7 new deaths per 100 000, a 5% increase).

South-East Asia Region

The South-East Asia Region reported a decrease in cases and deaths compared to the previous week following a 3- week plateau in new case and death reports. Just over 194 000 new cases and over 3000 new deaths were reported in the past week, a 5% decrease in both cases and deaths, compared to the previous week. The three countries reporting the highest numbers of new cases and new deaths were India (96 548 new cases; 7 new cases per 100 000, a 10% decrease), Indonesia (80 832 new cases; 29.6 new cases per 100 000; a 3% increase) and Sri Lanka (5274 new cases; 24.6 new cases per 100 000; an 18% increase). The three countries reporting the highest numbers of new deaths this week were Indonesia (1897 new deaths; 0.7 new deaths per 100 000, a 4% increase), India (1065 new deaths; 0.1 new deaths per 100 000, a 17% decrease) and Bangladesh (120 new deaths; 0.1 new deaths per 100 000; a 6% decrease).

Western Pacific Region

The Western Pacific Region reported a similar number of new cases (over 81 000 cases) and decrease in new deaths by 5% (over 1000) in the past week compared to the previous week. The three countries reporting the highest numbers of new cases this week were Japan (38 365 new cases; 30.3 new cases per 100 000, a 8% decrease), Malaysia (25 360 new cases; 78.4 new cases per 100 000, a 18% increase) and the Philippines (12 988 new cases; 11.9 new cases per 100 000, a 1% increase).

The three countries reporting the highest numbers of new deaths this week were Japan (573 new deaths; 0.5 new deaths per 100 000, a 27% increase), the Philippines (306 new deaths; 0.3 new deaths per 100 000, a 37% decrease) and the Republic of Korea (100 new deaths; 0.2 new deaths per 100 000, a 19% decrease).

Table 2. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region, as of 24 January 2021**

Reporting Country/Territory/Area ⁱ	New cases in last 7 days	Cumulative cases	Cumulative cases per 100 thousand population	New deaths in last 7 days	Cumulative deaths	Cumulative deaths per 100 thousand population	Transmission classification ⁱⁱ

Key Weekly Updates

WHO Director-General Dr Tedros remarks

“Several lessons are already staring us in the face...First, <the importance of> preparedness and response, second the health of humans, animals and the planet are intimately intertwined, and third, the world needs a strong WHO.” [Opening remarks at 148th session of the Executive Board](#)

“The development and approval of safe and effective vaccines less than a year after the emergence of a new virus is a stunning scientific achievement, and a much-needed source of hope.” [Opening remarks at the extraordinary meeting of the Strategic Advisory Group of Experts \(SAGE\) on Immunization](#)

“Two new studies show that <if we don’t deliver equitable access to vaccines> it wouldn’t just be a moral failure, it would be an economic failure.” [Opening remarks at the media briefing on COVID-19 – 25 January 2021](#)

COVAX on track to deliver 2 billion vaccine doses

[COVAX on track to deliver at least 2 billion vaccine doses by the end of the year, including at least 1.3 billion doses to 92 lower income economies](#)

Vaccine safety for frail, elderly patients

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps

represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 17 January 2021, 10 am CET

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Globally, 4.7 million new cases were reported in the past week, a decline of 6% from last week (Figure 1). At the same time, the number of new deaths has climbed to a record high at 93 000, a 9% increase from last week. Over 2 million people have now lost their lives to COVID-19. The Americas, Europe, and South-East Asia regions showed declines in new cases, with Europe showing a 15% decline and the Americas and South-East Asia regions showing more moderate declines of 2% and 1% respectively (Table 1). On the other hand, the Eastern Mediterranean, African, and Western Pacific regions reported increases in new cases, with the Western Pacific showing the largest increase (14%). All regions reported increases in new deaths; case incidence continues to be one of the primary drivers of mortality – where increases in the number of COVID-19 related hospitalizations and deaths follow large numbers of cases after a short time lag.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 17 January 2021**

In the past week, the five countries reporting the highest number of cases were the United States of America (1 583 237 cases, an 11% decrease), Brazil (379 784 cases, a 21% increase), the United Kingdom of Great Britain and Northern Ireland (339 952 cases, a 19% decrease), the Russian Federation (166 255 cases, 1% increase) and France (125 279 cases, a 2% increase).

In this edition of the COVID-19 Weekly Epidemiological Update, special focus updates are provided on:

Special Focus: Children, COVID-19, and transmission in schools

One of the most concerning questions has been the extent to which COVID-19 affects children and adolescents and the role of schools in community transmission. As WHO Director-General Dr Tedros said in a press conference, “understanding how COVID-19 affects children has been a priority issue. We all want to see children back at school and we all want to make sure schools are the safe and supportive learning environments they should be.”¹ Research is ongoing into the factors that may put children and adolescents at risk, long-term health effects in those who have been infected, and importantly the impact of new variants of SARS-CoV-2. Here we present a number of research findings learned in 2020.

- Of all COVID-19 cases reported by countries, children and adolescents under 18 have represented around 8% of cases in 2020, despite comprising 29% of the global population. This may be due to the under reporting of mild and asymptomatic infections, which are more likely among children and adolescents.
- Children are also much less likely than adults to be hospitalized or have fatal outcomes.² Approximately 0.2% of deaths were reported in people under the age of 20 years.³
- Evidence suggests that adolescents appear to transmit the virus as often as adults, whereas children under 10 years seem to be less susceptible and less infectious than older children and adolescents⁴. This is supported by the higher frequency of outbreaks reported in secondary/high schools compared to in primary/elementary schools⁵
- Large-scale community-based studies in the UK have showed higher levels of acute infection among adolescents and young adults compared to other age groups, further supporting differences in transmission patterns and susceptibility between primary and secondary-school aged children^{6,7}.
- A study⁸ in Norway from August to November 2020 found low levels of child-to-child and child-to-adult transmission in primary schools (children aged 5-13 years) that had infection prevention and control measures in place. Viral load studies suggest that children with symptoms carry as much virus in the nose, mouth and throat as adults, but for shorter periods with peak respiratory viral load early after symptom onset, followed by a rapid decline after the first week of illness.
- National surveillance data from the United Kingdom found that school staff are at lower risk of infection in school settings when compared to the general adult population. Another study among 57 000 caregivers at childcare facilities in the United States of America, found that there was no increased risk of infection for the caregivers.⁹
- Several studies and reviews have shown that school re-openings have not been associated with significant increases in community transmission.^{10,11,12,13} The return to school of many children in mid-August, following periods of lower community transmission in many countries, does not appear to have contributed toward the

¹³ Yoon et al., 2020 (<https://www.medrxiv.org/content/10.1101/2020.08.03.20165589v1>)

risers seen in October. A United Kingdom government report¹⁴ found that when schools reopened in England and Wales in the summer, the infection rates among students did not increase over the existing population rate. A study in the Republic of Korea¹² found that there was not an increase in COVID-19 cases in the two months following the resumption of classes in May, and that in most COVID-19 cases in children, the infection had been acquired from family members outside of school.

- Following the detection of new SARS-CoV-2 variants of concern (VOC), further investigations are underway to fully assess each variant and potential impacts on COVID-19 age and sex distributions. Investigations in the United Kingdom suggest that the age and sex profile of VOC 202012/01 cases are similar to other SARS-CoV-2 viruses.¹⁵
- Impacts of school closures on children and adolescents:
 - The longer vulnerable children are out of school, the less likely they are to return.
 - Children from the poorest households are almost five times more likely to be out of primary school than those from the richest. Being out of school increases the risk of teenage pregnancy, sexual exploitation, child marriage, violence and other threats.¹⁶
 - Prolonged closures disrupt essential school-based services such as immunization, school feeding, and mental health and psychosocial support, and disrupt the important roles school play in child protection.¹⁷
 - Closures also cause stress and anxiety due to the loss of peer interaction and disrupted routines. These negative impacts are significantly higher for vulnerable children, such as those living in countries affected by conflict and other protracted crises, migrants, refugees and the forcibly displaced, minorities, children living with disabilities, and children in institutions.¹⁸
 - School closures affect children negatively in many ways besides their education, including equity, child health (both physical and mental health) and development and can affect the ability of parents to work, introducing other risks.^{19,20}

Audrey Azoulay, UNESCO Director-General, has warned that “The longer schools remain closed, the more damaging the consequences, especially for children from more disadvantaged backgrounds ... therefore, supporting safe schools must be a priority for us all”.²¹ Henrietta Fore, the United Nations Children’s Fund (UNICEF) Executive Director stated, “As we enter the second year of the COVID-19 pandemic, and as cases continue to soar around the world, no effort should be spared to keep schools open or prioritize them in reopening plans....closing schools must be a measure of last resort, after all other options have been considered.”²²

Based on available information, a number of preliminary conclusions and recommendations have been made:

- Transmission occurring in communities can be reflected in school settings: when community transmission is low and when appropriate mitigation measures are applied, schools are unlikely to be the main drivers of COVID-19

transmission. However, where there is community transmission and/or the number of new cases is rising, schools, and particularly secondary schools, may play a substantial role in community transmission. As such, WHO continues to advise a comprehensive approach to reduce transmission, including early detection and isolation of cases as well as contact tracing and supported quarantine, along with other risk mitigation public health measures to reduce exposure and spread.

- WHO and partners have issued guidance on the safe operation of schools during the COVID-19 pandemic (see key resources below). Schools should have outbreak prevention and management plans ready, including control measures to protect staff and individuals at high risk. Measures include the need for adequate ventilation, hygiene practices (such as hand cleaning, cleaning of surfaces and items), mask use (12 years and older should wear a mask under the same conditions as adults and teacher and support staff should wear masks when they cannot guarantee at least a 1-metre distance from others where there is widespread transmission in the area), physical distancing (such as by limiting the number of students per class, alternating shifts, limiting mixing of classes), and frequent communication with parents, students, teachers and staff (such as asking parents to report any cases of COVID-19 in the household, posting signs in visible locations).
- Strong infection prevention and control measures are necessary in all schools and may need to be applied differently based on the age of the students (e.g. secondary/high schools and older students compared to primary/elementary schools and younger students). In particular, all students should be reminded to limit their risk of exposure outside educational settings by avoiding high risk environments, including crowded, close-contact and poorly ventilated spaces.
- School teachers and staff need to remain vigilant to prevent exposure outside the school, where they can be infected.
- Where a student or staff tests positive for SARS-CoV-2, appropriate actions must be taken, including notifying health officials, staff and families, cooperating closely with local health authorities, quarantine, identifying and notifying close contacts and advising them to stay home for 14 days, and disinfecting school areas.
- Considerations to decide to close, partially close or reopen schools should be guided by a risk-based approach to maximize the educational and health benefit for students, teachers, staff, and the wider community, and help prevent transmission of SARS-CoV-2 in the community. School closure should be implemented as a last resort, be temporary and only at a local level in areas with intense transmission.
- Where schools are fully or partially closed, opportunities for remote learning should be instituted, school-based health services, immunization, meals and support services should be maintained, and opportunities for psychosocial and mental health support enhanced.
- The time during which schools are physically closed should be used to put in place measures to prevent and respond to transmission when schools reopen.
- Health and education authorities should continue to monitor guidance based on new information and research, particularly with respect to the appearance of new and possibly more transmissible variants of SARS-CoV-2.

WHO thanks the participation of UNICEF in this special focus.

Special Focus: Update on SARS-CoV-2 variants of concern

WHO, in collaboration with national authorities, institutions and researchers, is closely monitoring the public health events associated with SARS-CoV-2 variants and will continue providing updates as new information becomes available. This includes routine assessment of SARS-CoV-2 variants to establish if they have altered transmissibility, clinical presentation and severity, or if they may respond differently to countermeasures, including diagnostics, therapeutics and vaccines. Further information on the background of variants of concern (VOC) is available in [Disease Outbreak News](#) and the Weekly Epidemiological Updates published on [5 January 2021](#) and [11 January 2021](#).

Since the last update on 12 January, VOC 202012/01 has been detected in 10 additional countries, territories and areas (hereafter countries). To date, 60 countries across all six WHO regions have reported either imported cases or community transmission of this variant (Figure 3). Several reports of ongoing [studies evaluating transmission and severity have been made available by Public Health England](#). Concurrently, variant 501Y.V2 has been reported from three additional countries – now totaling 23 countries across four of the six WHO regions.

Figure 3. Countries, territories and areas reporting SARS-CoV-2 VOC 202012/01 and SARS-CoV-2 501Y.V2 variant as of 19 January 2021

Since our last update, a new variant (named the P.1 variant) has been reported from Brazil (Manaus, Amazonas State), which belongs to Nextstrain clade 20B, GISAID clade GR, and Pangolin lineage B.1.1.28. This variant includes mutations N501Y, E484K, K417T, and deletion in ORF1b (del11288-11296) in the spike protein. In addition to the P.1 variant, another variant within the lineage B.1.1.28 with the E484K mutation (but none of the other mutations) has been reported from Brazil. There is currently little available information to assess if there are changes in transmissibility or severity as a result of these new variants; however, given similar amino acid changes observed in VOC 202012/01 and 501Y.V2, which have shown increased transmissibility and potential impacts on antibody neutralization, further investigations are needed and are underway.

On 14 January, WHO Director-General convened the sixth meeting of the [Emergency Committee on COVID-19](#), which included discussions on the impact of the emerging variants of SARS-CoV-2 and additional travel restrictions that many countries are imposing. The WHO secretariat presented a Risk Monitoring Framework to identify, monitor and assess SARS-CoV-2 mutations, variants of interest and variants of concern. The Emergency Committee supported the [call for a global effort](#) to sequence and share data to monitor the virus evolution and collaborate scientifically to increase global understanding of variants and their effects on vaccine, therapeutics and diagnostic efficacy. The Committee advised WHO to develop a standardized nomenclature and definitions of SARS-CoV-2 virus variants that are geographically neutral, an area WHO has already begun work in.

On 12 January and 15 January, WHO convened two global virtual meetings of scientific experts and partners, to identify and discuss critical knowledge gaps and research priorities for [emerging variants of SARS-CoV-2](#), and [vaccines developed for SARS-CoV-2](#). The participants of both meetings emphasized the importance of coordinated research to detect and understand early the potential impact of emerging variants on diagnostics, treatments, the efficacy of vaccines, the impact of vaccines on transmission of infection, and the need to develop the next generation of vaccine platforms. WHO will work to ensure that critical research is coordinated across all partners. The meeting concluded with agreement to establish a WHO-hosted platform for global sharing and coordination of emerging vaccine research information on efficacy and safety. The forum would enable scientists to share and discuss unpublished and published data and research protocols to further our collective understanding of SARS-CoV-2 vaccines.

Situation by WHO Region

African Region

In the past week, the African Region reported over 177 000 cases and 5000 deaths, a 1% increase in cases and 16% increase in deaths compared to the previous week. Cases in the Region continue to increase since mid-September 2020; however, the increase this week has been slight when compared to steeper increases in recent months. The highest numbers of new cases were reported in South Africa (111 483 new cases; 188 new cases per 100 000 population; a 11% decrease), Nigeria (11 465 new cases; 5.6 new cases per 100 000; a 38% increase) and Zambia (9507 new cases; 51.7 new cases per 100 000; a 78% increase).

The countries reporting the highest number of new deaths in the past week were South Africa (4027 new deaths; 6.8 new deaths per 100 000; a 10% increase), Zimbabwe (200 new deaths; 1.3 new deaths per 100 000; an 89% increase) and Malawi (80 new deaths; 0.4 new deaths per 100 000; a 186% increase).

Region of the Americas

Over 2.4 million new cases and over 43 000 new deaths were reported in the Region of the Americas this week, a decrease of 2% and an increase of 15% respectively compared to the previous week. For the past four weeks, the highest numbers of new cases continue to be reported from the United States of America (1 583 237 new cases; 478.3 new cases per 100 000 population; a 11% decrease), Brazil (379 784 new cases; 178.7 new cases per 100 000; a 21% increase) and Colombia (114 611 new cases; 225.2 new cases per 100 000; a 14% increase).

The highest numbers of deaths were reported from the United States of America (23 198 new deaths; 7.0 new deaths per 100 000; a 12% increase), Mexico (6953 new deaths; 5.4 new deaths per 100 000; a 25% increase) and Brazil (6786 new deaths; 3.2 new deaths per 100 000; a 12% increase).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 183 000 new cases, an increase of 7% compared to last week. The region reported 2846 new deaths, an increase of 2% after a sustained decrease in deaths from 23 November 2020 through the week of 11 January 2021. The three countries reporting the highest numbers of new cases continue to be Iran (43 957 new cases, 52.3 new cases per 100 000 population, a 2% increase), Lebanon (33 605 new cases, 492.3 new cases per 100 000, 15% increase) and United Arab Emirates (22 106 new cases, 223.5 new cases per 100 000, 38 % increase). These three countries accounted for almost half (54%) of the new weekly cases in the Region.

The highest numbers of new deaths were reported in Iran (617 new deaths, 0.7 new death per 100 000 population, 7% decrease) followed by Tunisia (463 new deaths, 3.9 new death per 100 000, 19% increase) and Egypt (385 new deaths, 0.4 new death per 100 000, a 4 % decrease). These countries accounted for almost 52% of deaths reported in the Region.

European Region

The European Region continues to report a substantial number of cases with over 1.6 million new cases and over 37 000 new deaths, a decrease of 15% and an increase of 2% respectively when compared to the previous week. The three countries reporting the highest numbers of new cases were the United Kingdom (339 952 new cases; 500.8 new cases per 100 000, 19% decrease), the Russian Federation (166 255 new cases, 113.9 new cases per 100 000, 1% increase) and France (125 279 new cases, 191.9 new cases per 100 000, 2% increase). These three countries accounted for almost 40% of all cases reported in the region with the United Kingdom accounting for 21% of all new cases.

The highest numbers of deaths were reported from the United Kingdom (7722 new deaths; 11.4 new deaths per 100 000, 23% increase), Germany (6076 new deaths; 7.3 new deaths per 100 000, similar to the previous week) and the Russian Federation (3729 new deaths; 2.6 new deaths per 100 000, a 12% increase).

South-East Asia Region

The South-East Asia Region continues to report falling numbers of new cases and deaths, a decline observed since September 2020. Just over 200 000 new cases and over 3400 new deaths were reported in the past week, a 1% decrease and 4% increase respectively, compared to the previous week. The three countries reporting the highest numbers of new cases and new deaths were India (107 701 new cases; 7.8 new cases per 100 000, a 15% decrease), Indonesia (78 256 new cases; 28.6 new cases per 100 000; a 31% increase) and Bangladesh (5681 new cases; 3.4 new cases per 100 000; an 8% decrease).

The three countries reporting the highest numbers of new deaths this week were India (1275 new deaths; 0.1 new death per 100 000, a 18% decrease), Indonesia (1820 new deaths; 0.7 new death per 100 000, a 31% decrease) and Bangladesh (127 new deaths; 0.1 new death per 100 000; a 19% decrease).

Western Pacific Region

The Western Pacific Region reported an increase in the number of new cases by 14% (over 81 000) and new deaths by 35% (over 1100) in the past week compared to the previous week. The upward trend in new weekly cases and deaths has continued since October 2020. The three countries reporting the highest numbers of new cases this week were Japan (41 521 new cases; 32.8 new cases per 100 000, a 4% increase), Malaysia (21 536 new cases; 66.5 new cases per 100 000, a 33% increase) and the Philippines (12 894 new cases; 11.8 new cases per 100 000, a 45% increase).

The three countries reporting the highest numbers of new deaths this week were the Philippines (486 new deaths; 0.4 new deaths per 100 000, a 235% increase), Japan (450 new deaths; 0.4 new deaths per 100 000, similar to previous week) and the Republic of Korea (124 new deaths; 0.2 new deaths per 100 000, a 24% decrease).

Key Weekly Updates

1. WHO is encouraging all countries to fulfil their pledges to COVAX. WHO is calling on all countries to start vaccinating health workers and those at high risk of developing severe disease or death in the next 100 days.
2. 13 January 2021 marks the one-year anniversary of WHO publishing the first protocol for developing PCR assays for diagnosing the new coronavirus, less than two weeks after the first cases were reported. The rapid isolation and sequencing of the virus laid the platform for the development of vaccines, which are now being rolled out globally.
3. An international team of scientists is in China to engage in and review scientific research with their Chinese counterparts on the origins of the virus.
4. As new virus variants have been reported, WHO calls on all countries to increase the systematic sequencing of the virus to supplement ongoing surveillance, monitoring and testing efforts.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see [covid19.who.int](#) for the most up-to-date data.

Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

In the past week, the five countries reporting the highest number of cases were the United States of America (with 1 786 773 cases, a 35% increase), the United Kingdom of Great Britain and Northern Ireland (417 620 cases, a 22% increase), Brazil (313 130 cases, a 24% increase), the Russian Federation (165 167 cases, continuing last week's decrease with an 12% decrease) and Germany (142 861 cases, reversing last week's decrease with a 15% increase).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

Please note: New cases and deaths will be reported per 100 000 population instead of per 1 million population, starting from this report.

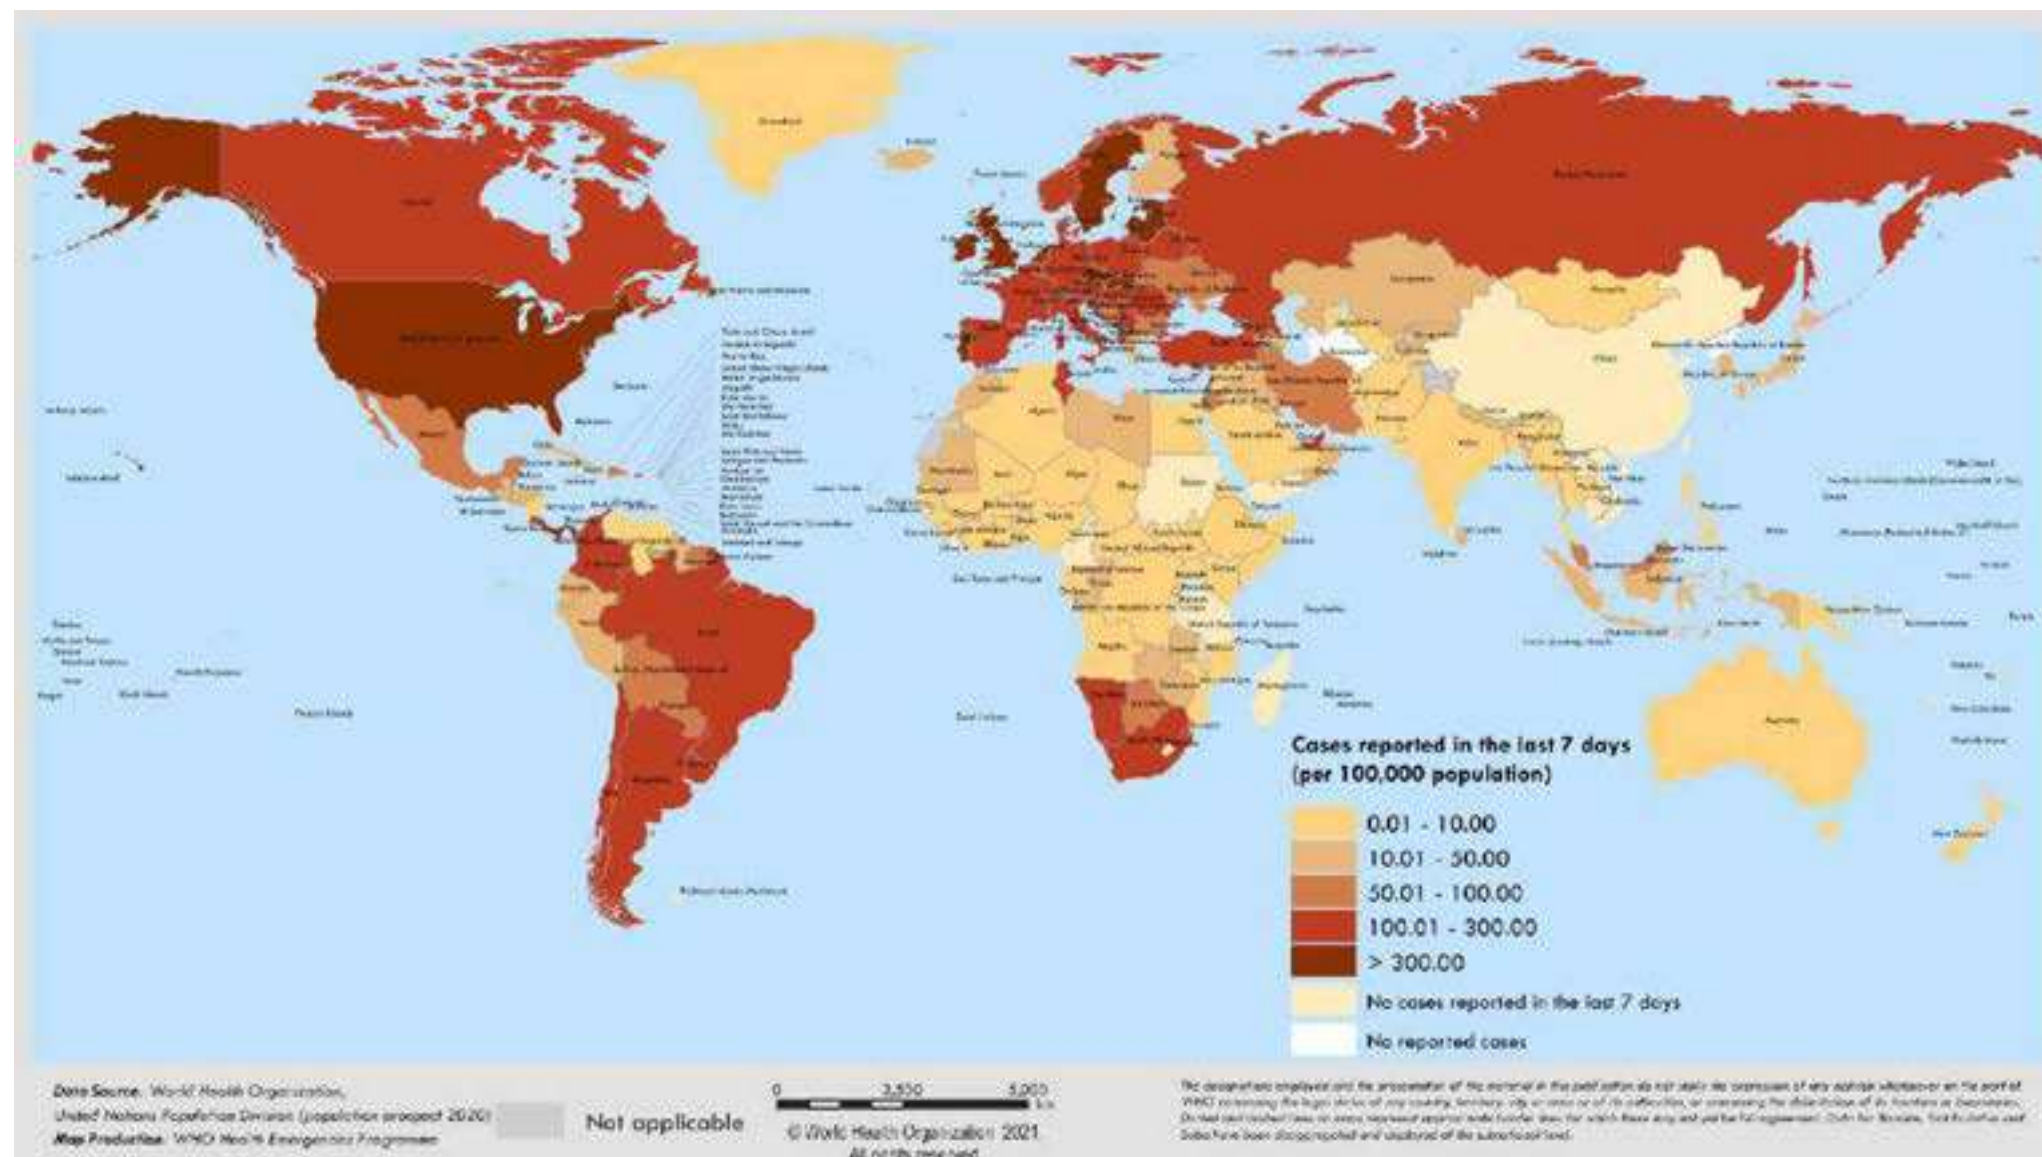

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 10 January 2021**

SARS-CoV-2 Variants of concern

Since the start of the COVID-19 pandemic, WHO has received several reports of public health events associated with variants of SARS-CoV-2. When considered to potentially have different epidemiological, immunological or pathogenic properties, variants are reported to WHO and raised for further investigation by national authorities. Further background on variants of concern (VOC) is available in [Disease Outbreak News](#) and the [Weekly Epidemiological Update](#) published 5 January. In collaboration with local authorities, institutions and researchers, WHO routinely assesses if variants of SARS-CoV-2 result in changes in transmissibility, clinical presentation and severity, or if they may impact on countermeasures, including diagnostics, therapeutics and vaccines. While investigations are ongoing, in the following update, we highlight the geographical extent of two variants – VOC 202012/01 (initially identified in the United Kingdom) and 501Y.V2 (initially identified in South Africa) – reported by countries, territories and areas as of 12 January 2021, as well as highlight recent reports of other new variants of potential concern.

Since first detected on 14 December 2020, VOC 202012/01 has been detected in 50 countries, territories and areas across five of the six WHO regions to date (Figure 3). In England, the variant has been detected in all regions and almost all local authorities. Here, investigations are using a proxy S gene target failure (SGTF) to indicate carriage of the VOC, as only a small proportion of these variants is detected using whole genome sequencing, which lags approximately two weeks behind the initial test date. Results show that the age and sex distribution of VOC 202012/01, as determined by SGTF, is similar that of other variants in circulation over the same period. Analyses using contact tracing data showed higher transmissibility (secondary attack rates) where the index case has the variant strain, from around 11% to 15% of named contacts.

Since first reported on 18 December 2020, variant 501Y.V2 has been detected in 20 countries, territories and areas across four of the six WHO regions (Figure 4). From preliminary and ongoing investigations in South Africa, it is possible that the 501Y.V2 variant is more transmissible than variants circulating in South Africa previously. Moreover, while this new variant does not appear to cause more severe illness, the observed rapid increases in case numbers has placed health systems under pressure.

On 9 January, Japan notified WHO of a new SARS-CoV-2 variant within lineage B.1.1.28 (initially reported as B.1.1.248) detected in four travelers arriving from Brazil. This variant has 12 mutations to the spike protein, including three mutations of concern in common with VOC 202012/01 and 501Y.V2, i.e.: K417N/T, E484K and N501Y, which may impact transmissibility and host immune response. Researchers in Brazil have additionally reported the emergence of a similar variant also with a E484K mutation, which has likely evolved independently of the variant detected among Japanese travelers. The extent and public health significance of these new variants require further investigation.

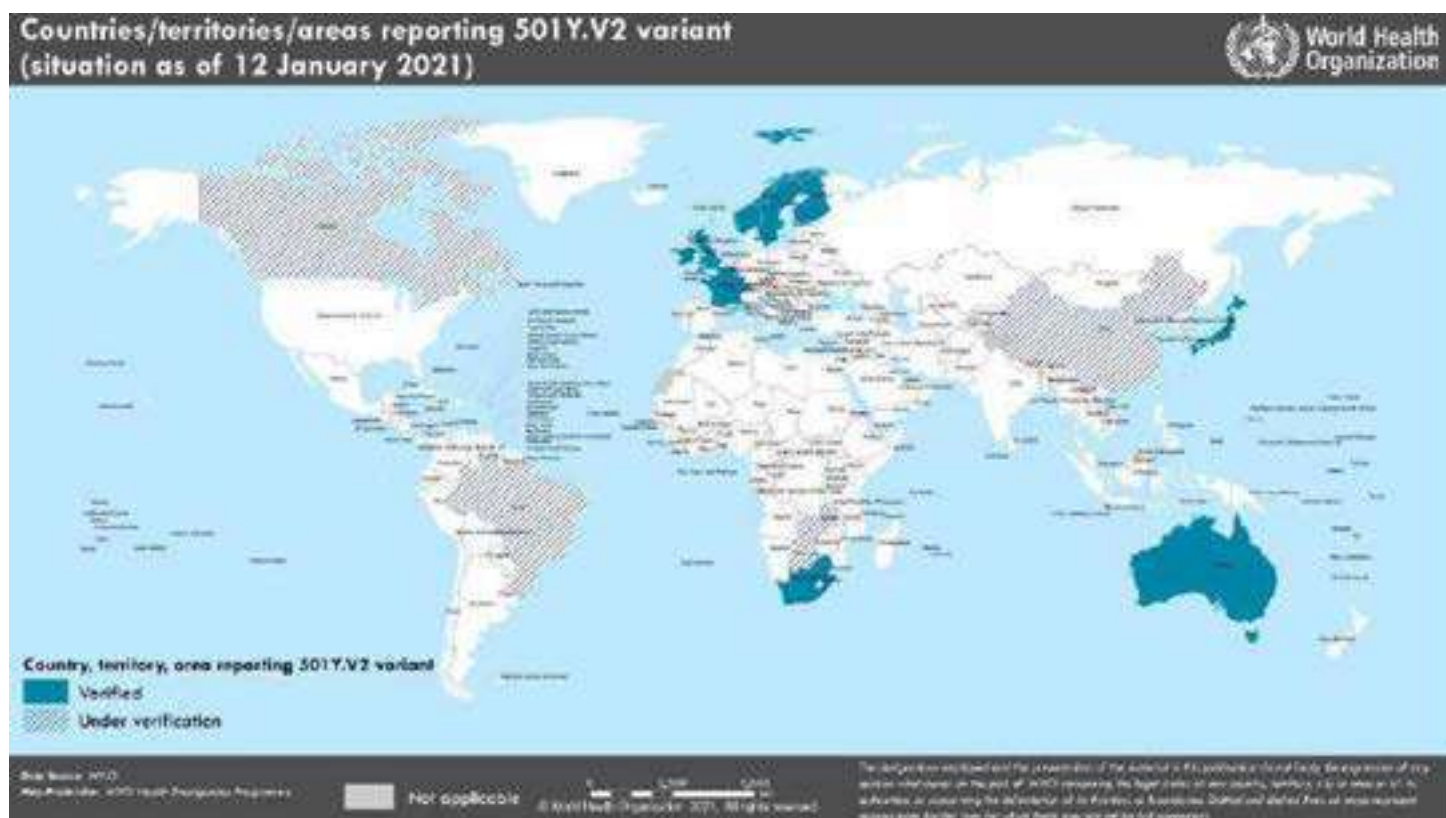

It is well known that viruses constantly change through mutation, and so the emergence of new variants is an expected occurrence. Many mutations have no impact on the virus itself while some could be detrimental to the virus and few may result in an advantage to the virus. These variants of concern identified in different countries highlight the importance of increasing diagnostic capacity and systematic sequencing of SARS-CoV-2 where capacity allows, as well as the timely sharing of sequence data internationally.

Systematic sequencing should be considered for a subset of incoming travellers, as well as community-based samples to ascertain the existence and extent of local transmission. The geographical extent of both VOC 202012/01 and 501Y.V2 reported above is likely underestimated given a bias toward countries/territories/areas detecting the variants with sequencing capacity, and where surveillance systems have been adapted to detect these new variants. Irrespective of sequencing capacity in countries, surveillance through established systems and regular epidemiology analyses should continue to inform adjustments to public health and social measures. Research is ongoing to determine the impact of new variants on transmission, disease severity as well as any potential impacts on vaccines, therapeutics and diagnostics. These efforts will require coordination of research between WHO, partners and groups of international scientists (WHO Virus Evolution Working Group).

Figure 3. Countries, territories and areas reporting SARS-CoV-2 202012/01 variant as of 12 January 2021

Figure 4. Countries, territories and areas reporting SARS-CoV-2 501Y.V2 variant as of 12 January 2021

Situation by WHO Region

African Region

In the past week, the African Region reported the highest percentage increases in both cases and deaths compared to the previous week. Over 174 000 new cases and over 4300 deaths were reported, increases of 34% and 31% respectively. Cases in the Region have been increasing since mid-September 2020 but steeper increases have been observed since late November. The highest numbers of new cases were reported in South Africa (125 287 new cases; 211.2 new cases per 100 000 population; a 27% increase), Nigeria (8315 new cases; 4.0 new cases per 100 000; a 49% increase) and Zimbabwe (6008 new cases; 40.4 new cases per 100 000; a 293% increase).

The countries reporting the highest number of new deaths in the past week were South Africa (3649 new deaths; 6.2 new deaths per 100 000; a 37% increase), Zimbabwe (106 new deaths; 0.7 new deaths per 100 000; a 194% increase) and Zambia (72 new deaths; 0.4 new deaths per 100 000; a 620% increase).

Region of the Americas

Over 2.5 million new cases and over 38 000 new deaths were reported in the Region of the Americas this week, a 30% and 18% increase respectively, compared to the previous week. The countries reporting the highest number of new cases in the past week were the United States of America (1 786 773 new cases; 539.8 new cases per 100 000 population; a 35% increase), Brazil (313 130 new cases; 147.3 new cases per 100 000; a 24% increase) and Colombia (100 688 new cases; 197.9 new cases per 100 000; a 26% increase).

The highest number of new deaths this week were reported in the United States of America (20 633 new deaths; 6.2 new deaths per 100 000; a 20% increase), Brazil (6049 new deaths; 2.8 new deaths per 100 000; a 23% increase) and Mexico (5562 new deaths; 4.3 new deaths per 100 000; a 19% increase).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 171 000 new cases, an increase of 11% after a sustained decrease in cases from 23 November through the week of 28 December 2020. The new deaths continue to decrease for the seventh consecutive week with over 2700 new deaths (9% decrease) reported this week. The three countries reporting the highest number of new cases were Iran (42 964 new cases, 51.2 new cases per 100 000 population, a 1% increase), Lebanon (29 145 new cases, 427.0 new cases per 100 000, 72% increase) and United Arab Emirates (16 061 new cases, 162.4 new cases per 100 000, 49 % increase). These three countries accounted for almost half (52%) of the new weekly cases in the Region.

The highest number of new deaths were reported in Iran (662 new deaths, 0.8 new death per 100 000 population, 23% decrease) followed by Pakistan (340 new deaths, 0.2 new death per 100 000, 23% decrease) and Egypt (401 new deaths, 0.4 new death per 100 000, a 3 % increase). These countries accounted for almost 60% of deaths reported in the Region.

European Region

The European Region continues to report a substantial number of cases with over 1.8 million new cases and 36 000 new deaths, increases of 10% and 7% compared to the previous week, respectively. The three countries reporting the highest number of new cases remain the same as last week with United Kingdom (417 620 new cases; 615.2 new cases per 100 000, 21% increase), Russian Federation (165 167 new cases, 113.2 new cases per 100 000, 11% decrease) and Germany (142 861 new cases, 170.5 new cases per 100 000, 14% increase). These three countries accounted for almost 40% of all cases reported in the region with the United Kingdom accounting for 23% of all new cases.

The highest numbers of deaths were reported from the United Kingdom (6298 new deaths; 9.3 new deaths per 100 000, 51% increase), Germany (6071 new deaths; 7.2 new deaths per 100 000, 35% increase), and Italy (3409 new deaths; 5.6 new deaths per 100 000, a 1 % increase).

South-East Asia Region

The South-East Asia Region reported similar numbers of new cases and deaths, with an overall declining trend observed since early September 2020. Just over 200 000 new cases and 3200 new deaths were reported in the past week, a 1% and 12% decrease respectively, compared to the previous week. The three countries reporting the highest number of new cases and new deaths were India (126 319 new cases; 9.2 new cases per 100 000, a 7% decrease; 1564 new deaths; 0.1 new death per 100 000, a 14% decrease), Indonesia (59 913 new cases; 21.9 new cases per 100 000; a 16% increase; 1392 new deaths; 0.5 new death per 100 000, a 11% decrease) and Bangladesh (6198 new cases; 3.8 new cases per 100 000; a 13% decrease; 157 new deaths; 0.1 new death per 100 000; an 8% decrease). India has consistently reported the highest number of new cases and deaths cumulatively in the region since the end of the first week of April 2020.

Western Pacific Region

In the past week, the Western Pacific Region reported an increase in the number of new cases by 36% (over 71 000) and new deaths by 14% (over 800) compared to the previous week. An upward trend in new weekly cases has been reported since late October 2020. The three countries reporting the highest numbers of new cases this week were Japan (39 821 new cases; 31.5 new cases per 100 000, a 68% increase), Malaysia (16 186 new cases; 50.0 new cases per 100 000, a 20% increase) and the Philippines (8881 new cases; 8.1 new cases per 100 000, a 12% increase).

The three countries reporting the highest numbers of new deaths this week were Japan (448 new deaths; 0.4 new deaths per 100 000, a 34% increase), the Republic of Korea (163 new deaths; 0.3 new deaths per 100 000, a 6% increase) and the Philippines (145 new deaths; 0.1 new deaths per 100 000, a 22% decrease).

Table 2. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region, as of 10 January 2021**

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps

represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 3 January 2021, 10 am CET

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

For the third week in a row over 4 million new cases were reported globally, although this week saw a slight decrease compared to the previous week. However, this and other short-term trends in data should be interpreted with caution owing to the end-of-year holiday season, as numbers may be influenced by presentation, testing and reporting delays. The decrease seen last week in new deaths has been reversed with deaths rising by 3% to 76 000 (Figure 1, Table 1). The Region of the Americas accounted for 47% of all new cases and 42% of all new deaths globally in the past week. New cases and deaths remained high in the European Region, which accounted for 38% and 43% respectively, showing a slight decrease in new cases and a slight increase in new deaths. New cases and deaths continue to decline in the South-East Asia and Eastern Mediterranean regions. In the African Region, while both new cases and deaths remain low in absolute numbers, for the fourth week in a row, the Region is reporting the largest percentage increase globally in weekly reported case numbers and this week there was a further 13% increase in new cases and 28% increase in new deaths. In the Western Pacific Region, new cases remained comparable to the previous week, but new deaths rose by 10%. As we welcome the New Year, and look eagerly towards COVID-19 vaccination campaigns worldwide, the current epidemiological situation with near record numbers of new cases and deaths, makes it imperative to continue to adhere to safety measures to prevent further transmission and loss of life.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 3 January 2021**

Recent reports of different variants of SARS-CoV-2, the virus that causes COVID-19, have again raised interest in and concern about the impact of viral changes. In the last months, [two different variants of SARS-CoV-2 have been reported to WHO as unusual public health events from the United Kingdom of Great Britain and Northern Ireland, referred to as VOC 202012/01, and the Republic of South Africa, named 501Y.V2](#). Preliminary epidemiologic, modelling, phylogenetic and clinical findings suggest that SARS-CoV-2 VOC 202012/01 has increased transmissibility, and preliminary data also indicates that there is no change in disease severity (as measured by length of hospitalization and 28-day case fatality), or occurrence of reinfection between variant cases compared to other SARS-CoV-2 viruses circulating in the United Kingdom. To date, outside of the United Kingdom, 40 countries across five of the six WHO regions have reported cases of VOC 202012/01, while outside of South Africa six countries, in two of the six WHO regions have reported cases of 501Y.V2. The authorities in both countries are conducting further epidemiological and virological investigations to further assess the transmissibility, severity, risk of reinfection and antibody response to these new variants, as well as potential impact on countermeasures, including diagnostics, therapeutics and vaccines.

In the past week, the five countries reporting the highest number of cases were the United States of America (with 1 325 424 cases, just under a third of global cases and unchanged from last week), the United Kingdom of Great Britain and Northern Ireland (343 784 cases, continuing last week's rapid increase with a 36% increase), Brazil (252 018 cases, an 11% decrease), the Russian Federation (186 539 cases, a 7% decrease) and India (136 115 cases, a 13% decrease).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

Situation by WHO Region

African Region

In the past week, over 130 000 new cases were reported in the African Region, a 13% increase compared to the previous week, and over 3000 deaths, a 4% increase over the previous week. In the past week, South Africa reported the highest number of new cases (93 978 new cases; 1585 new cases per 1 million population), Nigeria (5587 new cases; 27 new cases per 1 million), Mauritania (3393 new cases, 730 new cases per 1 million) and Namibia (3256 new cases, 1281 new cases per 1 million). The highest numbers of new deaths were reported from South Africa (2654 new deaths; 45 new deaths per 1 million), Mauritania (122 new deaths; 26 new deaths per 1 million) and the Kingdom of Eswatini (64 new deaths; 55 new deaths per 1 million).

Region of the Americas

In the Region of the Americas, the number of new weekly cases remained at similar levels to last week with over 1.9 million new cases and 32 000 new deaths reported (a slight fall of 1% and rise of 3% respectively from last week). The highest new case counts were reported in the United States of America (1 325 424 new cases, 4004 new cases per 1 million), Brazil (252 018 new cases; 1186 new cases per 1 million) and Colombia (80 173 new cases, 1576 new cases per 1 million). The highest numbers of new deaths were reported from the United States of America (17 239 new deaths; 52 new deaths per 1 million), Brazil (4923 new deaths; 23 new deaths per 1 million) and Mexico (4670 new deaths; 36 new deaths per 1 million).

Eastern Mediterranean Region

In the past week, the Eastern Mediterranean Region reported over 154 000 new cases and over 3000 new deaths, a decrease of 1% and 12%, respectively compared to the previous week. Cases and deaths in the Region decreased for the sixth consecutive week. The highest number of new cases were reported from the Islamic Republic of Iran (42 511 new cases, 506 new cases per 1 million), Lebanon (16 936 new cases, 2841 new cases per 1 million) and Pakistan (14 880 new cases, 67 new cases per 1 million). These three countries accounted for almost half (48%) of new weekly cases in the Region. The highest number of new deaths were reported from the Islamic Republic of Iran (864 new deaths; 10 new deaths per 1 million), Pakistan (442 new deaths; 2 new deaths per 1 million) and Egypt (389 new deaths; 4 new deaths per 1 million).

European Region

The European Region continues to report a large number of cases with over 1.5 million new cases and 3200 new deaths, a 3% decrease and 2% increase compared to the previous week, respectively. New weekly cases have decreased for the past two weeks. The Region reported the highest proportion (43%) of global new deaths among all regions. Last week, the countries reporting the highest number of new cases were the United Kingdom of Great Britain and Northern Ireland (343 784 new cases, 5064 new cases per 1 million), the Russian Federation (186 539 new cases; 1278 new cases per 1 million) and Germany (124 808 new cases; 1490 new cases per 1 million). The highest number of deaths were reported from Germany (4494 new deaths; 54 new deaths per 1 million), the United Kingdom (4165 new deaths; 61 new deaths per 1 million) and the Russian Federation (3728 new deaths; 26 new deaths per 1 million).

South-East Asia Region

New cases and deaths in the South-East Region have continued to decrease, a trend observed since early September. Just over 200 000 new cases and 3700 new deaths were reported this week, a 10% and 3% decrease respectively, compared to the previous week. The three countries reporting the highest number of new cases and new deaths were India (136 115 new cases; 99 new cases per 1 million; 1813 new deaths; 1 new death per 1 million), Indonesia (51 636 new cases; 189 new cases per 1 million; 1561 new deaths; 6 new deaths per 1 million) and Bangladesh (7085 new cases; 43 new cases per 1 million; 171 new deaths; 1 new death per 1 million). India has consistently reported the highest number of new cases and deaths since the end of the first week of April 2020.

Western Pacific Region

In the past week, there has been little change in the number of new cases (just under 53 000) reported in the Western Pacific Region, while new deaths increased by 10% (over 700) compared to the previous week. The plateau in new cases over the past week comes after four weeks of increasing trends. The three countries reporting the highest number of new cases this week were Japan (23 642 new cases; 187 new cases per 1 million), Malaysia (13 473 new cases; 416 new cases per 1 million) and Philippines (7911 new cases; 72 new cases per 1 million). The three countries reporting the greatest number of new deaths this week included Japan (335 new deaths; 3 new deaths per 1 million), Philippines (186 new deaths; 2 new deaths per 1 million) and the Republic of Korea (154 new deaths; 3 new deaths per 1 million).

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.

- Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 27 December 2020, 10 am CET

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Globally in the past week, over 4 million new cases were reported. Although this is a 12% decrease compared to the previous week, this and other short-term trends in data should be interpreted with caution over the end-of-year holiday season, as numbers may be influenced by presentation, testing and reporting delays. New deaths decreased by 8% to 72 730 (Figure 1, Table 1). The Region of the Americas accounts for 48% of all new cases and 42% of all new deaths globally. While new cases and deaths remained high in the European Region, which accounted for 37% and 42% respectively, both decreased compared to the previous week. New cases and deaths declined in South-East Asia and Eastern Mediterranean regions. In the African Region, while both new cases and deaths remained low compared to other regions, there was a 20% increase in new cases and 37% in new deaths. In the Western Pacific Region, new cases increased by 13% and new deaths increased by 4%.

As of 27 December there have been over 79.2 million cases and over 1.7 million deaths reported since the start of the pandemic.

A variant of SARS-CoV-2 has been detected in South Africa through retrospective genomic analyses of the virus. Initial analysis indicates that the variant, known as 501Y.V2, may spread more readily between people. Investigations are ongoing to determine if it is associated with any change in the severity of infection, antibody response or vaccine efficacy.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 27 December 2020**

In the past week, the five countries reporting the highest number of cases were the United States of America (with over 1.3 million cases, a 19% decrease from the previous week), Brazil (over 285 000 cases, a 12% decrease), the United Kingdom of Great Britain and Northern Ireland (over 251 000 cases, a 45% increase), Russian Federation (over 201 000 cases, a 3% increase) and India (over 156 000 cases, a 10% decrease).

Situation by WHO Region

African Region

In the past week, over 114 000 new cases were reported in the African Region, a 20% increase compared to the previous week, and over 2500 deaths, a 37% increase over the previous week. South Africa continues to account for the greatest proportion (72%) of new weekly cases in the Region. In the past week, the highest number of new cases were reported from South Africa (82 434 new cases; 1390 new cases per 1 million population), Nigeria (5643 new cases; 27 new cases per 1 million), Algeria (3076 new cases, 70 new cases per 1 million) and Namibia (2961 new cases, 1165 new cases per 1 million). The highest numbers of new deaths were reported from South Africa (1982 new deaths; 33 new deaths per 1 million), the Democratic Republic of the Congo (197 new deaths; 2 new deaths per 1 million) and Algeria (63 new deaths; 1 new death per 1 million).

Region of the Americas

In the Region of the Americas, the number of new weekly cases was over 1 965 000 and 31 142 new deaths, which represent 15% and 3% decreases over the previous week, respectively. The United States of America accounted for 68% of all new cases in the Region. The highest new case and deaths counts were reported in the United States of America (1 334 155 new cases, 4031 new cases per 1 million), Brazil (285 582 new cases; 1344 new cases per 1 million) and Colombia (92 635 new cases, 1821 new cases per 1 million). The highest numbers of new deaths were reported from the United States of America (16 864 new deaths; 51 new deaths per 1 million), Brazil (2838 new deaths; 23 new deaths per 1 million) and Mexico (4588 new deaths; 36 new deaths per 1 million).

Eastern Mediterranean Region

The Eastern Mediterranean Region reported over 157 000 new cases and over 3400 new deaths, reflecting a reduction of 9% and 10%, respectively compared to the previous week. Cases and deaths in the Region decreased for the fifth consecutive week. The highest number of new cases were reported from the Islamic Republic of Iran (42 891 new cases, 511 new cases per 1 million), Morocco (15 336 new cases, 415 new cases per 1 million) and Pakistan (14 809 new cases, 67 new cases per 1 million). These three countries accounted for the most new cases in the previous two weeks. The highest number of new deaths were reported from the Islamic Republic of Iran (1126 new deaths; 13 new deaths per 1 million), Pakistan (566 new deaths; 3 new deaths per 1 million) and Tunisia (300 new deaths; 25 new deaths per 1 million).

European Region

The number of new cases in the European Region remains high with over 1.5 million reported in the past week. However, the number of new cases has declined over the past week, decreasing by 12%, while deaths decreased by 15% to 31 000 new deaths. Despite the observed reductions, the European Region continues to account for the second highest number of new cases and deaths globally (37% and 42% respectively). Last week, the countries reporting the highest number of new cases were the United Kingdom of Great Britain and Northern Ireland (251 786 new cases, 3709 new cases per 1 million), the Russian Federation (201 871 new cases; 1383 new cases per 1 million population) and Germany (146 849 new cases; 1753 new cases per 1 million). The highest number of deaths were reported from the same countries, namely Russian Federation (3920 new deaths; 27 new deaths per 1 million), Germany (3729 new deaths; 45 new deaths per 1 million) and the United Kingdom (3330 new deaths; 49 new deaths per 1 million).

South-East Asia Region

In the South-East Asia Region, nearly 232 000 new cases were reported last week, a decrease of 6% compared to the previous week, while new deaths were nearly 4000, a slight decrease of 1%. There has been an overall decline in both cases and deaths since the peak in the week beginning 7 September. The countries reporting the highest number of both new cases and new deaths in the past week were India (156 627 new cases; 113 new cases per 1 million; 2145 new deaths; 2 new deaths per 1 million), Indonesia (48 889 new cases; 179 new cases per 1 million; 1335 new deaths; 5 new deaths per 1 million) and Bangladesh (8539 new cases; 52 new cases per 1 million; 186 new deaths; 1 new death per 1 million).

Western Pacific Region

In the Western Pacific Region, new cases (13%) and deaths (4%) continued to increase, a trend which has been seen over the past eight weeks. The Region reported over 53 000 new cases and nearly 700 new deaths. The highest new cases were reported in Japan (21 432 new cases; 169 new cases per 1 million), Malaysia (11 931 new cases; 369 new cases per 1 million) and the Philippines (10 961 new cases; 100 new cases per 1 million). The countries reporting the highest number of new deaths this week were Japan (340 new deaths; 3 new deaths per 1 million), the Philippines (156 new deaths; 1 new death per 1 million) and the Republic of Korea (134 new deaths; 3 new deaths per 1 million).

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 745 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.

• Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 20 December 2020, 10 am CET. Other information collected by epidemic intelligence activities and verified by WHO.

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

New COVID-19 cases and deaths continued to increase during the past week, by 6% and 4% respectively (Figure 1, Table 1). The Region of the Americas again accounted for the greatest proportion, reporting over 2.3 million new cases (half of the global cumulative), while the European Region reported the highest number of new deaths (36 286; 46%) in the past week. The African Region accounted for the greatest relative increase in new cases (27%) and deaths (34%) compared to the previous week. Increasing trends were also observed in the Western Pacific Region, while the South-East Asia and Eastern Mediterranean Regions were the only two that reported a decrease in both cases and deaths.

On 14 December 2020, authorities from the United Kingdom of Great Britain and Northern Ireland (United Kingdom) reported a new variant of SARS-CoV-2 to WHO. It was identified by viral genomic sequencing, and is referred to as SARS-CoV-2 Variant Under Investigation, year 2020, month 12, variant 01 (SARS-CoV-2 VUI 202012/01). Initial analysis indicates that the variant may spread more readily between people. Investigations are ongoing to determine if it is associated with any change in the severity of infection, antibody response or vaccine efficacy.

As of 20 December there have been over 75 million cases and over 1.6 million deaths since the start of the pandemic.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 20 December 2020**

**See [data table and figure notes](#).

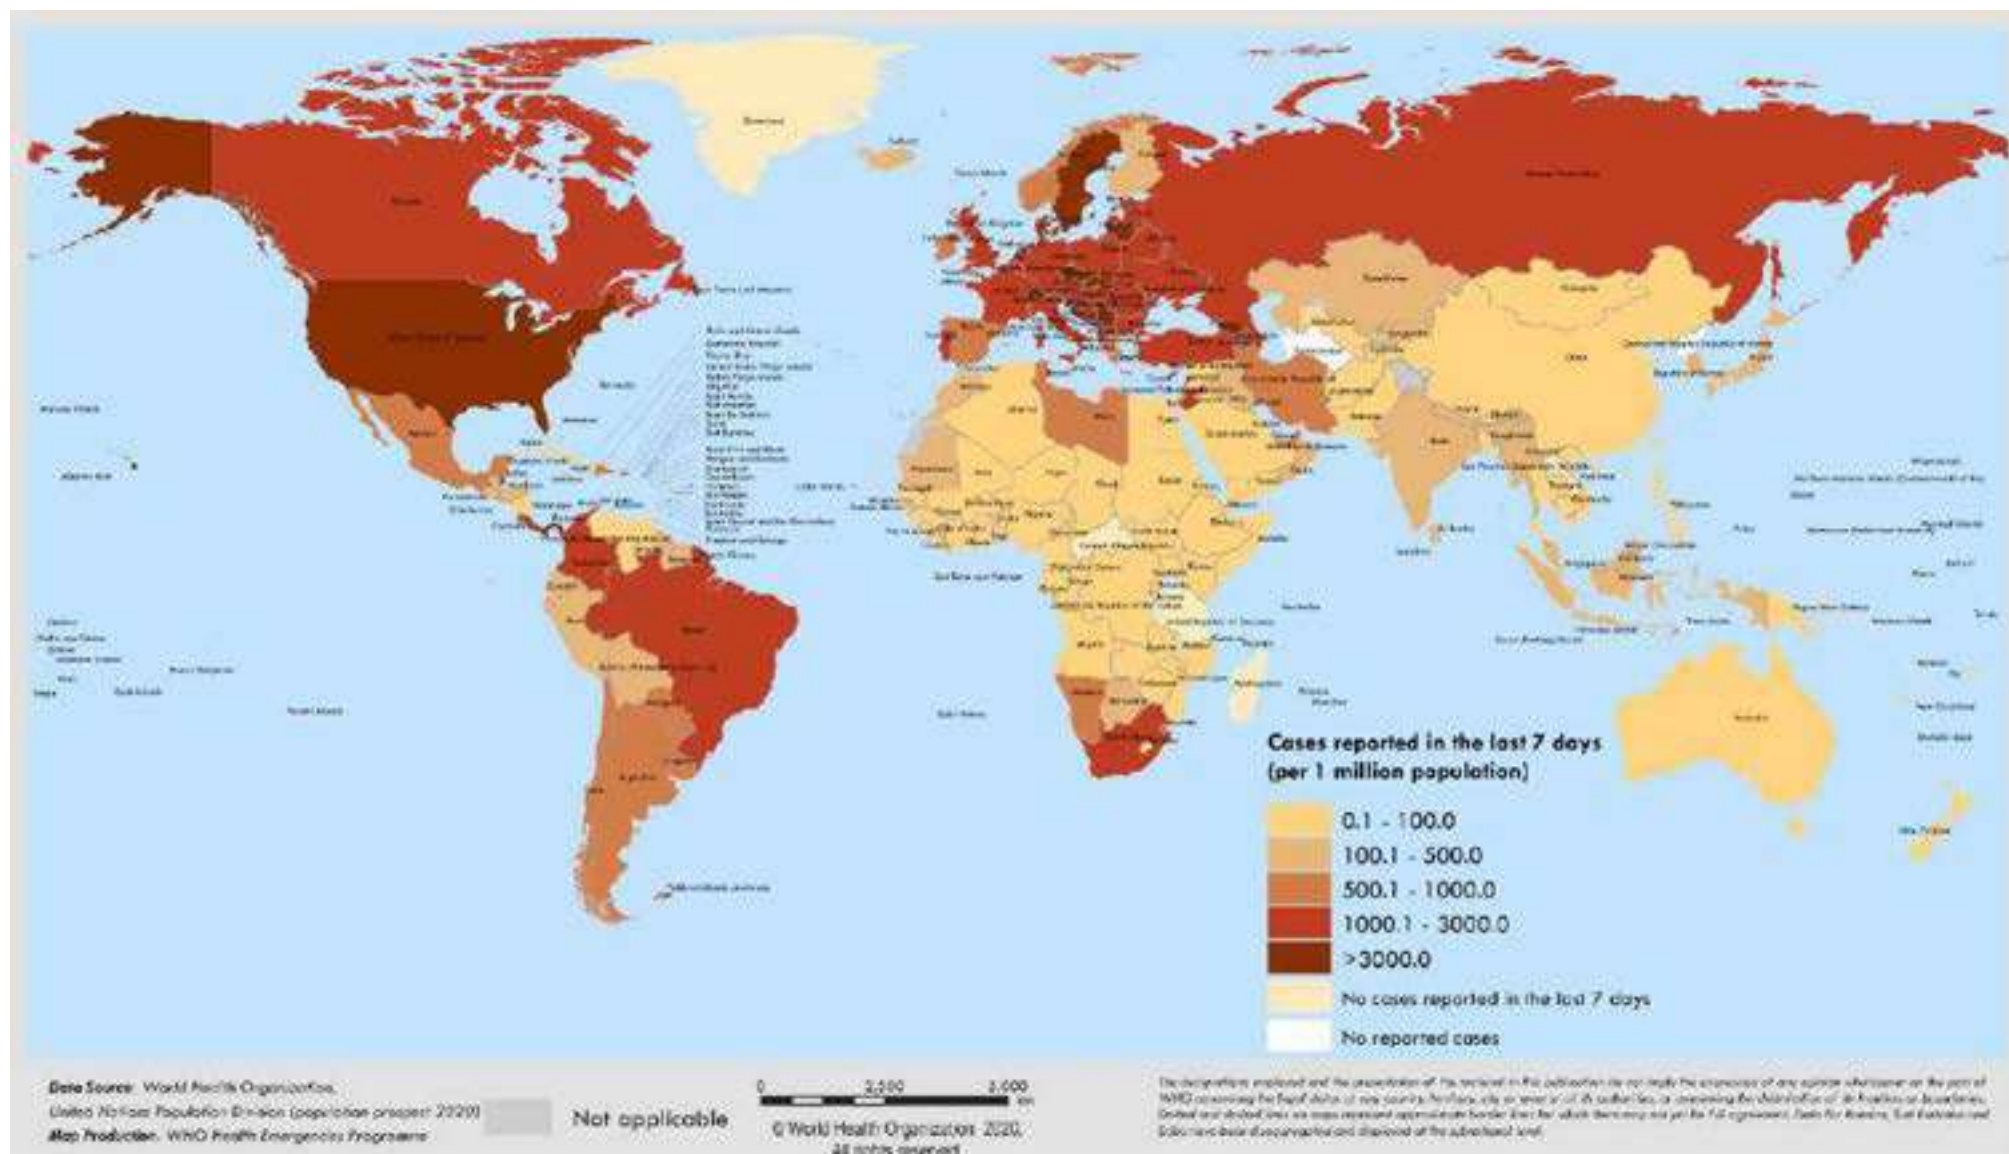

In the past week, the five countries reporting the highest number of cases globally were the United States of America with over 1.6 million cases, a 14% increase from the previous week, Brazil (326 751 new cases, an 8% increase from the previous week), Turkey (194 476 new cases, an 11% decrease from the previous week), the Russian Federation (194 449 new cases; less than a 1% increase from the previous week) and India (174 194 new cases; an 18% decrease from the previous week).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

Figure 2. COVID-19 cases per 1 million population reported in the last seven days by countries, territories and areas, 14 December through 20 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Situation by WHO Region

African Region

The African Region has continued to report a steady increase in new reported cases and deaths, with 27% and 34% increases respectively week on week. (Figure 3). The Region reported 94 653 new cases, constituting the highest overall change in case counts (Table 1). The number of new cases per 1 million population was 84 during the last week and a case fatality rate of 2.2%, since the start of the pandemic. The highest number of cases were reported from South Africa (59 512, 1 003 new cases per 1 million population), Nigeria (5 176, 25 new cases per 1 million population), Ethiopia (4 134, 36 cases per 1 million population), Kenya (3 846, 72 cases per 1 million population), Uganda (3 631, 79 cases per 1 million population) and Algeria (3 143, 72 cases per 1 million population).

South Africa continues to report high numbers of new cases and deaths, and has the highest case incidence (1003 new cases per 1 million population) within the region. As of 20 December 2020, the cases were mainly distributed in Gauteng (28%), Western Cape (19%), Eastern Cape (17%) and KwaZulu Natal (17%) provinces. New stay-at-home orders were implemented, as well as closures of some public beaches and parks, limiting alcohol selling hours and a curfew from 11pm to 4am. A new variant of SARS-CoV-2 was detected in South Africa and the changes observed may translate to higher transmissibility.

New cases reported in Eswatini have increased by 170%, bringing the cumulative to 7305 cases. The country reported an increased incidence of 509 new cases per million population compared to 189 cases per million population reported in the previous week. As of 14 December 2020, cases were mainly distributed in regions of Manzini (46%) and Hhohho (38%), according to the Ministry of Health. Reported deaths increased, though cumulative deaths remain low (137 deaths) compared to neighbouring countries, South Africa and Mozambique.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 20 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Region of the Americas reported over 2.3 million new cases this week, a 13% increase from the previous week (Figure 4). The Region also reported over 32 000 deaths, a 9% increase from the previous week and a continuation in the a rapid rise in deaths since November. The United States of America continues to report an increasing number of new cases (over 1.65 million new cases; over 5000 new cases per 1 million population) – the highest incidence in the Region. The United States of America is followed by Brazil, Colombia, Mexico and Canada in cases reported last week. The five countries with the highest number of deaths per 1 million population were Belize (75 deaths per 1 million), the United States of America (54 deaths per 1 million), Panama (45 deaths per million), Mexico (33 deaths per 1 million), and Colombia (27 deaths per 1 million).

The number of new cases reported last week in Argentina (over 42 000, 930 per 1 million population) represents a 21% increase from last week and pushes the cumulative number of cases above 1.5 million. This is the first increase in the number of new cases since a continuous downward trend from the week of 19 October, when new weekly cases peaked at 103 000. Despite this increase in new cases, the number of new deaths continued to decline, to just over 1000 new deaths reported last week, a 3% decline compared to the previous week. Buenos Aires province has reported the highest number of cumulative cases and accounts for 43% of cases, followed by the province of Santa Fé, the city of Buenos Aires and Córdoba province. Since the beginning of the pandemic, 4.3 million cumulative people have been tested, with a current test positivity rate of 30%. The occupancy rate of intensive care beds stands at 54%.

The number of new cases reported by Panama has risen rapidly since the week of 9 November. Last week, a 31% rise was seen compared to the previous week, with 18 500 new cases reported (4300 new cases per 1 million population – the second highest in the Region after the United States of America). The number of new deaths has also risen by 26% in comparison to the previous week, with 195 new deaths reported (45 new deaths per 1 million population). Public health and social measures including curfews are being implemented over the end-of-year holiday period. The government has approved the use of the Pfizer vaccine against COVID-19 and expects to start receiving the first batch in the first quarter of 2021.

In the Dominican Republic, new cases reported stabilized during the last week, to just under 5500 new cases (500 new cases per 1 million), an 8% decline from last week. As of 13 December, 790 000 polymerase chain-reaction (PCR) tests had been conducted, with a current test positivity rate around 15%. Around 30% of COVID-19 intensive care unit beds are currently occupied. Of those who have died, one third were reported to have hypertension, while 21% were diabetic, according to authorities. As with Panama, curfews will be implemented over the end-of-year holiday period.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 20 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

The number of new cases and deaths in the Eastern Mediterranean Region has decreased, for the fourth consecutive week (Figure 5). A cumulative 174 325 new cases (a 14% decrease compared to the previous week) and 3852 new deaths (a 12% decrease compared to the previous week) was reported in the past week. The countries reporting the highest number of new cases in the past week were the Islamic Republic of Iran (51 254 new cases; 610 new cases per 1 million population), Pakistan (19 617 new cases; 89 new cases per 1 million population) and Morocco (17 629 new cases; 478 per 1 million population). These three countries also accounted for the most deaths reported in the past week (table 2).

There has been a 40% increase in new cases in the Syrian Arab Republic in the past week, with over 1000 cases reported, while the number of new deaths increased by nearly 50%. Increases in new cases have been reported for the past eight weeks, and the case fatality rate is high, at just under 6%.

In Lebanon the number of new cases has increased by 20%, after five weeks of reporting decreases. The number of new deaths decreased by 21%. Most cases were male (54%) compared to female (46%), and the highest incidence per 100 000 population was reported in those aged 50-59 years since the start of the pandemic. Nationally, the cumulative incidence has been reported to be highest in the district of Aleyh (5 121 per 100 000 population), while the incidence in the past 14 days has been highest in the district of Zahleh (655 per 100 000 population). A new COVID-19 department was opened in the Othman Hospital in Kuterma -- Al-Kharroub region of Lebanon -- along with an increase in the number of beds and intensive care units in two other hospitals: Al-Koura Hospital and Shaheen Hospital.

Both cases and deaths continued to increase in Egypt during the last week. The number of cases increased by 24%, representing the largest relative increase reported in the past two months. The number of new deaths increased by 16%. There was a cluster of cases reported among the youth national football team. The Minister of Health stated early in December that 56% of intensive care unit beds and 30% of ventilators are currently occupied, while the occupancy of beds for isolation is 24%. In an effort to address the rising number of cases and deaths, a grant will be used to scale up medical supplies.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 20 December 2020**

*See [data](#), [table](#) and [figure notes](#)

European Region

The increase in the number of new cases (2%) and deaths (3%) reported last week in the European Region remained very similar to the previous week (Figure 6). The highest number accounting for 33% of all cases reported in the Region, were in Turkey (194 476 new cases; 2306 new cases per 1 million population), the Russian Federation (194 449 new cases; 1332 new cases per 1 million population) and Germany (173 293 new cases; 2068 new cases per 1 million population). The highest number of new deaths were reported in Italy (4411 new deaths; 73 new deaths per 1 million population), Germany (4262 new deaths; 51 new deaths per 1 million population) and the Russian Federation (3917 new deaths; 27 new deaths per 1 million population).

For the ninth consecutive week, the number of cases and deaths increased in Estonia. Last week, while the number of new cases reported in Estonia increased by 27%, the number of new deaths increased by 18%. The country has reported peaks in new cases and deaths, with the most affected counties being Harju, Ida-Viru and Tartu. The average age of hospitalized cases was 67 years; 69 years for among females and 65 years among males. In response to these increases, public health and social measures were tightened on 14 December. Estonia has conducted over 565 000 PCR tests. The case fatality rate (0.8%) remains low, the test positivity rate is relatively high at 11%.

In Portugal, following three weeks of a decline in the incidence of cases and deaths, both remained relatively stable in the past week. The number of new cases in the country was highest in Mandim de Basto, Marvao and Chaves counties. As of 20 December, there were 3158 hospitalized cases, of which 502 (16%) are in intensive care unit. The number of new reported deaths in the country was the highest reported since the start of the pandemic.

The number of cases in Spain have decreased for the seventh consecutive week, dropping slightly (2%), with a much larger decrease in the number of new deaths (a 44% decrease). The regions with the highest incidence per 100 000 population were Palencia (172) and Girona (159), while Palencia also had the highest incidence per 100 000 in those aged over 65 years (247). Approximately 20% of intensive care unit beds in the country are occupied by COVID-19 patients.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 20 December 2020**

**See data, table and figure notes

South-East Asia Region

The Region reported just over 249 000 new cases and under 4000 new deaths, 14% and 10% decreases respectively (Figure 7). This continues the declines observed since the middle of September. Only two countries out of ten in the Region reported an increase in new cases (Thailand and Indonesia). India has now reported over 10 million cases, and despite the number of new cases falling by 18% this week, the country reported the fifth highest number of new cases globally (174 000 new cases, 126 new cases per 1 million population). In the Region, India was followed by Indonesia, Bangladesh, Myanmar and Nepal in the number of new cases and new deaths reported last week.

Myanmar reported 8300 new cases (150 new cases per 1 million population) last week, an 11% decline from the previous week. Although cases were first reported in Myanmar in March, fewer than 1000 cases were reported by mid-August. The number of weekly new cases started to rise at the end of August and has remained between 6000 and 11 000 since the end of September. The townships of Mingaladon, North Okkalapa, Hlaingtharya, and Insein, which are close to the capital, Yangon, have reported the highest numbers of cumulative cases. As of 20 December, 1.6 million PCR tests had been conducted, with a current test positivity rate of 4%.

Sri Lanka reported 3900 new cases (180 new cases per 1 million), a 20% decline from last week. Weekly new cases rose considerably in the beginning of October, and new weekly cases have remained between 2500 and 5000 since the end of October. The number of deaths due to COVID-19 has remained low, with a current case fatality rate of 0.5%. As of 13 December, 1 million PCR tests have been conducted, with a current positivity rate of 4%.

Thailand reported 139 new cases last week (2 new cases per 1 million population), a 16% increase from the previous reporting period. Thailand has been successful at keeping the number of new cases below 100 per week from the end of April to early November. However, since the week of 9 November, the number of new weekly cases has risen steadily. A new outbreak in Samut Sakhon province was reported on 21 December, and accounts for a considerable proportion of the number of new cases. There have been no new deaths reported since 2 November. As of 6 December, 1.3 million PCR tests have been conducted, with a test positivity rate of 0.3%.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 20 December 2020*

Western Pacific Region

The numbers of new cases and deaths reported in the Western Pacific Region have been increasing consistently but gradually over the past seven weeks. New weekly cases increased by 3% in the past week (Figure 8). The Region continues to report the lowest number of new cases compared to other regions, with 46 662 new cases and 636 deaths reported. Japan continued to report the highest number of new cases and deaths (18 593 and 311 respectively), followed by Malaysia (9723 new cases, 22 new deaths), Philippines (9713 new cases, 181 new deaths) and the Republic of Korea (6899 new cases, 94 new deaths).

The Republic of Korea reported 94 deaths, a 169% increase in new weekly deaths compared to the previous week with 35 deaths. Due to the increasing number of new cases since November 2020, the Seoul metropolitan area is facing challenges in the availability of critical care beds, with 580 patients waiting for beds in Seoul as of 18 December, of which nearly half have been waiting for at least two days. In response to the continued rise in number of new cases, the government toughened preventive measures in Seoul to Level 2.5, the second highest level under the five-tier system.

In the past week, Singapore reported the highest increase (55%) in new weekly cases in the region. While the country reported 90 new cases last week, all were imported and had been issued stay-at-home notices or were isolated on arrival, preventing further transmission in the community. The country will be moving from Phase 2 to Phase 3 of its reopening starting 28 December 2020, allowing gatherings of eight people ahead of the new year. Singapore approved the Pfizer-BioNTech vaccine and announced that they expect to have enough for the whole country by the third quarter of 2021.

Key weekly updates

To mark the end of the [Year of the Nurse and Midwife](#), WHO has unveiled the [2020 List of 100+ Outstanding Women Nurses and Midwives](#). This partnership between WHO, [UNFPA](#), [Nursing Now](#), the International Council of Nurses ([ICN](#)), the International Confederation of Midwives ([ICM](#)), and Women in Global Health ([WGH](#)) features the achievements and contributions of nurses and midwives from 43 countries and across six global regions, to recognize these women and the millions of nurses and midwives around the world.

COVAX now has agreements in place to access nearly [two billion doses of several promising vaccine candidates](#), and laid the groundwork for further doses to be secured through contributions from donors. These agreements mean that all COVAX's 190 participating and eligible economies will be able to access doses to protect vulnerable groups in the first half of 2021. At least 1.3 billion donor-funded doses will be made available to 92 countries eligible for the Gavi COVAX AMC, targeting up to 20% of each country's population by the end 2021.

WHO and YouTube have partnered on a [public service announcement](#) to help battle COVID-19 fatigue.

The COVID-19 pandemic has had a negative impact on the living and working conditions of refugees and migrants according to a [new WHO study](#), launched on 18 December, International Migrants Day. It shows that people living on the streets and in asylum centres are less likely than the general population to seek care if they have symptoms of COVID-19. More than half of those surveyed said that COVID-19 has caused them depression, worry, anxiety and loneliness.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their cumulative counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. Retro-adjustments can also affect the percentage change reported in Table 1, with the percentages reflecting retro-adjustments made over the past week. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 744 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its

authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

Data for Bonaire, Sint Eustatius and Saba have been disaggregated and displayed at the subnational level.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19:](#)

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 13 December 2020, 10 am CET. Other information collected by epidemic intelligence activities and verified by WHO.

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

In the past week the number of new COVID-19 cases and deaths continued to rise with 70 million cumulative cases and 1.6 million deaths globally since the start of the pandemic. The Regions of the Americas and Europe continue to shoulder the burden of the pandemic, accounting for 85% of new cases and 86% of new deaths globally. However as new cases and new deaths continue to rise in the Americas, in cases stabilised in Europe for the third week in a row, while deaths continued to decrease. The African and the Western-Pacific Regions have both shown renewed rises in November and December. This week the African Region reported a rise in new cases and new deaths of over 40% compared with the previous week. In the South-East Asia Region, the number of new cases and deaths continued to decline following a peak in September. The Eastern Mediterranean Region also reported a decline in new cases and deaths from a peak in mid-November.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 13 December 2020**

**See [data table and figure notes](#).

In the past week, the five countries reporting the highest number of cases globally were the United States of America (reporting over 1.4 million cases, a 16% increase from the previous week), Brazil (300 000 new

cases, a 2% increase), Turkey (220 000 cases, no change from last week), India (210 000 cases, a 15% decrease), and the Russian Federation (193 000 new cases, a 1% increase).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

Situation by WHO Region

African Region

Following a decline in July and August and a plateau in September and October, the number of new cases and deaths has consistently increased since the beginning of November (Figure 3). In the last week, the number of new cases and deaths reported increased by 40% (to 74 500 new cases) and 43% (to 1 400 new deaths), respectively compared with the previous week. Several countries in the Region are reporting a resurgence in both cases and deaths including Mali, Namibia, Nigeria, Senegal and South Africa.

South Africa has reported the highest number of cumulative cases and deaths in the Region, with more than 850 000 confirmed cases and over 23 000 deaths. In the last week, 42 500 new cases (700 new cases per 1 million population) and 1 000 new deaths (18 new deaths per 1 million population) were reported. Four provinces including Eastern Cape, Gauteng, KwaZulu-Natal and Western Cape were most heavily affected, collectively accounting for 84% of all newly reported cases. The increase in affected provinces is expected to continue as the number of cases among those aged 15 to 19 years continues to increase. This increase could be partly attributed to end-of-school-year celebrations during which many adolescents gathered in large numbers.

In Uganda, the number of reported cases has continued to increase and in the last seven days, just under 5 000 cases were reported (100 new cases per 1 million population), a 118% increase from the previous week. The districts of Kampala, Kasese, Luwero, Mbarara and Wakiso have consistently reported the highest number of cases for the past three weeks, with Kampala the most affected. So far in the pandemic, a total of 1 516 cases, including 13 deaths, have been reported among health care workers, with the highest number reported in the week commencing 23 November, during which over 150 cases in health care workers were reported.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 13 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Region of the Americas has consistently reported the largest proportion of cases and deaths globally, and in the past week accounted for 47% and 40% of global cases and deaths respectively. In the past week, over 2 million cases and nearly 30 000 deaths were reported, which is the highest reported in the Region since the start of the pandemic. This represents an 11% increase in cases and a 12% increase in deaths compared to the previous week.

Last week, the United States of America reported an increase of 16% in cases (1.45 million new cases, 4 400 new cases per 1 million population) and a 21% increase in deaths (16 600 new deaths, 50 new deaths per 1 million population), compared to the previous week, as cases continue to rise after the Thanksgiving holiday in November. The daily number of deaths reported exceeded 3 000 during the last week, higher than the peak observed in the spring. Further increases in cases and deaths are expected due to the upcoming holiday season with more people travelling into and around the country. Hospitalization rates for COVID-19 cases have grown considerably since the beginning of October. Kentucky, Georgia, Minnesota, Oklahoma and Texas are the most affected, with counties reporting high hospital occupancy rates.

Bermuda has reported a cumulative total of nearly 400 cases and nine deaths since the start of the pandemic. However, since the beginning of December, the number of cases has increased substantially. In the last week, 103 new cases were reported (1 650 new cases per 1 million population) a 150% increase from the previous week. Approximately 30% of the total number of cases have been imported. Visitors are not required to quarantine on arrival if they provide a valid negative COVID-19 test taken at least five days before arrival. Due to the rapid rise in cases, public health and social measures were implemented on 12 December including a curfew, early closure of businesses, and restrictions on gatherings.

Uruguay has reported a 48% increase in the number of new cases to 2 100 new cases (610 new cases per 1 million population) and a 67% increase in the number of deaths to 10 new deaths (3 new deaths per 1 million) in comparison to previous week. The test positivity rate has also increased in the last couple of weeks and is currently 5.1%. The capital, and largest city in Uruguay, Montevideo is the most affected area accounting for over 60% of cases.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 13 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

Compared with the previous reporting week, this week the Region reported a 17% decline in new cases to just over 200 000 cases and a 14% decline in new deaths to 4 400 deaths. This extends the decline observed since mid-November when new cases peaked at around 250 000 and new deaths at just over 6 000. The Islamic Republic of Iran, Pakistan, Morocco, Jordan, and the occupied Palestinian territory reported the highest number of cases, although all these countries except Pakistan reported declines in the number of new cases in the past week.

Pakistan reported 22 000 new cases (99 new cases per 1 million population) and 420 new deaths (2 new deaths per 1 million population). New weekly cases have risen since the week of 19 October, when 4 000 cases were reported. This week's new cases and deaths represent a 5% and 17% rise respectively compared to last week. Since the beginning of the pandemic, as of 6 December, Pakistan had conducted 5.7 million COVID-19 tests, with a current positivity rate of 7.5%. The Sindh and Punjab Regions account for around 73% of total cases, with around half of current active cases reported from the Sindh Region.

The United Arab Emirates reported 8 500 new cases (850 new cases per 1 million population) and 20 new deaths (2 new deaths per 1 million population). New cases per week have remained above 8 000 since 12 October. The United Arab Emirates is the first country to approve a vaccine produced by Sinopharm, based in China. In the next few weeks, Abu Dhabi is planning to further open the business, tourism and cultural sectors.

Tunisia reported 7 400 new cases (620 new cases per 1 million population) and 310 new deaths (26 new deaths per 1 million population). Similar to the United Arab Emirates, new cases per week have also remained high since the end of September and October, with more than 7 000 new weekly cases reported. Since the beginning of the pandemic, as of 6 December, 480 000 tests have been conducted, with a current positivity rate of 30%. National authorities have announced an extension to the night curfew until the end of the year.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 13 December 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

The number of new cases continued to stabilise for the third consecutive week in the European Region. There was also a decline in reported deaths for the second consecutive week, a decrease of 4% compared to the previous week. The number of new deaths reported this week, particularly in eastern and southern countries of the European Region, exceeded 60 per 1 million, the highest globally. In the past week, some countries have announced initial vaccination in the population, while others are preparing for the introduction of the vaccine. Despite this, it is important that public health and social measures, including hand hygiene, mask wearing, physical distancing and adequate ventilation, along with other measures, continue.

The Russian Federation reported 193 000 new cases (1 300 new cases per 1 million population), the second highest number of cases in the European Region after Turkey, and 3 800 new deaths (26 new deaths per 1 million population). The two most populous cities in the country, Moscow and St Petersburg, together with the Moscow and Nizhny Novgorod regions, are reporting the highest numbers of new cases. Since the first cases on 31 January, over 2.6 million cases and 46 000 deaths have now been reported - the fourth highest global total cases. The number of new cases and new deaths has increased over five-fold since the last week of August, when 33 500 new cases and 700 new deaths were reported. In the past week, 23 tests per 1 000 population were conducted resulting in a test positivity rate of around 6%.

Serbia reported 47 500 new cases (6 800 new cases per 1 million population) and 380 new deaths (55 new deaths per 1 million population). This was a slight decrease in new cases from the previous week during which over 50 000 new cases were reported. The number of cases has rapidly increased since September, when there were around 500 new cases per week. The percentage of COVID-19 tests that are positive has increased from less than 10% in September to over 30% last week during which 19 tests per 1000 population were conducted.

Sweden reported 32 000 new cases (3 200 new cases per 1 million population) and 128 new deaths (13 new deaths per 1 million population). New weekly cases have remained above 30 000 since 9 November. However, there was a substantial decrease in deaths reported this week with a 62% decrease compared to the previous week.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 13 December 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

In the South-East Asia Region, new cases reported (290 000) showed a 13% decline from the previous week and continued the general pattern of decreasing cases since early September. New deaths (4 400) decreased 12% in the past week, following a 3 week increase. Only three out of ten countries in the region (Sri Lanka, Indonesia and Thailand) reported an increase in new cases this week.

While India has consistently reported the highest number of cases and deaths in the Region, declining trends in both have been seen over the past month, with that trend continuing this week. The country reported decreases in both new cases (213 000, a 15% decrease) and new deaths (2 800, a 19% decrease) compared with the previous week. A recent study found that very few deaths were recorded in long-term care facilities across the three western Indian states of Gujarat, Rajasthan and Maharashtra, states that are among some of the most affected by the pandemic. India has conducted over 153 million tests since the start of the pandemic with 4.9 tests per 1000 population conducted in the previous week and a test positivity rate of around 3.2%.

In Indonesia, the trend in increasing new cases and deaths reported in the past 5 weeks, continued last week. While there was a very minor increase in the number of new cases (42 000, a 1% increase), the number of new deaths reported this week increased by 13% (to just over 1 000). In the week ending 6 December just 0.89 tests per 1000 population were conducted with a test positivity rate of 14.2%, suggesting the need to expand testing to ensure all cases are being detected. The highest number of cumulative cases is seen in the provinces of DKI Jakarta, Jawa Timur and Jawa Tengah.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 13 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

Although cases and deaths in the region still continue to account for a very small proportion of the global total, a 13% increase in the number of new weekly cases (45 000) and a 16% increase in new weekly deaths (500) was observed in the past 7 days in the Western Pacific Region. With the exception of a slight decrease last week, this follows an increasing trend over the past six weeks. There are considerable regional differences, with around half of countries reporting decreases and half reporting increases in cases (notably Japan, Malaysia, and the Republic of Korea).

Japan continues to report the highest number of weekly new cases in the Region and this week reported record highs (17 200 cases, 136 new cases per 1 million), following increases over the previous eight weeks. In an effort to reduce increasing cases and demands on healthcare, the Japan Self-Defense Forces (JSDF) have sent health workers to Asahikawa city in Hokkaido Prefecture. Osaka prefecture has also requested additional support in healthcare capacity from the JSDF as it is the second most affected prefecture following Tokyo. In the previous week Japan conducted 1.9 tests per 1000 population with a test positivity rate of over 6%.

This is the fifth consecutive week the Republic of Korea has reported an increase in new cases, reaching the highest total of new weekly cases (5 200). The provinces reporting the highest incidence are Seoul and Gyeonggi-do. As a result of these increases, tighter public health and social measures in the Capital area have been implemented until the end of the year. In the past week, hospital bed shortages in the Seoul area have also been reported, with only 3 out of 62 hospital beds for critically ill patients in Seoul city currently available.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 13 December 2020**

Key weekly updates

Human Rights Day and Universal Health Coverage Day occurred this week. WHO Director-General Dr Tedros said that these days “[are a reminder that as we rebuild from this crisis, we must do so on the foundation of human rights including the right to health.](#)” WHO, through the [UHC Partnership](#), has profiled some successes in promoting UHC in [Assam](#), [Burkina Faso](#) and [Thailand](#).

Dr Tedros highlighted that since its creation, the [ACT Accelerator](#) has served to fast-track the development of rapid diagnostic tools and vaccines and helped to repurpose a common drug to help save lives amidst the pandemic. WHO has facilitated price and volume guarantees for over 120 million new high-quality rapid diagnostic tests and secured 2.9 million treatment courses of dexamethasone for low- and middle-income countries. WHO has also secured manufacturing capacity for one billion vaccine doses through the [COVA facility](#) and helped almost 100 countries carry out a vaccines readiness assessment. However, Dr Tedros highlighted [the need for urgent financial and political action](#) to fully finance the ACT Accelerator and ensure the equitable distribution of scarce assets.

At the [3rd Global Infodemic Management Conference](#) civil society representatives advocated for a community-led approach to halt the spread of the COVID-19 Infodemic.

WHO welcomed the establishment of [the Galien Prize Africa](#), which promotes research, innovation and commercialization in Africa of pharmaceutical, biotechnology and medical diagnostic products. The WHO Director-General highlighted that most African countries have succeeded in preventing or containing widespread community transmission but cautioned that with the concerning increase in cases and deaths in the region all countries must remain vigilant at this critical juncture in the pandemic for Africa.

Together with WHO, the United Nations Foundation and an alliance of the world’s largest youth movements and organizations [launched a new global youth mobilization](#) to invest in and scale up youth-led solutions and engagements in response to COVID-19. Called the “Global Youth Mobilization for Generation Disrupted” the alliance is being led by the [Big 6 Youth Organizations](#).

WHO has published the following documents in the past week:

- [Public health considerations for elections and related activities in the context of the COVID-19 pandemic](#)
- [Evidence to recommendations for COVID-19 vaccines: Evidence framework](#)
- [COVID-19 vaccine introduction and deployment costing tool](#)
- [Checklist to support schools re-opening and preparation for COVID-19 resurgences or similar public health crises](#)

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. Retro-adjustments can also affect the percentage change reported in Table 1, with the percentages reflecting retro-adjustments made over the past week. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 744 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see: [Considerations for implementing and adjusting public health and social measures in the context of COVID-19](#):

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorizations are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

iii “Territories” include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 6 December 2020, 10 am CET

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Global summary

The global incidence of new cases remained very similar to the previous week with just under 4 million new cases reported in the past seven days, while new deaths, globally, increased slightly to over 73 000 new deaths reported. New cases and deaths in the Region of the Americas account for nearly half of all new cases and over one third of all new deaths this week. While new cases remain high in the European Region, new deaths have decreased for a second week. New cases declined in South-East Asia and Eastern Mediterranean regions this week. Deaths decreased in the Eastern Mediterranean Region, and increased in the South-East Asia Region. In the African Region, while both new cases and deaths remain low compared to other regions, there was an increase of 9% in new cases. New deaths have remained stable over the past few weeks. In the Western Pacific Region, cases showed a small decline overall while new deaths increased slightly this week.

As of 7 December there have been over 65.8 million cases and over 1.5 million deaths reported since the start of the pandemic.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 6 December 2020**

**See [data table and figure notes](#). 1.5 m

In the past week, the five countries reporting the highest number of cases were the United States of America (reporting over 1.2 million cases, a 9% increase from the previous week), Brazil (over 295 000 new cases, a 35% increase), India (over 251 000 cases, a 15% decrease), Russian Federation (over 191 000 new cases, a 6% increase) and Italy (over 145 000 new cases, a 21% decrease).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

Figure 2. COVID-19 cases per 1 million population reported in the last seven days by countries, territories and areas, 30 November through 6 December 2020**

****See data, table and figure notes**

Situation by WHO Region

African Region

In the past seven days, over 53 000 new cases were reported in the African Region, a 9% increase compared to the previous week, while deaths remained similar to last week's at just under 1000 new reported deaths (Figure 3). South Africa continues to account for the greatest proportion (48%) of new weekly cases in the Region. In the past seven days, the highest number of new cases was reported from South Africa (25 310 new cases, 427 new cases per 1 million population), Algeria (6290 new cases, 143 new cases per 1 million population), Kenya (5379 new cases, 100 per 1 million population), Ethiopia (3810 new cases, 33 new cases per 1 million population) and Uganda (2244 new cases, 49 per 1 million population).

Over the past month, Kenya has reported its highest weekly cases and deaths. However, in the past week these numbers have declined by 13% and 8%, respectively, for both new cases and deaths. Case totals in the country have reached nearly 88 000 since the start of the pandemic and, with fatalities only being reported for hospital deaths, it is likely that cumulative deaths are being underreported. A study in July reported that for a country of 51 million people, there are only 537 Intensive Care Unit (ICU) beds and 256 ventilators. Nearly 75% of Kenya's ICU beds are in Nairobi and Mombasa. Thus far Kenya has conducted nearly 886 000 tests with a testing rate of 1.2 per 1000 population in the last week and a test positivity rate of 10%.

Cases in Nigeria have increased by 46% in the past seven days, the highest weekly case count reported since August. In the past seven days, 22 of the 37 states in Nigeria have reported new cases with the highest case numbers being reported in the states of Lagos, Federal Capital Territory, Plateau, Oyo and Kaduna. In a country of over 206 million persons, Nigeria has conducted over 803 000 tests throughout the pandemic. In the last reporting week, it had a testing rate of 0.17 per 1000 population and a test positivity rate of 4.6%. Additionally, while the volume of in-bound international travel in the past week has remained within its normal parameters, the number of travelers with a positive result after seven days has increased by 68% (from 48 to 81).

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 6 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

In the Region of the Americas, the weekly number of new cases reached 1 845 816 this week with 26 624 new deaths, accounting for 12% and 18% increases compared to the previous week, respectively (Figure 4). The United States of America accounted for 68% of all new cases reported in the past week in the Region. The highest new case and deaths counts were reported in the United States of America (1 251 632 new cases, 3781 new cases per 1 million), Brazil (295 618 new cases, 1391 new cases per 1 million), Mexico (66 095 new cases, 513 new cases per 1 million), Columbia (62 097 new cases, 1220 new cases per 1 million) and Argentina (47 354 new cases, 1048 new cases per 1 million).

In Brazil, a 35% increase in cases was observed in the past week, with 295 618 new cases (1391 cases per 1 million population), which was the highest number reported since mid-August. Upwards trends are being observed in all five regions, and to date, the Southeast Region, which includes the state of Sao Paulo, has reported the highest number of cumulative cases and deaths, followed by the Northeast Region. The number of new deaths was 3990, a 19% increase compared to the previous week. On 1 December, the government of Paraná in southern Brazil, which borders Paraguay and Argentina, introduced a night curfew.

In Mexico, 66 095 new cases (513 cases per 1 million population) were reported in the past week, a 2% increase compared to the previous week and the highest weekly case count since the beginning of the pandemic. There were 3990 new deaths reported, similar levels to the previous week. The government is urging citizens to stay home, and is planning to add hospital beds, medical equipment, and increase the number of doctors and nurses ahead of the holiday season.

The number of new cases in Canada continues to increase with 43 505 reported (1153 cases per 1 million population), a 13% increase from the previous week reaching the highest weekly number since the beginning of the pandemic. Six hundred and two new deaths were reported in the past week, a 7% increase compared to the previous week. In Manitoba province, which reported the fifth highest number of COVID-19 cases in Canada, outbreaks have been reported in a children's daycare center, at a hospital and at a care home in recent weeks. The province of Quebec plans to prohibit gatherings over the holidays in the maximum alert "red zones", which covers most of the state, as a result of the recent upward trend in cases.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 6 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

For the second consecutive week, both new cases and new deaths have declined. The Eastern Mediterranean Region reported over 240 000 new cases and over 5000 new deaths, reflecting a reduction of 2% and 12% respectively compared to the previous week (Figure 5). Increases in both new weekly cases and new weekly deaths were reported in Afghanistan, Egypt, occupied Palestinian territory, Oman and Somalia. The highest number of new cases were reported from the Islamic Republic of Iran (93 187 new cases, 1109 new cases per 1 million), Morocco (27 050 new cases, 733 new cases per 1 million), Jordan (26 804 new cases, 2627 new cases per 1 million), Pakistan (20 835 new cases, 94 new cases per 1 million) and Iraq (13 699 new cases, 341 new cases per 1 million).

In Lebanon, over 10 000 new cases (1500 per 1 million population) were reported in the past week. Since cases peaked in the beginning of November, small weekly decreases in new cases have been reported. Ninety-nine new deaths were reported this week compared to the 97 reported in the previous week. National health authorities stated on 3 December that ICUs for COVID-19 patients remain at critical capacity. Before the strengthening of public health and social measures (PHSM) came into effect in mid-November, the occupancy of ICU beds ranged between 80 and 90%. As an effect of these measures being implemented, occupancy has declined to the range of 65 to 70%. Despite the high occupancy in healthcare facilities, Lebanon has seen a decreasing trend in new cases and the country is gradually relaxing PHSM by reopening restaurants, postponing curfews and returning to face-to-face classes in some schools.

Morocco continued to show a decreasing trend in the past week, reporting a decrease of 6% in weekly new cases and 8% in weekly new deaths compared to the figures in the past week. The country reported over 27 000 new cases (733 cases per 1 million population) and over 400 new deaths (12 deaths per 1 million population). Since its peak of cases in mid-November, Morocco has shown a decreasing trend in cases for three consecutive weeks. National health authorities inaugurated a new field hospital in the region of Souss-Massa this week and established new hospital projects for treating COVID-19 patients planned for 2021 in the region of Rabat-Salé-Kenitra.

Since mid-October, cases in Egypt have increased. In the current week, the country reported over 2800 new cases, a 13% increase compared to the past week (28 cases per 1 million population). As Egypt experiences a resurgence in COVID-19 infections, the country is strengthening public health and social measures by reducing the working hours for shops and limiting the number of employees and workers in government offices.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 6 December 2020**

**See data, table and figure notes

European Region

The number of new cases in the European Region remains high with over 1.4 million new cases reported in the past week (Figure 6). However, the number of new cases has declined again, in line with the past four weeks, down 10% in comparison to the last seven days. While deaths also decreased in the Region in the past seven days, there were still almost 35 200 deaths reported. Despite the observed reductions, the European Region continues to account for the second highest number of new cases and deaths globally (37% and 48% respectively). Last week, the countries reporting the highest number of new cases were the Russian Federation (191 454 new cases, 1312 new cases per 1 million population), Italy (145 459 new cases, 2406 new cases per 1 million population), Germany (128 622 new cases, 1535 new cases per 1 million population) and the United Kingdom (100 799 new cases, 1485 per 1 million population).

In Germany, the weekly number of new cases have remained relatively unchanged compared to the previous week (3% increase), while the number of deaths has increased by 26%. An increase in both cases and deaths was seen in early October, which then seemed to have plateaued in the latter half of November. While the incidence in younger ages remains stable, it continues to increase in older age groups with an incidence of cases of 128 per 100 000 population in those aged 60 years and over. The distribution of cases and deaths varies across the country with the state of North-Rhine Westphalia consistently reporting the highest number of cases, while deaths are highest in Bavaria (30.9 per 100 000 population).

The United Kingdom continues to report high numbers of new cases and deaths, although overall incidence have decreased for the past three weeks. The country introduced tighter public health and social measures on 5 November. It has conducted nearly 39 million tests since the start of the pandemic. In the past week, the testing rate has been 29 tests per 1000 population with a test positivity rate of 5.8%. On 2 December, the United Kingdom became the first country to approve Pfizer/BioNTech's COVID-19 vaccine, with the first doses to be administered on 8 December. Vaccines will be available to about 70 hospital hubs across the country, and provided first to those aged over 80 years and health care workers.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 6 December 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

In the South-East Asia Region, new cases reported last week declined 10% compared to the previous week (332 396 new cases, 164 new cases per 1 million population), although new weekly deaths showed a slight increase of 2% compared to the previous week (5004 new deaths, 2 new deaths per 1 million population) (Figure 7). The trends in cases and deaths are still largely driven by India, which reported 76% and 70% of new weekly cases and deaths respectively in the Region. A decrease in new weekly cases was reported in India, Nepal and the Maldives, whereas an increase was reported from Bhutan, Indonesia, Myanmar, Sri Lanka and Thailand. The highest number of new cases were reported from India (251 303 new cases, 182 new cases per 1 million), Indonesia (41 708 new cases, 152 new cases per 1 million) and Bangladesh (15 260 new cases, 93 new cases per 1 million).

In Nepal, over 9000 new cases (314 per 1 million population) were reported in the past week, a significant decrease of 24% compared to the previous week. In addition, the number of new deaths decreased by 17%, to 123 new deaths (4 deaths per 1 million population). As of 2 December, 77% of cases were reported from three provinces, Province 1, Bagmati province and Lumbini province. National authorities inaugurated 5 provincial infectious diseases hospitals and 309 basic hospitals at the municipal level across the country. In addition, health authorities are working with Kathmandu Municipality, one of the hardest hit areas, to institutionalize community based active surveillance and testing.

In Bangladesh, new weekly cases and deaths remained at similar levels as the previous week, with over 15 000 new cases (93 new cases per 1 million population) and 227 new deaths (1 death per 1 million population) reported in this week. As of 30 November, the bed occupancy rate for general beds and ICUs were 17.4% and 56.2% respectively, according to national health authorities. Moreover, on 5 December, the country started a new testing strategy, introducing the antigen rapid detection test (Antigen-RDT) in 10 of the 64 districts (Jashore, Brahmanbaria, Gaibandha, Joyupurhat, Madaripur, Meherpur, Munshiganj, Panchagarh, Patuakhali, and Sylhet). Among the samples tested, the proportion of infection detected by Antigen-RDT was 26.5%. The country will be gradually expanding antigen-based testing in areas where PCR testing is currently not implemented.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 6 December 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

Last week, in the Western Pacific Region, the weekly incidence of new cases was 40 039, with 461 new deaths, accounting for a 1% decrease in cases and a 4% increase in deaths compared to the previous week (Figure 8). Countries including the Republic of Korea and China reported an upward trend in weekly new cases, while countries including Malaysia, Guam and Mongolia reported a downward trend compared to the previous week. The highest new case and deaths counts were reported in Japan (15 445 new cases, 122 new cases per 1 million), Philippines (10 272 new cases, 94 new cases per 1 million) and Malaysia (8183 new cases, 253 new cases per 1 million).

In Malaysia, 8183 new weekly cases were reported, a 14% decrease compared to the previous week, but the levels continue to remain high since the rise of cases in September. The number of new weekly deaths reported were 26, an 18% increase compared to the previous week, but overall the trend continues to decline since death counts peaked in mid- to late October. Sabah state has reported the highest number of cumulative cases, followed by Selangor, Kuala Lumpur and Negeri Sembilan states. Among the new cases reported in the past week, there were cases linked to clusters in prisons and temporary detention centers in Kedah, Selangor, Negeri Sembilan, Sabah and Penang states. In addition to correctional facilities, clusters have also been identified in construction sites, factories and other workplaces, as well as in family settings.

China reported 831 cases (1 per 1 million population) in the past week, a 22% increase compared to the previous week, though cases remain at low levels. New weekly cases last exceeded 800 in the week commencing 27 July. Three deaths were reported in the pas week.

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

At the United Nations General Assembly Special Session, WHO Director-General Dr Tedros Adhanom Ghebreyesus delivered four key areas in which leaders can invest to end the pandemic and build the post-pandemic world; [vaccines, preparedness to prevent the next pandemic, health as the foundation of peace and prosperity and multilateralism to safeguard our common future.](#)

Dr Tedros thanked donors for answering the initial call for funding the Gavi COVAX Advanced Market Commitment target of US \$2 billion in 2020, and put forth WHO's [unwavering commitment to equitable, timely and fair access to all the tools that can serve to mitigate and end the pandemic.](#) He reminded all that the pandemic has ["a long a way to run and decisions made by leaders and citizens in the coming days will determine both the course of the virus in the short term and when this pandemic will ultimately end."](#)

At the release of the study on the global estimates of the need for rehabilitation, Dr Tedros highlighted the importance of the fight to restore [full health and dignity](#) for those affected by infectious disease including COVID-19, as well as noncommunicable disease, accidents, conflicts and many other health issues.

Water, sanitation and hygiene is a first line of defense against COVID-19 and many other diseases. In the opening remarks of the discussion between health, water and finance ministers, Dr Tedros emphasized that ["investments in health – including water, sanitation, and hygiene – are the necessary foundation for productive, resilient and stable economies."](#)

On World AIDS Day, Dr Tedros highlighted how ["health and community workers who provide the bulk of HIV services now find themselves battling not just HIV, but COVID-19"](#) and that preventing and testing HIV must reach groups in need by employing a people-centric approach with comprehensive and integrated health services.

As COVID-19 vaccines finally become within reach, [vaccine acceptance is the next hurdle](#). People's behaviour for vaccine uptake is driven by an enabling environment for people to easily access affordable vaccines, harnessing social influences including from community leaders, and increasing individual motivation through open and transparent communication about the vaccine.

[WHO launched a youth council](#) to advise the Director-General on global health and development issues that impact young people. These challenges include the long-term consequences of the pandemic which will shape the world they live and work in for decades to come.

WHO has published the following documents:

- [Mask use in the context of COVID-19;](#)
- [Health workforce policy and management in the context of the COVID-19 pandemic response;](#)
- [A prospective cohort study investigating maternal, pregnancy and neonatal outcomes for women and neonates infected with SARS-CoV-2;](#)

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases. Differences are to be expected between information products published by WHO, national public health authorities, and other sources. Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Global totals include 741 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Excludes countries, territories, and areas that have never reported a confirmed COVID-19 case.

ⁱⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas. For further information, please see:

[Considerations for implementing and adjusting public health and social measures in the context of COVID-19:](#)

- No (active) cases: No new cases detected for at least 28 days (two times the maximum incubation period), in the presence of a robust surveillance system. This implies a near-zero risk of infection for the general population.
- Imported / Sporadic cases: Cases detected in the past 14 days are all imported, sporadic (e.g. laboratory acquired or zoonotic) or are all linked to imported/sporadic cases, and there are no clear signals of further locally acquired transmission. This implies minimal risk of infection for the general population.
- Clusters of cases: Cases detected in the past 14 days are predominantly limited to well-defined clusters that are not directly linked to imported cases, but which are all linked by time, geographic location and common exposures. It is assumed that there are a number of unidentified cases in the area. This implies a low risk of infection to others in the wider community if exposure to these clusters is avoided.
- Community transmission: Which encompasses a range of levels from low to very high incidence, as described below and informed by a series of indicators described in the aforementioned guidance. As these subcategorization are not currently collated at the global level, but rather intended for use by national and sub-national public health authorities for local decision-making, community transmission has not been disaggregated in this information product.
 - CT1: Low incidence of locally acquired, widely dispersed cases detected in the past 14 days, with many of the cases not linked to specific clusters; transmission may be focused in certain population sub-groups. Low risk of infection for the general population.
 - CT2: Moderate incidence of locally acquired, widely dispersed cases detected in the past 14 days; transmission less focused in certain population sub-groups. Moderate risk of infection for the general population.
 - CT3: High incidence of locally acquired, widely dispersed cases in the past 14 days; transmission widespread and not focused in population sub-groups. High risk of infection for the general population.
 - CT4: Very high incidence of locally acquired, widely dispersed cases in the past 14 days. Very high risk of infection for the general population.
- Pending: transmission classification has not been reported to WHO.

ⁱⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 29 November 2020, 10 am CET

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Global summary

In the past week, global case incidence remained high at approximately 4 million new cases, although a slight downward trend was observed (Figure 1). Weekly deaths, however, continued to rise, with over 69 000 new deaths reported globally. The Region of the Americas was the largest contributor for new weekly cases last week. Although the European Region reported a continued decrease in new weekly cases, it still accounts for the second greatest proportion of new weekly cases, while deaths rates have continued to increase and accounted for approximately half of the new global deaths in the past week. The Eastern Mediterranean Region registered a slight decline in both cases and deaths last week, after four months of continued increases. Relatively small increases were reported from the African and South-East Asia Regions, and more substantively from the Western Pacific Region last week.

As of 29 November, there have been over 61.8 million cases and over 1.4 million deaths reported globally since the start of the pandemic.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 29 November 2020**

**See [data table](#) and [figure notes](#).

In the past week, the five countries reporting the highest number of cases were the United States of America (reporting over 1.1 million cases, a 0.3% increase from the previous week), India (over 297 000 cases, a 6% increase), Brazil (over 218 000 new cases, a 4% increase), Italy (over 184 000 new cases, a 22% decrease) and Russian Federation (over 179 000 new cases, a 10% increase).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

**See data, table and figure notes

Situation by WHO Region

African Region

The African Region reported about 48 000 new cases and just under 1000 new deaths last week; a 3% and -10% change from the previous week, respectively (Figure 3). The highest number of new cases and deaths were reported from South Africa (19 730 new cases, 333 new cases per 1 million), Algeria (7438 new cases, 170 new cases per 1 million), Kenya (6201 new cases, 115 new cases per 1 million), Ethiopia (3578 new cases, 31 new cases per 1 million), and Uganda (2277 new cases, 50 new cases per 1 million), which collectively account for 81% of all new cases in the Region.

For the past three weeks, cases in South Africa have increased by over 20% week-on-week, and last week 19 730 new cases were reported (3500 more than the previous week). The rise in new cases in the Western Cape (including in Cape Town) and Eastern Cape provinces is a cause for concern. As of 30 November, Gauteng, the Western Cape, the Eastern Cape, and Kwa-Zulu-Natal provinces have reported 79% of total cumulative cases.

Ethiopia reported 3578 new cases (31 new cases per 1 million) and 59 deaths (0.5 new deaths per 1 million) in the past week. The number of new cases being reported from Ethiopia has fallen considerably since a peak at the end of August when there were over 10 000 new cases per week. This week the number of new cases rose by 18%, while new deaths fell by 17% from the previous week. The UN refugee agency (UNHCR) has [warned that a full-scale humanitarian crisis is unfolding](#) as thousands of refugees in the Tigray region seek safety in eastern Sudan. At the 70th Session of the WHO Regional Committee for Africa held last week, [Ethiopia's Minister of Health](#) highlighted the need to continue to be vigilant in COVID-19 testing, isolation and treatment, and maintaining strong communication on public health and social measures.

Cameroon reported 589 new cases (22 new cases per 1 million) and 2 new deaths (0.1 new deaths per 1 million) in the past week. Since first declaring cases on 6 March, new cases rose to peak at around 2000 cases per week at the end of June and in early July. However, the number of new cases declined in July and have averaged below 400 per week since early August. For the past two weeks cases have risen above this average, with 836 new cases two weeks ago and nearly 600 cases reported this last week. Last week [UNHCR warned](#) that as the pandemic continues, a lethal mix of state at home orders, deepening poverty and economic duress is unleashing a wave of violence against refugee, displaced and stateless women and girls. UNHCR report that in North-West and South-West Cameroon where the security situation remains volatile, a staggering 26% of gender-based violence incidents logged since the onset of the pandemic relate to children.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 29 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Region of the Americas reported over 1.6 million new cases and 22 000 new deaths, a small increase of 3% and 2%, respectively (Figure 4). The highest number of new cases and deaths were reported from the United States of America (1.15 million new cases, 3476 new cases per 1 million), Brazil (218 000 new cases, 1026 new cases per 1 million), Mexico (64 000 new cases, 502 new cases per 1 million), Colombia (57 000 new cases, 1122 new cases per 1 million), and Argentina (48 000 new cases, 1067 new cases per 1 million). These five countries account for 93% of all new cases in the Region.

Colombia reported the fourth-highest number of new cases in the Region, with 57 000 cases (1122 new cases per 1 million). The number of new deaths increased by 2% from previous week to 1285 new deaths (25.3 new deaths per 1 million). Since the pandemic started, Colombia has seen at least one prominent peak in case incidence in August during which almost 78 000 cases per week were reported, followed by a moderate decline; however, the country has sustained over 50 000 new cases per week since early October. Bogotá, Amazonas, and Barranquilla have reported the highest case incidence. Among active cases, 70% are at home, 26% in general hospitalization and 3% in intensive care units (ICUs). Men account for 64% of cases, and 77% of those who have died were aged 60 years and over. Colombia has extended its state of emergency by three months.

Peru reported 12 000 new cases (371 new cases per 1 million) and 355 new deaths (10.8 new deaths per 1 million); decreases of 9% and 6%, respectively from the previous week. Since new cases peaked in the week of 17 August at almost 60 000 cases, Peru has observed a consistent decline in cases. Preliminary results of a seroprevalence study in the capital, Lima suggest that around 35% of the population has been infected. To prepare for vaccination activities, 10 000 members of the armed forces are being trained to support immunization campaigns.

Chile reported 9798 new cases (513 new cases per 1 million) and 292 new deaths (15.3 new deaths per 1 million). New cases in Chile peaked in the week of 15 June with 69 000 cases. Since early August, between 9000–13 000 cases have been reported weekly, with an overall slow rate of decline. The Minister of Health reported that the numbers of hospitalized patients and patients admitted to ICU are also gradually declining. Magallanes Region has reported the highest cumulative incidence rates, followed by the Metropolitan, and Arica and Parinacota regions. The Ministry of Health has expressed concerns over increases in some southern regions, such as Los Ríos, Magallanes and La Araucanía. Chile reports that 5 million tests have been conducted, around 1 million tests per month. The Arturo Merino Benítez airport was opened for foreigners last week. An upcoming election was scheduled for 29 November, although people with COVID-19 were not allowed to go to the polls.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 29 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

After fifteen weeks of steady increases in weekly cases, both new cases (248 000) and new deaths (5800) have shown a slight reduction in the Eastern Mediterranean Region, of 1% and 8% respectively compared to the previous week (Figure 5). The highest number of new cases were reported from the Islamic Republic of Iran (94 500 new cases, 1125 new cases per 1 million), Jordan (32 500 new cases, 3200 new cases per 1 million), Morocco (29 000 new cases, 780 new cases per 1 million), Pakistan (21 000 new cases, 94 new cases per 1 million), and Iraq (15 000 new cases, 380 new cases per 1 million).

In the occupied Palestinian territory, including East Jerusalem, reported cases and deaths both increased by 43% in the past week, with over 12 000 new cases (2368 cases per 1 million) and 93 new deaths (18.2 new deaths per 1 million) reported. This represents the highest number of new cases reported per week in the territory since the outbreak began. The proportion of positive tests has increased slightly over the last three weeks along with an increase in the number of total tests conducted. In the Gaza strip, the current testing strategy is limited to symptomatic patients and their contacts, and a 5% COVID-19 infection rate among health workers. Health services continue to operate with 50% of beds in hospitals and 78% of ICU capacity occupied by COVID-19 patients.

The Islamic Republic of Iran continues to report the highest number of incident cases in the Region. The country has experienced an increasing trend in newly reported cases since the end of August with a 3% increase to 94 000 new cases (1124 cases per 1 million) in the last week. During this period, the number of weekly new deaths decreased by 4% to 3159 deaths (38 deaths per 1 million). As Iran approaches the 1 million case mark in the coming week, the country is strengthening public health and social measures to curb this trend by introducing curfews and partial movement restrictions based on the number of confirmed COVID-19 hospitalizations in respective cities and counties. COVID-19 PCR testing activity has substantially increased from an average of 6 samples/100,000 population/week during August, to 27 samples/100,000/week in the past 4 weeks (totaling over 6 million tests to date); however, positivity rates have also increased over the same period, from 10% to 32% in the past week.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 29 November 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

In the European Region, the number of new cases has been decreasing for three consecutive weeks, since its peak in the first week of November. In the past week, the number of new cases reported declined by 13% to over 1.5 million (Figure 6). Despite this reduction, the Region still accounts for 40% of new global cases and 50% of new global deaths as almost half of the countries within the region continue to show an increasing trend. Last week alone, over 35 000 new deaths were reported from the Region, bringing cumulative deaths to 412 000. The highest number of new cases were reported from Italy (184 000 new cases, 3000 new cases per 1 million), Russian Federation (180 000 new cases, 1200 new cases per 1 million), Poland (130 000 new cases, 3438 new cases per 1 million), Germany (124 000 new cases, 1500 new cases per 1 million), and the United Kingdom (112 000 new cases, 1647 new cases per 1 million).

In Turkey, upward trends in both cases and deaths have continued over the past week, with over 47 000 new cases (560 new cases per 1 million) and just over 1150 new deaths (14 new deaths per 1 million) reported. The country saw a 58% increase in new cases in the past week, with rising numbers previously seen mainly in Istanbul, Izmir and Bursa having now spread throughout the country. There have been concerted efforts to increase testing capacity following an upward trend in reported cases during the summer holiday period. To date, over 18.2 million tests have been conducted with a 3% positivity rate in the past week.

Serbia has reported a steady increase in the weekly number of cases and deaths since October. In the past week, 46 910 new cases (6700 new cases per 1 million) and 300 new deaths (45 new deaths per 1 million population) were reported. The country has conducted over 1.7 million tests to date, including around 137 000 people tested in the past week (20 tests/1000 population/week), of which 34% were positive. With over 7200 patients hospitalized and more than 250 on ventilation support at the end of last week, a clinic in the country will be converted into a COVID-19 hospital to provide intensive care and oxygen support to cope with the increase in number of cases requiring clinical care.

In Greece, after several weeks of an upward trend, cases have decreased by 27% with 12 913 new cases (1239 new cases per 1 million) reported. Whereas, a steep increase in the number of deaths continues, with 696 new deaths (67 new deaths per 1 million) in the past week. This number accounts for one third of the total deaths reported since the beginning of the outbreak. As the current situation is challenging the national health system, plans are underway to strengthen it at the national level and in the most affected areas in Thessaloniki, which is located in northern Greece, by ensuring that every patient receives the health care needed though hiring more health workers and increasing ICU capacity.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 29 November 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

In the South-East Asia Region, new weekly cases remained at similar levels as the previous four weeks with 371 180 cases reported in the past week. The trend in cases is largely driven by the number of cases in India, which reported 80% of new weekly cases in the Region. A decrease in new weekly cases was observed in Myanmar, Sri Lanka and the Maldives, whereas an increase was reported from Indonesia, Nepal, Thailand and Bhutan. There were 4888 deaths reported from seven countries in the past week, a 4% increase compared to the previous week. The highest number of new cases were reported from India (297 000 new cases, 215 new cases per 1 million), Indonesia (35 000 new cases, 127 new cases per 1 million), Bangladesh (15 000 new cases, 93 new cases per 1 million), Nepal (12 000 new cases, 415 new cases per 1 million) and Myanmar (8 800 new cases, 161 new cases per 1 million).

In India, 297 113 new cases (215 per 1 million population) were reported in the past week. Since cases peaked in the week commencing 14 September, weekly decreases in new cases have continued. There were 3469 deaths reported in the past week, a 3% decrease compared to the previous week, but the number of weekly deaths has remained relatively stable since late October. As of 27 November, 70% of active cases were reported from eight states and union territories, including Maharashtra, Kerala, Delhi, Rajasthan and Uttar Pradesh. Maharashtra has been the most affected state in terms of the number of cases and deaths reported. In Delhi, the number of new cases has decreased from 46 876 cases in the week commencing 9 November to 36 785 cases in the past week. State governments including Himachal Pradesh, Madhya Pradesh, Gujarat and Rajasthan have implemented night curfew in selected areas.

In Indonesia, 34 691 new cases (127 per 1 million population) were reported in the past week, bringing the cumulative cases to over half a million cases. A total of 872 new deaths were reported, a 39% increase compared to the previous week. Cases have been confirmed in 505 out of 514 districts and municipalities across all 34 provinces. As of 22 November, the test positivity rate in Indonesia was 14%. In Jakarta, local authorities extended public health and social measures for two additional weeks. In 98 referral hospitals in Jakarta, the average bed occupancy has increased from 56% to 73%, and the ICU occupancy has increased from 60% to 70% (591 of 841 beds occupied) in the past two weeks.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 29 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

In the past week, the number of new cases reported in the Western Pacific Region increased by 12% with 40 550 cases, continuing the increase since the beginning of November (Figure 8). The number of weekly cases is lower than the highest peak observed in the Region in the week commencing 3 August. The number of deaths in the past week remained at similar levels compared to the previous two weeks with 445 deaths reported from eight countries including the Philippines and Japan which together comprised 87% of all deaths. The highest number of new cases were reported from Japan (14 500 new cases, 114 new cases per 1 million), Philippines (11 000 new cases, 100 new cases per 1 million), Malaysia (9500 new cases, 293 new cases per 1 million), Republic of Korea (3000 new cases, 60 new cases per 1 million) and French Polynesia (1100 new cases, 4000 new cases per 1 million).

The Philippines reported 10 945 cases (100 cases per 1 million) in the past week; a similar level to the previous week. The overall trend shows a gradual decrease since its peak in late July to early August. The country reported 253 new deaths in the past week, a 12% decrease compared to the previous week, although the Philippines has reported the highest cumulative deaths in the Region with 8333 deaths. As of 25 November, 55% of cumulative cases were male, and the most affected age group was 20 to 29 years (27%) followed by 30 to 39 years (24%). Out of 8215 confirmed deaths, 60% were male, with the most affected age group aged over 70 (34.5%) followed by 60 to 69 years (27.3%). The National Capital Region, which surrounds Manila, has reported 46% of cumulative cases, followed by Calabarzon Region (18%) in the south-east of Manila. National authorities have conditionally approved ending restrictions on Filipino healthcare workers to take up employment outside of the Philippines and are developing a contingency plan to rapidly respond to a possible surge following the upcoming holiday season.

The Republic of Korea reported 3091 new weekly cases (60 cases per 1 million), a sharp 41% increase compared to the previous week, reaching the highest weekly case count since early March. A total of 18 new weekly deaths were reported; in comparison, less than 20 deaths/week have been reported since late September. Sources of infections have diversified since the start of the pandemic, and younger groups are now at the center of the spread. Clusters have been traced to military facilities, educational institutions, sporting facilities, healthcare facilities, gatherings among friends, among others. In Seoul, the five-tier physical-distancing rules have been raised to the third-highest level amid rising cases in the metropolitan area. The government urged students to stop attending “cram schools” and private lessons ahead of college entrance exams in early December.

In French Polynesia, 1118 new cases were reported in the past week, a 12% decrease compared to the previous week, continuing a downward trend since the week commencing 9 November. Incidence is decreasing in Tahiti and other islands. Ten new deaths were reported in the past week, similar to the the previous week. While there are currently no national movement restrictions implemented, a curfew was introduced in October and there are inter-island movement restrictions in place.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 29 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- With the latest positive news from vaccine trials “there is now [real hope](#) that vaccines in combination with other tried and tested public health measures will help to end the pandemic” said WHO Director-General Dr Tedros last week. WHO has updated the draft [landscape of COVID-19 candidate vaccines](#), which shows that there are 49 candidate vaccines in clinical evaluation, 11 of which are at phase 3 evaluation. The urgency with which vaccines have been developed must be matched by the same urgency to distribute them fairly. Only a fundamental change in funding and approach will realize the full promise of the ACT Accelerator. US\$ 4.3 billion is needed immediately to support the mass procurement and delivery of vaccines, tests and treatments. A further US\$ 23.8 billion will be needed next year.
- At Friday’s [media briefing](#), Dr Tedros reminded people that even after vaccines are available, testing will continue to play a vital role for controlling the pandemic. Testing is at the heart of the response; it shows where the virus is. It must be strategic, in support of clear public health objectives, and based on a country’s transmission scenario.
- Today, the world celebrates [World AIDS day 2020](#) and WHO is calling on global leaders and citizens to rally for “global solidarity” to overcome the challenges posed by COVID-19 on the HIV response. In 2019, there were still 38 million people living with HIV infection. One in five people living with HIV were not aware of their infection and one in 3 people receiving HIV treatment experienced disruption. The COVID-19 pandemic has added to this disruption.
- Up to 5 million deaths a year could be averted if the global population was more active. At a time when many people are home bound due to COVID-19, new [WHO Guidelines on physical activity and sedentary behaviour](#), emphasize that everyone, of all ages and abilities, can be physically active and that every type of movement counts.
- Under the COVID-19 pandemic restrictions, many families have become the sole providers of the nurturing care required for young children’s development. While much is unknown about the pandemic’s impact on children’s development, early childhood development (ECD) data collected before the start of pandemic will provide countries with useful baselines to assess the potential effects of health and societal disruptions on young children and their families in the years to come. In order to track global progress on ECD, WHO, UNICEF and partners last week [launched](#) new expanded 2020 ECD [Countdown to 2030](#) country profiles.
- WHO has published [a checklist for countries to use to assess health service capacity](#). It allows for a rapid determination of current capacities of hospitals to respond to the COVID-19 pandemic and to identify gaps and major areas that require investment and action for the development of hospital readiness improvement plans.
- The COVID-19 pandemic is having a large-scale impact on international travel and trade, particularly in the aviation sector. WHO is conducting systematic reviews to synthesize available data and has published a [document](#) that describes the process that WHO will undertake.

Table 2. COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, and WHO Region, as of 29 November 2020**

Reporting Country/Territory/Area	New cases in last 7 days	Cumulative cases	Cumulative cases per 1 million population	New deaths in last 7 days	Cumulative deaths	Cumulative deaths per 1 million population	Transmission classification

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Global totals include 741 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 22 November 2020, 10 am CET

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

This past week, the global acceleration in case incidence has slowed down, with around 4 million new cases reported; however, death rates continue to increase with over 67 000 new deaths reported (Figure 1). The European and South East Asia Regions continued downward trends in weekly cases; however, the European Region remains the largest contributor to new cases and new deaths in the past 7 days. The Region of the Americas reported increases in both new cases and new deaths and the Region continues to account for the greatest proportion of cumulative cases and deaths. While cases numbers remain relatively low, the African Region reported the highest increase in new cases (15%) and deaths (30%) this week. The Eastern Mediterranean and Western Pacific regions also reported an increase in new cases and deaths this week.

As of 22 November there have been over 57.8 million cases and 1.3 million deaths reported globally since the start of the pandemic.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 22 November 2020**

**See [data table and figure notes](#).

In the past week, the five countries reporting the highest number of cases were the United States of America (reporting over 1.1 million cases, a 14% increase from the previous week), India (over 280 000 cases,

an 8% decrease), Italy (over 230 000 new cases, a 3% decrease), Brazil (over 200 000 new cases, a 17% increase) and France (over 170 000 new cases, a 16% decrease).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

Figure 2. COVID-19 cases per 1 million population reported in the last seven days by countries, territories and areas, 16 November through 22 November 2020**

**See data, table and figure notes

Situation by WHO Region

African Region

In the Region of the Americas, the weekly incidence of new cases reached over 47 000 this week with around 1000 new deaths reported, accounting for 15% and 30% relative increases when compared to the previous week, respectively (Figure 3). The highest new case and death counts were reported in South Africa, Algeria and Kenya.

In Rwanda this week, cases have increased by 25%, with 226 new cases (17.4 cases per 1 million population) reported. Local authorities are enhancing preventative measures in prisons and detention centres following three outbreaks reported in Kigali, Southern and Eastern provinces.

In Zimbabwe, 334 new cases (22.5 cases per 1 million population) were reported this week, with a gradual increase being observed in recent weeks after an initial wave of cases earlier this year. In Matabeleland Northern Province in the North West of the country, there have been reports of a cluster of confirmed cases affecting approximately 100 students at a boarding school, resulting in the closure of the school. Overall, the country has reported over 9 000 confirmed cases and nearly 300 deaths. The characteristics of the cases show most cases (57%) occur in those aged 20-40 years with a greater proportion of females in older age groups. Deaths are largely occurring in those aged 40-80 years and males account for a greater percentage of deaths in these age groups.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 22 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

In the Region of the Americas, the weekly incidence of new cases reached over 1.6 million this week with over 22 000 new deaths reported, accounting for 11% and 15% relative increases when compared to the previous week (Figure 4). The majority of these were reported from the United States of America, with over 1.1 million new cases (9918 cases per 1 million population), followed by Brazil and Mexico.

Cases in the United States of America continue to rise, showing a 14% increase in the past 7 days, while deaths increased by 23%. The three states reporting the highest number of cases were Illinois, Texas and California. With the Thanksgiving holiday on 26 November, many states are implementing additional public health and social measures, and the United States Centres for Disease Control and Prevention have discouraged domestic travel. Nonetheless, the Transportation Security Administration (TSA) screened more than 2 million air passengers on 20 and 21 November, in the two days after the federal government issued a travel warning and it is estimated that some 50 million Americans may be travelling this Thanksgiving.

On the island of Puerto Rico, relatively low levels of transmission have been sustained over several months with 4600 new cases (91 cases per 1 million population) reported last week. However, weekly deaths have trended upwards in recent weeks, from a low of 26 new deaths/week observed in last October, to 90 new deaths reported last week. The highest numbers of cases in the country have been reported in the Metro, Bayamón and Caguas health regions. Women account for a slightly higher proportion of cases (54%), with an overall median age of 41.5 years.

While Argentina currently accounts for the third-highest number of weekly cases (over 62 000 new cases, 1745 cases per 1 million population) and deaths (around 3 200), both new cases and new deaths have been trending downwards since mid-October. There has however, been a slight increase in cases in eight neighborhoods of the Buenos Aires metropolitan area (Balverna, Boca, Colegiales, Contitucion, Nunez, Palermo, Parque Chacabuco and Vila Urquiza) and cases have stopped decreasing in Cordoba and Rosario; raising concerns that this may signal a broader shift in trend in the coming weeks.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 22 November 2020**

**See data, table and figure notes

Eastern Mediterranean Region

The number of new weekly cases (250 746) and deaths (6299) continues to rise in the Eastern Mediterranean Region, 5% and 10% higher respectively than the previous week (Figure 5). Since August, the number of new weekly cases and deaths has risen in the Region, when fewer than 80 000 new cases and 2500 new deaths were reported per week. Iran, Jordan, Morocco, Pakistan, Iraq and Lebanon reported the highest numbers new cases.

The number of new cases in Iraq has declined by 20% over the past week to 16 640 cases (1092 cases per 1 million population). The number of weekly new cases has declined since the week of 19 October when there were 25 629 new cases. The number of new deaths has also declined steadily and Iraq reported an 11% decline from last week to only 302 deaths. WHO concluded a [COVID-19 prevention and awareness campaign](#) that targeted approximately 4 million people, including refugees and internally displaced people in the Kurdistan region.

Jordan is reporting 36 800 new cases this week, a 1% rise from last week and the second -highest number of incident cases in the Region (after the Islamic Republic of Iran). The number of new weekly cases has continued to increase since August, when there were fewer than 50 cases reported. Jordan has the highest number of new cases per 1 million population in the Region with 3 612 new cases per 1 million. Last week nearly half of cases were reported from the capital, Amman, followed by Irbid, Aqaba, and Zarqa. Although most cases have been in the 25-34 age group, around 80% of deaths last week were in those aged 55 and over. Jordan also has the highest number of new deaths per 1 million population in the region with 45.9 deaths per 1 million population. The number of weekly deaths has increased since August, but in the past week declined by 11% to 468 new deaths.

The number of new cases in the occupied Palestinian territory, including east Jerusalem, increased by 78% last week to 8 430 new cases (1652 cases per 1 million population). This represents the highest number of new cases since the pandemic began, and is higher than the previous peak of over 6200 cases reported in the third week of September. Gaza remains a pressing concern as it is ill-equipped to face a major spike in cases due to poor living conditions and a fragile healthcare system.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 22 November 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

In the past week, the number of new cases reported in the European Region declined by 6% to 1.77 million, after a decline of 10% in the previous week (Figure 6); in a sign that the re-introduction of stricter public health and social measures in a number of countries over the last few weeks is beginning to slow down transmission. Despite this reduction in new cases, the Region still accounts for 44% of global new cases and 49% of global new deaths. New deaths in the Region have continued to rise with 32 684 new deaths reported in the past week.

This week, Italy reported the highest number of new cases in the Region and third-highest globally, with 235 979 new cases (3902 cases per 1 million population); however, cases may have peaked given the slight (3%) decline reported. The number of new deaths increased by 26% to 4578 new deaths (75 deaths per 1 million population). The northern Italy provinces of Valle d'Aosta, Bolzano and Piemonte report the highest number of cases. Media reports have highlighted concerns of the large number of COVID-19 patients in intensive care, and the growing number of health worker infections, straining local healthcare capacities.

The number of new cases in the United Kingdom fell by 13% from last week to 149 027 new cases (2195 cases per 1 million population), while the number of new deaths remained similar. This decline in new cases represents the first weekly decline since late August. Since 24 August, the number of COVID-19 tests conducted daily has increased from 179 000 to 330 000 on 13 November (7 -day daily average). The number of patients admitted to hospital has also grown from fewer than 100 per day at the end of August, to 1 600 on 14 November; however, this is considerably lower than hospitalizations in early April, when there were over 3000 patients admitted daily. The United Kingdom currently has the fifth- highest number of new cases in the European Region, and the eighth highest number worldwide, however, per capita case incidence remains lower than many other countries in the Region.

Poland reported 152 357 new cases (4026 cases per 1 million population), a 10% fall from last week. The number of new deaths has risen by 35% to 3243 new deaths (or 85 new deaths per 1 million population). Cumulative cases have been highest in the south of Poland, in the provinces of Silesia and Lesser Poland, and in central Poland, in the provinces of Mazowieckie and Greater Poland.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 22 November 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

The South-East Asia Region has observed a continued decline in the number of weekly new cases since mid-September with over 351 000 cases reported, while the number of weekly new deaths has remained at similar levels over the past four weeks with 4 706 deaths (Figure 7). The regional trend is largely driven by the decline in cases in India, which comprises 80% of the Region's new weekly cases. Countries with the highest number of weekly new cases were India, Indonesia, Bangladesh, Nepal and Myanmar.

In Myanmar, a 74% increase in cases was observed in the past week, with over 11 000 new cases (204 cases per 1 million population) reported. The number of total new deaths was 188, a 36% increase compared to the previous week. This trend is a change from the decrease in cases observed since the week commencing 12 October. The government has extended the existing COVID-19 prevention measures until the end of November, including the temporary suspension of international and domestic flights. Health authorities are concerned about a potential increase in cases following gatherings which occurred during the recent election and are closely monitoring the situation.

In Sri Lanka, 3580 new cases (167 cases per 1 million population) were reported in the past week, a 29% increase compared to the previous week and the highest number of cases reported in a week since the beginning of the pandemic. The number of new deaths reported was 30, continuing the upward trend in the number of deaths observed in the past five weeks. Due to increasing cases, public health and social measures have been introduced. In the Colombo and Gampaha Districts in Western Province, there are movement restrictions in 18 divisions which will be continued in the coming weeks, as well as in eight districts where restrictions will be lifted this week.

In Bangladesh, a gradual increase in the weekly number of cases observed since October continued, with over 14 000 new cases (90 cases per 1 million population) in the past week (a 26% increase compared to the previous week). Although there had been a downward trend in deaths since the beginning of September, a 43% increase was reported in the past week with 177 new deaths compared to the previous week. National authorities have closed schools and educational institutions since 17 March. Most school children in Bangladesh do not have access to the internet, so the government is broadcasting lessons on television, and universities are providing classes online. Despite relatively stable testing, the proportion of positive tests has slightly increased over the past month, suggesting an increase in cases and spread of the disease.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 22 November 2020**

Western Pacific Region

Over the past week, the Western Pacific Region recorded over 36 000 cases and 439 deaths. The Region observed a continued increase of cases, with a 9% increase compared to the previous week, while deaths remained stable compared to the previous week. Varying patterns of trends were observed in the Region, where countries including Japan, Republic of Korea, Mongolia and Australia reported an increase in cases compared to the previous week, whereas countries including the Philippines, French Polynesia, Guam, China and Singapore observed a decreasing trend. Japan, Philippines, Malaysia, Republic of Korea and French Polynesia reported the largest number of new weekly reported cases.

Japan reported the largest number of daily cases since the beginning of the outbreak with over 2000 cases reported per day for five consecutive days, and 13 502 new cases (107 cases per 1 million population) reported in the past week, a 41% increase from the previous week. There has been a resurgence in cases over the past three weeks following a relatively stable number of cases in September and October. The largest number of daily cases to date were observed in prefectures including Tokyo and surrounding prefectures, Osaka and Hokkaido. The COVID-19 alert level in Tokyo Prefecture has been raised to the red level, which is the highest of the four categories. The number of newly reported deaths in the past week was 91, which was an increase by 28%.

Mongolia observed a sharp upward trend with 166 new weekly cases (51 cases per 1 million population), following a period of low levels ranging from 0 to 17 weekly cases from July to October. The number reported this week was more than twice the number reported in the previous week. On 11 November, Mongolia reported its first case of COVID-19 transmission in the community. Although there have been many imported cases reported, this case in the capital city of Ulaanbaatar was the first instance of transmission within the country. Two separate clusters were detected soon after in Selenge province which borders the Russian Federation. One of the clusters in Selenge was traced back to an event in early November, which has led to local clusters with linked cases in the provinces of Darkhan-Uul, Govisumber, Orkhon and Dornogovi. Mongolia declared a state of emergency on 12 November. No deaths have been reported in Mongolia since the beginning of the pandemic.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 22 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- WHO and other UN agencies issued a [Joint Statement on Data Protection and Privacy in the COVID-19 Response](#), calling for the use of data and technology in the COVID-19 response in a way that respects the right to privacy under international law, data protection and privacy principles, as well as the right to health, and economic and social development.
- In his [opening remarks at the Member States briefing on COVID-19](#), WHO Director-General Dr Tedros thanked Member States for their continued solidarity in the response to COVID-19 and for the successful 73rd session of the World Health Assembly which was conducted under challenging circumstances.
- In his [opening remarks at the 20 November 2020 media briefing on COVID-19](#), Dr Tedros highlighted the positive news from vaccine trials in the past week and reminded that “we must continue to use the tools we have to interrupt the chains of transmission and save lives now”. He also emphasized that the pandemic is a “stark reminder of the intimate relationship between humans, animals and the planet we share. We cannot protect and promote human health without paying attention to the health of animals and the health of our environment”.
- Diagnostic testing is an essential part of the comprehensive strategy to control COVID-19. The [COVID-19 Reference Laboratory Network](#), established in six WHO regions in early 2020, has supported strengthening diagnostic capacity across the world. This feature story offers [a look inside laboratories responding to COVID-19](#).
- WHO launched the Global Strategy to Accelerate the Elimination of Cervical Cancer, in which 194 countries [committed to eliminat cervical cancer](#). Although COVID-19 has posed challenges to providing health services related to cancer, the strategy aims to reduce new cervical cancer cases by more than 40%; and reduce deaths by 5 million by 2050 through vaccination, screening and treatment.

WHO has published the following documents:

- [Guidance on developing a national deployment and vaccination Planning for COVID-19 vaccines](#), which is intended to guide national governments in developing and updating their national deployment and vaccination plan for COVID-19 vaccines.
- [Maintaining surveillance of influenza and monitoring SARS-CoV-2 adapting Global Influenza surveillance and Response System \(GISRS\) and sentinel systems during the COVID-19 pandemic](#), which is interim guidance for countries to monitor the circulation of influenza and SARS-CoV-2 viruses. It includes updated considerations for addressing disruptions in influenza sentinel surveillance, extending influenza surveillance to include COVID-19 wherever possible, as well as provides updated algorithms for testing influenza and SARS-CoV-2.
- [Priority medical devices list for the COVID-19 response and associated technical specifications](#), which describes the medical devices required for the clinical management of COVID-19, selected and prioritized according to the latest evidence and guidelines.
- [Diagnostics, therapeutics, vaccine readiness, and other health products for COVID-19](#), which was developed to assess present and surge capacities for the treatment of COVID-19 in health facilities.
- [Continuity of essential health services: Facility assessment tool](#), which can be used by countries to rapidly assess the capacity of health facilities to maintain essential health services during the pandemic.
- [Therapeutics and COVID-19: living guideline](#), which contains new information for clinicians including a new conditional recommendation against the use of remdesivir in hospitalized patients with COVID-19, regardless of disease severity.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Global totals include 741 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps

represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 15 November 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

The number of new cases being reported globally continues to rise (Figure 1), with almost 4 million new cases in the past week (9–15 November) alone. The number of new deaths globally has also grown by 11%, with almost 60 000 new deaths reported, of which 81% were in Europe and the Americas (Table 1).

Although the European Region continues to report the highest number of new cases globally (46%), it has seen a 10% fall in the past week following the strengthening of public health and social measures across the region. However, the number of new deaths in Europe has increased substantially with over 29 000 new deaths reported in the past week. The Region of the Americas reported a sharp upward trend, with a 41% increase in new cases in the past week. The Eastern Mediterranean, African and Western Pacific Regions also reported increases in the number of new cases. The South-East Asia Region, on the other hand, reported a decline in the number of new cases and new deaths.

As of 15 November, over 53.7 million cases and 1.3 million deaths have been reported globally.

Figure 1: COVID-19 cases reported weekly by WHO Region, and global deaths, as of 15 November 2020**

**See [data table](#) and [figure notes](#).

Countries reporting the highest number of cases in the past week included: the United States of America (reporting over 1 million new cases, a 47% increase compared to the previous week), India (306 000 cases, 5% decrease), Italy (242 000 cases, 9% increase), France (203 000 cases, 47% decrease), and Brazil (179 000 cases, 57% increase).

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

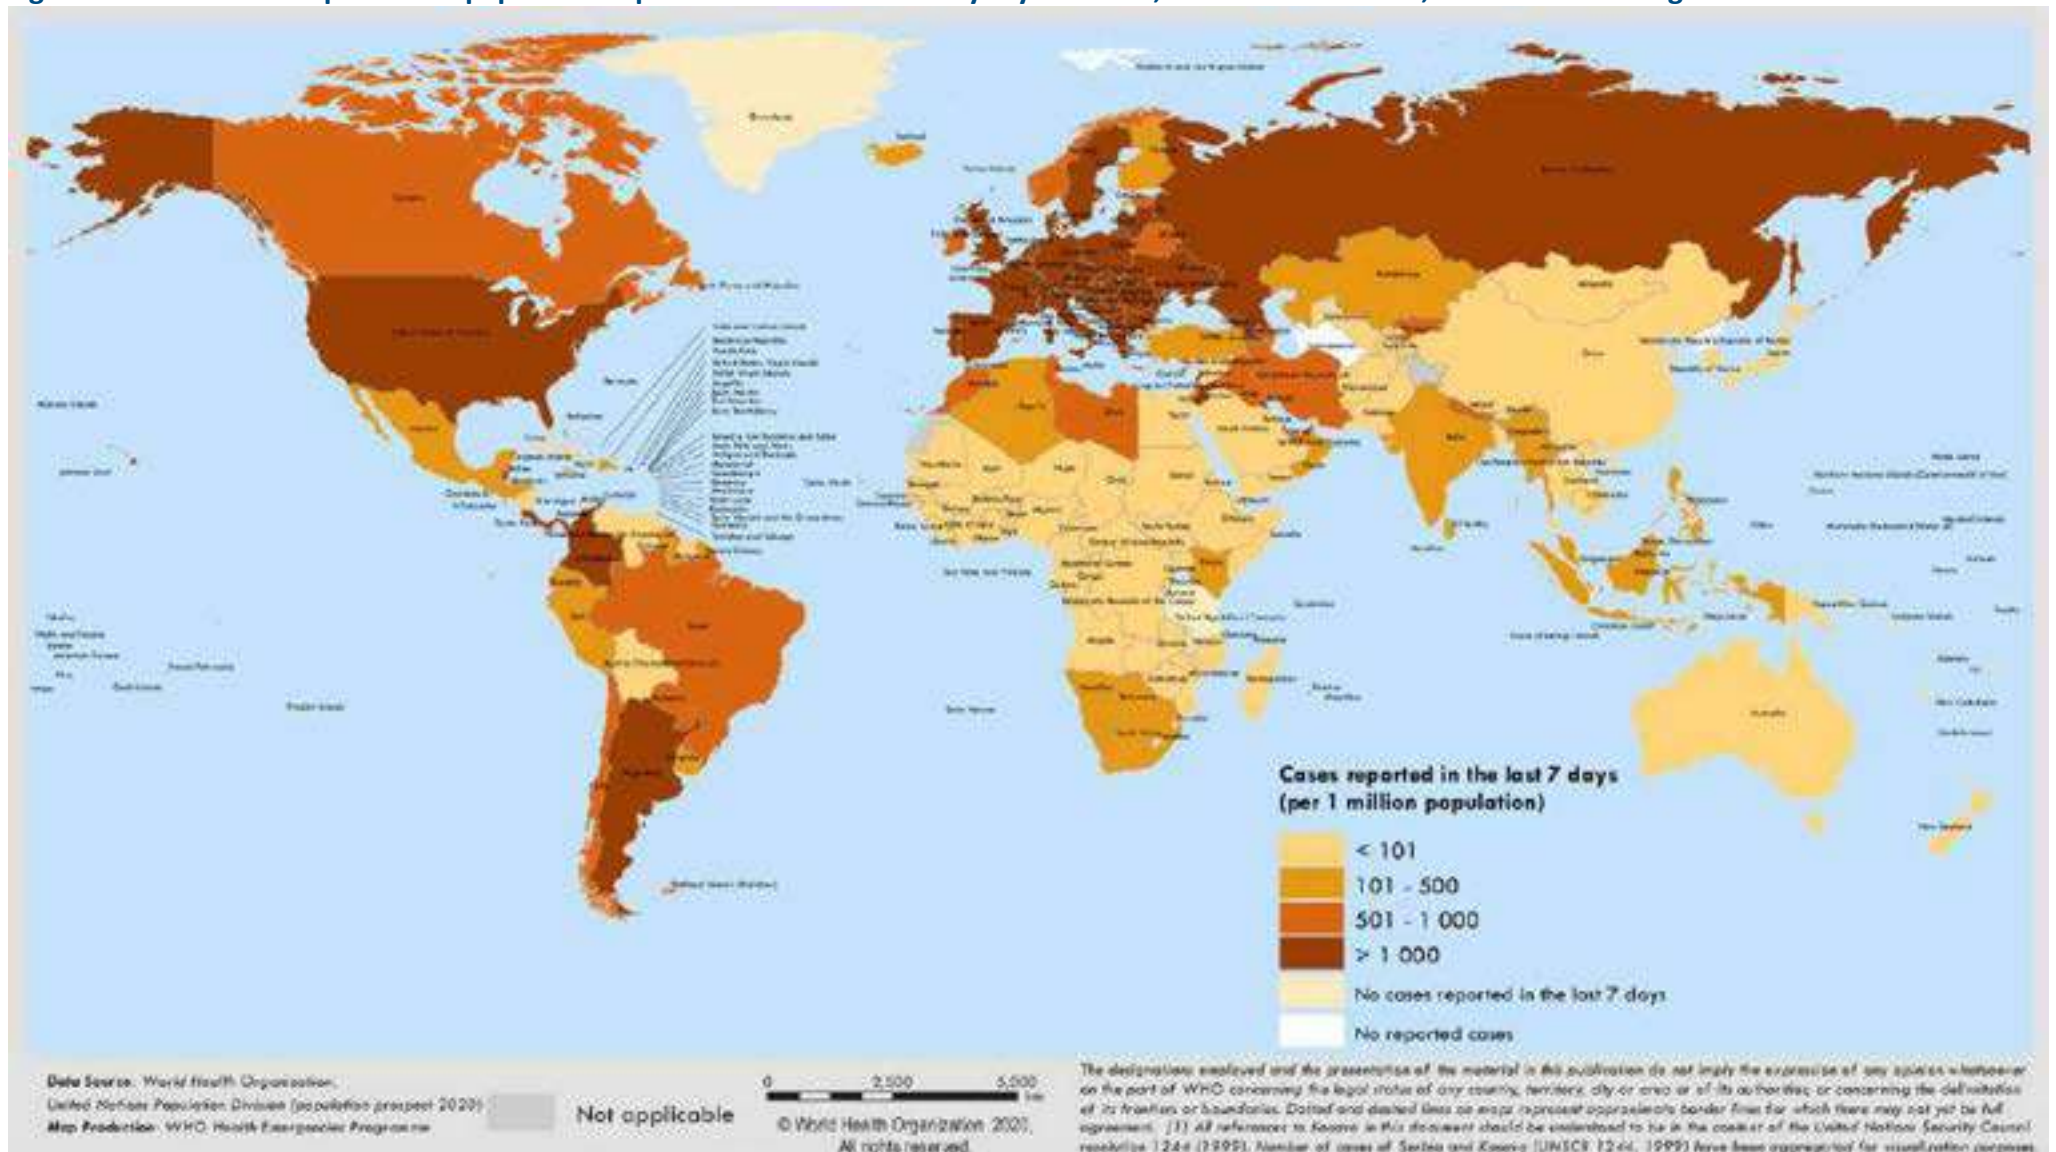

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 15 November 2020**

Situation by WHO Region

African Region

In the African Region, the gradual increase in the number of new weekly cases since last September continued, with 40 990 new cases reported, a 22% increase compared to the previous week (Figure 3). Death rates across the region remained similar to the previous week. South Africa, Kenya, Algeria and Ethiopia reported the largest number of new weekly cases in the region.

Algeria reported a sharp (131%) increase in the past week, with 5806 new cases detected (132 cases per 1 million population) and 114 new deaths reported. Local authorities also reported a substantial rise in hospitalisations in October, most notably in the north-eastern and north-central provinces. On 8 November, the Algerian Government implemented 12 additional new public health and social measures to mitigate this surge, including the reinstatement of a night-time curfew, closure of vehicle markets for 15 days, banning public and family gatherings, and postponing the start of university classes and vocational training until 15 December.

In Angola, the incidence of new cases continued to decline, with 1039 new cases (32 cases per 1 million population) reported in the past week, a 32% decrease compared to the previous week. Nineteen new deaths were reported in the past week. As of 14 November, 66% of confirmed cases reported in Angola were male and 86% were individuals aged 20 to 69 years. The capital city of Luanda has been considered the epicentre of the outbreak in the country, with 78% of cumulative cases and 84% of deaths to date.

On 11 November, the South African government further eased public health and social measures as the national incidence of new cases remains relative steady, with about 13 000 new cases (224 cases per 1 million population) reported in the past week, while rates of COVID-19 associated hospitalizations and deaths continue to fall. However, the government warned of potential resurgence, highlighting recent spikes in cases observed in Nelson Mandela Bay Metropolitan area, Eastern Cape Province, potentially triggered by outbreaks in educational institutions and among people attending large gatherings.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 15 November 2020**

**See data, table and figure notes

Region of the Americas

Cases and deaths in the Region of the Americas continue to rise (Figure 4), with cases increasing over 40% and deaths over 10% in the past 7 days.

The United States of America reported the largest number of cases in the Region, with over 1 million cases (3036 cases per 1 million population) in the past week, amounting to nearly 11 million cumulative cases since the start of the pandemic.

In Canada, upward trends in both cases and deaths have continued, with over 30 000 new cases (835 new cases per 1 million population) and just under 400 new deaths (10 new deaths per 1 million population) in the past week. Increased activity has also been reported among vulnerable populations and settings (such as elderly adults and Indigenous communities, and in a range of settings including long-term care and assisted living facilities, schools, congregate living settings, industrial work settings and social gatherings). Overall, nearly 300 000 confirmed cases and 11 000 deaths have been reported from Canada since the start of the pandemic.

Mexico reported 42 465 new cases this past week (328 new cases per 1 million population), a 16% increase compared to the previous week. There have been reports of increased hospitalizations in the northern state of, this region has been placed under the highest Coronavirus alert level, joining the neighbouring region of Chihuahua, which borders the United States of America. Death rates in the country increased by 9% in the past week, with 3301 new deaths reported.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 15 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

The incidence of new cases continued to increase in the Eastern Mediterranean Region (Figure 5), with over 238 000 new cases this past week, an 11% increase on the previous week, while the number of reported deaths was similar. Countries which reported the greatest number of new cases included Iran, Jordan and Morocco.

In Pakistan, a resurgence is being observed with over 12 000 (58 cases per 1 million population) new cases reported in the past week – a 45% increase on the previous week. The weekly number of deaths also rose by 21%, with 166 reported. Country officials have strengthened public health and social measures in light of these increases. Considering the large population of Pakistan (over 220 million people), concerted efforts to reduce transmission have thus far been relatively successful.

In Afghanistan, a 65% increase was observed this past week, with 1002 new cases (26 cases per 1 million population) reported. As of 12 November, test positivity rates in the country were estimated at over 33%, highlighting the limitations in the testing capacity, testing criteria and willingness of people to come forward for testing, with stigma considered as a major factor in the decision not to get tested. Men accounted for more than 69% of the total confirmed cases, and most recorded deaths were among men aged 50-79 years, which may in part be due to men being over-represented in testing.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 15 November 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

Over the past week, the European Region recorded 46% of all cases and 49% of all deaths reported globally, with nearly 2 million new cases and almost 30 000 new deaths. However, in the past week, for the first time in over three months, the region observed a decline of 10% in weekly cases (Figure 6). At the same time, deaths continued to increase, with an 18% increase the past week in comparison to the previous week.

Varying patterns were seen in Europe with decreases in cases being observed in 24 countries in the past 7 days, ranging from a 2% to over 40% decrease in new cases in these 24 countries compared to the previous week. Whereas in other countries, weekly increases in new cases ranging from 1% to over 40% were reported. The countries reporting the highest number of cases in the past week were Italy, France, the United Kingdom, Poland, the Russian Federation, Germany, Spain, Ukraine, Romania, and Austria. Among these ten countries, Austria reported the sharpest increase, with new cases this week 30% higher compared to the previous week. The countries with the highest weekly mortality rates, exceeding 60 deaths per 1 million population, were Czechia, Bosnia and Herzegovina, Belgium, North Macedonia, Armenia, Hungary, Bulgaria, Poland, France, Croatia and Montenegro. The United Kingdom was the first country in the region to record over 50 000 cumulative deaths.

The Russian Federation recorded its highest case and death counts, with over 150 000 cases (1038 cases per 1 million population) and over 2600 deaths reported in the past week. Public health interventions were strengthened across many regions. Moscow expanded public health and social measures, including switching universities to online learning and limiting the time during which restaurants and bars can serve customers.

Lithuania was also among the countries which reached a peak in cases and deaths over the past week, with more than 10 500 new cases (3919 cases per 1 million population). Similar to other countries in the region, Lithuania expanded public health and social measures in the first weeks of November. Additionally, Lithuania is adapting its hospital network to meet growing demands through expanding bed capacity and will set up a temporary hospital in a large exhibition center in Vilnius.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 15 November 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

The South-East Asia Region observed six weeks of continued decline in cases and deaths from the second half of September until the end of October (Figure 7). New weekly cases fell from over 690 000 to around 380 000, and new weekly deaths decreased from over 9300 in the week commencing on 14 September to under 4600 in the past week. Since the start of November, weekly cases have stabilized under 400 000 for the past three weeks, with 373 786 cases reported in the past week. Weekly deaths have also remained relatively stable, with 4534 deaths reported in the past week. Countries with highest number of weekly new cases per million population in the past week included Nepal, Maldives and India.

The regional trend continues to be strongly influenced by India, which consistently reports the highest numbers of cases and deaths in the Region. After a period of sharp decline, cases and deaths in India have stabilized since the end of October. In the past week, further decreases of 5% in cases and 12% in deaths were observed, with 306 825 cases (222 cases per 1 million population) and 3 514 deaths reported. At the end of the week, the states of Maharashtra, Kerala and Delhi reported the highest numbers of new cases, with over 80 000 in Maharashtra and almost 40 000 in Delhi.

Indonesia reported the second highest number of cases in the Region in the past week. Until 8 November, Indonesia had observed a weekly decline in cases for six consecutive weeks, with weekly cases falling from over 30 000 in the week commencing on 21 September to under 23 800 in the week commencing 2 November. However, in the past week, the country registered over 29 000 new cases (107 cases per 1 million population), a 23% increase from last week. Towards the end of the week, Indonesia registered over 5200 daily cases for two consecutive days. On both days, Jakarta and Jawa Tengah Provinces reported the highest case numbers in the country, surpassing 1000 each day.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 15 November 2020**

**See [data, table and figure notes](#)

Western Pacific Region

The number of cases continues to gradually rise in the Western Pacific Region (Figure 8), which reported nearly 33 000 new cases and over 400 deaths in the past week. New cases increased by 5% and new deaths increased by 15% compared to the previous week. This reporting period is the second consecutive week that the Western Pacific Region reported more than 30 000 new cases per week since mid-September. The Philippines, Japan, Malaysia and French Polynesia reported the highest number of cases in the region.

Guam reported 820 new cases (4859 cases per 1 million population) in the past week, more than double the number of cases reported the previous week, and the highest weekly count since the beginning of the pandemic. Four new deaths were reported, bringing the total to 93 cumulative deaths. In a correctional facility, 60 inmates and one officer tested positive for COVID-19 in the past week and are currently in isolation.

Malaysia reported 6852 new cases in the past week (212 case per 1 million population). Although the number of cases decreased by 12% compared to the previous week, there has been a general upward trend since the beginning of September. Twenty-four new deaths were reported in the past week, bringing the cumulative total to 306 deaths. Selangor State, which is the most populous state in the country with approximately 19% of the population, reported 28% of cases, followed by Kuala Lumpur which reported 16% of cases. Many cases reported in the past week were linked to previously reported clusters in Sabah State, which reported the highest number of local transmissions, including cases identified by close-contact screenings and existing clusters.

In Vanuatu, the first confirmed case was reported on 10 November. The case was a young adult who returned on 4 November from the United States of America. The case, who was asymptomatic, tested positive during routine testing on the fifth day of quarantine. In accordance with the preparedness and response plan, the case will remain in isolation until health clearance is given. Health authorities initiated contact tracing with close contacts, and intensified risk communication and community engagement activities.

Key weekly updates

- In his opening remarks at the resumed [73rd session of the World Health Assembly \(WHA 73\)](#), WHO Director-General Dr Tedros highlighted how the “world has come together as never before to ensure that the life-saving tools being developed to combat COVID-19 are developed, produced and allocated fairly as global public goods, and not private commodities that become one more reason some people are left behind”.
- In his closing remarks at WHA 73, he welcomed the preliminary results of vaccine clinical trials released in the week: [Never in history has vaccine research progressed so quickly](#)”. On 16 November, at an Executive Board meeting, he also emphasized that a vaccine will complement the other tools we have, not replace them: “[A vaccine on its own will not end the pandemic](#)”.
- A [report](#) by the Independent Oversight and Advisory Committee for the WHO Health Emergencies Programme concluded that over the last four years, the WHE Programme has demonstrated its capacity to manage multiple emergencies and has helped affirm WHO’s position as a global health leader.”
- Donor commitments to the [Access to COVID-19 Tools \(ACT\) Accelerator](#) have [reached US 5.1 billion following new contributions at the Paris Peace Forum](#). This concerted global effort among heads of state, global health leaders, scientists and the private sector is helping secure a way to end the acute phase of the pandemic by deploying the tests, treatments and vaccines the world needs to fight the pandemic. However, an additional US 4.2 billion is needed urgently this year, with a further US 23.9 billion required in 2021, if tools are to be deployed across the world as they become available.
- At the Paris Peace Forum, the Director-General outlined [three fundamental shifts that WHO believes all countries must make](#): (1) Invest in basic public health systems, which are the bedrock for preventing, preparing for, detecting and responding to outbreaks; (2) Take a One Health approach. The [COVID-19 pandemic is a stark reminder of the close links between the health of humans, animals and the planet we share](#); (3) Go beyond the health sector: the pandemic has affected every sector.
- WHO has announced the establishment of the [Council on the Economics of Health for All](#), composed of leading economists and health experts, to put “Health for All” at the center of how we think about value creation and economic growth. “The COVID-19 pandemic has demonstrated the consequences of chronic under-investment in public health. But we don’t just need more investment; we must also rethink how we value health” said the WHO Director-General.
- 2021 has been designated as the [International Year of Health and Care Workers](#), in recognition of the dedication and sacrifice of the millions of health and care workers at the forefront of the pandemic.
- The special edition of the timeless hit *Here I Am*, is now available for download worldwide from digital music stores such as iTunes, Spotify and Amazon Music. The song is being released as an inspiring [call for global solidarity](#) to respond to the COVID-19 pandemic and to generate proceeds in benefit of the [WHO Foundation](#) to address the most pressing global health challenges of our time.
- WHO has published the following documents:
 - [Immunization as an essential health service: guiding principles for immunization activities during the COVID-19 pandemic and other times of severe disruption](#), which provides support to countries in their decision-making regarding provision or resumption of immunization services during events such as COVID-19, natural disasters or humanitarian emergencies.
 - The [Emergency Global Supply Chain System \(COVID-19\) catalogue](#) which lists all medical devices, including personal protective equipment, medical equipment, medical consumables, single use devices, and laboratory and test-related devices that may be requested through the [COVID-19 Supply Portal](#).
 - [Technical specifications of personal protective equipment for COVID-19](#), which provides guidance on the quality, performance characteristics and related standards of personal protective equipment to be used in the context of COVID-19.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Global totals include 741 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps

represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 8 November 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

In the past week, the global number of cases of COVID-19 has increased by 8% compared to the previous week, totalling more than 3.6 million new cases, while new deaths have increased by 21% to over 54 000. This brings the cumulative numbers to over 49.7 million reported cases and over 1.2 million deaths globally since the start of the pandemic. The European Region continues to account for the greatest proportion of new cases and deaths in the past 7 days, the Region reported over half (54%) of all new cases and nearly half (47%) of new deaths. Although it still accounts for only 2% of the global total number of cases and deaths, this week the Western Pacific Region showed the largest relative proportional increase in new cases (19%) compared to the previous week followed by the Eastern Mediterranean Region (18%) and the European region (11%). The three regions reporting the highest proportional increases in newly reported deaths in the past 7 days compared to the previous week are Europe (44%), Africa (30%) and the Eastern Mediterranean (23%). The Western Pacific Region was the only region to report a decrease in deaths (5%) this week compared to the previous week.

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, as of 8 November 2020**

**See [data table and figure notes](#).

The five countries reporting the highest number of cases in the past week were The United States of America, France, India, Italy and the United Kingdom.

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western Pacific Region](#).

Situation by WHO Region

African Region

The number of new cases continues to increase very gradually in the African Region, which reported nearly 34 000 new cases and 831 new deaths in the past week. The number of new deaths reported in the last 7 days was 30% higher than it was in the previous week, driven largely by increases seen in South Africa, Kenya, and Uganda.

South Africa continues to report the highest number of new cases and deaths in the Region, accounting for nearly a third of new cases and over half of new deaths. The number of new cases reported by South Africa peaked mid-July, the height of winter, when there were more than 86 000 cases reported weekly. By September, South Africa was reporting fewer than 15 000 cases per week, and in the past week there were nearly 10 500 cases reported (176 new cases per million population). The number of deaths has also fallen from over 1 500 deaths per week at the end of July and beginning of August, to 513 deaths reported in the past week (although this is 55% higher than it was in the previous week). As of 31 October, five provinces reported over 80% of cases: Gauteng, KwaZulu-Natal, Western Cape, Eastern Cape, and Free State. The median age of COVID-19 cases in South Africa is 39 years, and 58% of cases are female. The reason for this higher prevalence among females could be due to females being more represented in certain occupations in education and health sectors where they may be at greater risk of infection, as well as differences in health seeking behavior.

Kenya is reporting the second- highest number of weekly new cases in the African Region. The number of new cases rose at the end of July, with 4 700 cases in the week beginning 27 July. The number of cases then has risen considerably in October, rising from 1 000 new cases in the first week of October (28 September-4 October) to 6 577 cases (122 new cases per million) in the past week.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 8 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Region of the Americas reported over 1 million new cases in the last week, a 3% increase as compared to the previous past week. The Region accounted for 32% of all deaths reported globally in the past week (n 17 289). The United States of America, Brazil, Argentina, Colombia and Mexico reported the highest number of new cases in the last 7 days.

Brazil has reported over 5.6 million cumulative cases and over 162 000 cumulative deaths since the beginning of the pandemic. The number of cases reported per week peaked in the week of July 27 at 319 119 cases and has gradually decreased since then, although the absolute number remains high. In the last week Brazil reported 114 523 new cases and 2 538 deaths which represent 30% and 16% decreases respectively compared to the previous week. The Southeast region of the country reported the highest cumulative numbers of cases and deaths with over 1.9 million cases and 73 261 deaths, followed by the Northeast region with over 1.4 million cases and 42 480 deaths, as of 4 November 2020. In Rio de Janeiro, businesses, beaches, private schools and nurseries have reopened with restrictions.

Martinique reported the highest surge in cases since the beginning of the pandemic in the week beginning 26 October, with 1 024 cases reported. In the past week, 397 new cases (1 058 new cases per 1 million population) were reported, which is a 61% decrease compared to the previous week. This decrease was the first downward trend in weekly cases since the week beginning 21 September. On 30 October, movement and travel restrictions were instated to limit contact and travel in Martinique. Schools, excluding higher education institutions, remain open with reinforced public health measures.

In Belize, the number of new cases reported surpassed 500 for the first time since the beginning of the outbreak, with 554 new cases and nine new deaths reported in the past week bringing the total deaths in the country to 67. As of 8 November, approximately 45% of confirmed cases were female, and the highest number of cases were reported from Orange Walk district followed by Belize district.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 8 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

In the Eastern Mediterranean Region, the weekly number of new cases increased by 18% compared to the previous week, bringing the cumulative number of cases to over 3.3 million. In the past week, the number of new deaths in the region increased by 23%, bringing the cumulative number of deaths to over 84 000. The Islamic Republic of Iran, Morocco, Jordan, Iraq and Lebanon reported the highest number of new cases in the last seven days.

Iraq reported 23 389 new cases in the past week (581 new cases per 1 million population). The weekly number of new cases has remained over 23 000 since the week beginning 10 August. The number of deaths per week peaked in the week of 29 June and has gradually decreased to 373 per week (9.3 deaths per 1 million population) in the current reporting period.

Lebanon has recorded 11 869 new cases (1 739 new cases per 1 million population) and 76 new deaths (11.1 new deaths per 1 million population) in the past week. There has been an upward trend of cases and deaths in the past eight weeks in Lebanon.

In Tunisia, 8 428 new cases were reported in the past week, which was just over a 10% decrease compared to the previous week. There were 500 new deaths reported in the past week, which was an 8% increase compared to the previous week. On 29 October, Tunisian authorities stated that classes in elementary and middle schools will be suspended and premises disinfected.

**See [data](#), [table](#) and [figure notes](#)

European Region

The number of new cases and deaths reported in the European Region continues to increase exponentially with 11% and 44% more cases and deaths respectively in the past week compared to the previous week, a record of weekly number of cases since the beginning of the epidemic. Moreover, test positivity rates have been steadily increasing since August and have shown a marked escalation in recent weeks.

This week, the region recorded 54% of all new cases and 47% of all new deaths reported globally bringing cumulative counts in the region to over 13 million cases and 311 000 deaths. Deaths have increased markedly in the past 7 days with France, Spain and Italy reporting the highest counts of new deaths while Czechia, Belgium and Slovenia reported the highest mortality rates per capita. Most of the Member States in the European Region self-characterise their current transmission pattern as either community transmission (55%, n 34) or clusters of cases (32%, n 20).

Over the past three weeks, Denmark has registered an increase in weekly incidence of COVID-19 cases reaching almost 1 400 new cases per 1 million population (14% increase on the previous week). Since June 2020, 214 human cases of COVID-19 have been identified in Denmark with [SARS-CoV-2 variants associated with farmed minks](#), including 12 cases with a unique variant, reported on 5 November. In the past few days, the Danish Prime Minister announced a planned cull of all mink in the country and imposed stricter public health and social measures in the area where the variants associated with farmed mink have been detected in humans.

This week, Spain became the country with the sixth highest number of COVID-19 cases globally, recording over 2 000 new cases per 1 million population and bringing cumulative counts in the country to an excess of 1.3 million cases and almost 40 000 deaths. In the last weeks, the number of COVID-19 patients admitted to hospital has increased steadily and as of 6 November, 6 of the 17 Autonomous Communities in Spain have reached over 40% Intensive Care Unit (ICU) occupancy. Over the last week, a majority of outbreaks affecting 10 people or more in the country continue to be located in care homes for the elderly.

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

The South-East Asia Region had observed a continued declining trend in new cases and deaths over the past six weeks. However, in the past 7 days, almost 400 000 new cases (a weekly increase of 2%) and over 5 000 deaths (a weekly increase of 10%) were reported in the region. The countries reporting the highest numbers of new cases in the South-East Asia region continue to be India, Indonesia and Nepal, while the highest mortality rates were recorded in Nepal and Myanmar.

The only country in the region this week to report a substantial increase in new deaths has been Nepal. In the past week, Nepal reported its highest weekly increase in the number of new deaths with 5 deaths per 1 million population (58% increase compared to the previous week). Moreover, in the past 7 days, Nepal had the highest incidence of new cases per 1 million population (717 new cases per 1 million population) in the region. On 5 November, Nepal reported over 400 cases in ICUs across the country. In the past week and for the first time in seven months, the country reopened to those intending to climb or trek mountain trails.

While India is still reporting the highest number of new cases and deaths in the region, trends in these numbers for the country have stabilized in the past week. Even though the country has reached a total of over 9.5 million cases and almost 127 000 deaths cumulatively, in the past week, India recorded 230 new cases and 3 deaths per 1 million population. The most affected regions in the country are Maharashtra, Karnataka and Andra Pradesh while the regions with the highest number of active cases as of 8 November are Maharashtra, Kerala and Delhi.

A stabilisation in the incidence of cases and deaths has also been observed in Bangladesh in the past few weeks recording less than 70 new cases and less than 1 death per 1 million population in the past week (11 000 cases and 126 new deaths). In Cox's Bazar District, which hosts one of the world's largest refugee settlements, the incidence trends have remained relatively low since early July with a cumulative total of 5 255 COVID-19 cases reported as of 4 November 2020.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 8 November 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

The number of new cases reported in the last week in the Western Pacific (31 370) rose by the highest percentage globally, with a 19% increase compared to the previous week. Despite this increase, the number of new cases reported represents 1% of new cases reported globally last week. The number of new deaths was 5% lower than the previous week. The Philippines, Malaysia, Japan and French Polynesia continue to report the highest numbers of new cases in the Region: the Philippines reported 13 232 new cases (121 new cases per million); Malaysia reported 7 809 new cases (241 new cases per million); and Japan reported 5 940 new cases (47 new cases per million).

The number of new cases in Japan peaked in the week of 3 August with over 10 000 cases. The number of new cases then dropped until the week of 21 September when just over 3 000 cases were reported. However, it has since been rising, and there were 5 940 new cases reported in the past week (a 29% increase from the previous week). Despite this increase last week, Japan reported 47 new cases per 1 million population, a relatively low number. Similarly, the number of new deaths in Japan remains very low and decreased by 16% compared with the previous week to 46 deaths, with only 0.4 deaths per million population.

COVID-19 cases started rising in French Polynesia from only a few cases at the beginning of August to 2 733 new cases reported last week. The number of new cases rose by 95% from the previous week.

Cases in the Republic of Korea have gradually increased in October, from around 500 new cases per week at the start of the month to 799 new cases reported in the week of 26 October. Last week the Republic of Korea reported 792 new cases which is a 1% decrease in comparison to the previous week.

Key weekly updates

- As health leaders gather virtually for the resumed 73rd session of the World Health Assembly, [WHO has three messages to share](#):
 1. We can beat COVID-19 with science, solutions and solidarity: many countries and cities have successfully prevented or controlled transmission with a comprehensive, evidence-based approach
 2. We must not backslide on our critical health goals: health is the foundation of social, economic and political stability
 3. We must prepare for the next pandemic now: countries with robust health emergency preparedness infrastructure have been able to act quickly to contain and control the spread of the SARS-CoV-2 virus
- WHO has published the following documents:
 - An [update to the guidance on critical preparedness, readiness and response actions](#), including further subclassifications of transmission scenarios within the community transmission category; and updated guidance on contact tracing, laboratory testing, infection prevention and control, public health and social measures and health services.
 - An [update to the guidance on considerations for implementing and adjusting public health and social measures \(PHSM\)](#) in the context of COVID-19. PHSM are being implemented and adjusted across the globe to limit transmission and reduce mortality and morbidity from COVID-19.
 - An [update to guidance on health facility assessments](#), to inform the prioritization of actions and decision-making at health facility, subnational and national levels.
 - The [Terms of References for a WHO-convened Global Study of the Origins of SARS-CoV-2](#). This outlines two phases of studies: Short term studies (Phase 1) will be conducted to better understand how the virus might have started circulating in Wuhan, China. Building on the findings of these short-term studies, and the scientific literature, longer term studies will be developed (Phase 2).
 - A [policy brief on readiness for influenza during the COVID-19 pandemic](#), which provides a concise summary of information and considerations for key issues policymakers may face. The document also includes links to relevant guidance and resources for monitoring the situation, preventing seasonal influenza, reducing severe complications and mortality, protecting specific populations, and communicating to and engaging with the public.
- UNICEF and the World Health Organization issued an [urgent call to action to avert major measles and polio epidemics](#) as COVID-19 continues to disrupt immunization services worldwide, leaving millions of vulnerable children at heightened risk of preventable childhood diseases. WHO estimates that \$655 million US dollars is needed to address dangerous immunization gaps in children in [non-Gavi eligible countries](#).
- WHO and the International Coalition of Medicines Regulatory Authorities have released a [joint statement on the need for improved global regulatory alignment on COVID-19 medicines and vaccines](#). Therapeutics and vaccines against COVID-19 can only be rapidly approved if applications are supported by robust and sound scientific evidence that allows medicine regulators to conclude on a positive benefit-risk balance for these products.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Global totals include 741 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 1 November 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

In the past week, over 3.3 million new cases have been reported globally (Figure 1). As of 1 November, nearly 46 million cases and 1.2 million deaths have been reported globally. The further acceleration in the incidence of new cases was most notable in European Region, which reported half of global new cases (over 1.7 million cases - a 22% increase from the previous week. Moreover, the region also reported a substantial rise in the number of new deaths (a 46% increase compared with the previous week), with Europe and the Americas now each reporting over 17 000 new deaths in the last 7 days.) The Americas and the Eastern-Mediterranean Regions have also seen relatively smaller rises in the number of reported cases. The South-East Asia Region has continued to report a decline in new cases and deaths, while case incidence continues to fluctuate around similar rates compared to recent weeks in the African and Western Pacific Regions (Table 1).

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, as of 1 November 2020**

**See [data table and figure notes](#).

Despite regional variations, the countries reporting the highest number of cases in the past week remain the same as in the previous four weeks: The United States of America, India and France. Since the start of the pandemic, nine countries have reported more than 1 million confirmed cases: the United States, India, Brazil,

Russian Federation, France, Spain, Argentina, Colombia, and the United Kingdom. Five have reported over 40 000 cumulative deaths: the United States, Brazil, India, Mexico, and the United Kingdom.

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

Special Focus: An age and gender analysis of COVID-19

Based on WHO's surveillance system, using both case report form data and weekly aggregated data shared by Member States, an analysis has been conducted and is presented here, covering 124 countries from five out of six WHO Regions which have provided sufficient data. The data covers the period 31 December 2019 to 18 October 2020, and includes data on 18 156 074 patients.

Age distribution over time

Since the start of the pandemic, an increase in the proportion of confirmed cases in younger population groups has been observed over time (Figure 3). Most notably, the proportion of cases among adolescents and young adults aged 15-24 years increased from 4% at the beginning of the epidemic (week 9-10) to 14% during week 42, and those aged 25-64 increased from 50% to 65% over the same period. Slight increases were also observed in the proportion of cases among children aged 0-4 years (from 0.5% to 2%), and 5-14 years (from 1% to 5%). Concurrently, we observed a decrease and then stabilization of the proportion of cases aged 65 years and older, from 40% in the early stages of the epidemic, down to 15% in recent weeks.

Figure 3: Distribution of confirmed COVID-19 cases by age by epidemiological week reported, combined data from WHO Case Report Form and Weekly Aggregate Surveillance Systems as of 18 October 2020 (n 18 156 074).

Changes in age distribution trends are likely linked to several factors, including increased surveillance and access to testing. Early in the pandemic, surveillance and limited testing capacity was often focused on patients with severe disease, who were more likely to be elderly hospitalized patients. Surveillance and testing capacities were expanded and became more accessible to cases with mild or no symptoms. The decrease in proportion of elder cases could also be linked to the implementation of infection prevention and control measures in long term care facilities, and an increase in transmission among younger age groups.

The evolution of reported deaths by age (Figure 4) shows a slow increase in the proportion of reported deaths aged 25-64 years, ranging from roughly 10% in the early stages, peaking at 30% in the summer, and now around 25%. Reported deaths in those aged 65 years and older decreased from close to 90% in the early stages to 75% in the most recent weeks. These data support previous observations that older people, who often have

co-morbidities, remain the most vulnerable to COVID-19 morbidity and mortality. The proportion of reported deaths in the youngest age groups, 0-4 and 5-14 years, remain under 0.2%.

Critically, while most people with COVID-19 recover after 2 to 6 weeks, there is increasing documentation of the [long term effects of COVID-19](#), including among younger and non-vulnerable groups.

Figure 4: Distribution of confirmed COVID-19 deaths by age by epidemiological week reported, combined data from WHO Case Report Form and Weekly Aggregate Surveillance Systems as of 18 October 2020 (n = 459 943).

Gender distribution

Our overall data show that men and women each comprise 50% of cases; however, this proportion varies greatly between countries. A higher proportion of cases tends to be observed among men in countries where men are frequently exposed outside the household as a result of economic factors, or have differential access to testing and healthcare. In countries where women are involved in healthcare and social careers, the proportion of confirmed COVID-19 cases is higher. These gender differentials can also vary among age groups.

There is a notable difference in the death rate between sexes, with males accounting for 59% of deaths recorded. Differences in risks of exposure, behavior and risk perception, such as smoking and healthcare-seeking behaviors, as well as differences in some co-morbid conditions, may impact the outcomes of COVID-19 and contribute to male female differences in disease severity.

Situation by WHO Region

African Region

The African Region continued a four-week trend with a gradual increase in the number of new cases reported in the past 7 days (Figure 5), reporting almost 33 000 new cases – 1% of new global cases in the past week. Although the number of new cases has increased slightly, the number of new reported deaths has continued to decline since a spike was observed three weeks ago following the retrospective capturing of a large number of deaths in South Africa. South Africa, Kenya, and Ethiopia continue to report the highest numbers of new cases, while the highest number of new deaths per million population in the region was reported by South Africa (6 new cases per million population).

In Nigeria, after a peak in cases at the end of June and in July, weekly new cases have decreased gradually since September. In the past week, 923 new confirmed cases (4 cases per million population) were reported, while deaths have remained relatively low. Nigeria has a relatively low testing rate and is currently conducting 1.2 diagnostic tests per 10 000 population per week. The test positivity rate has remained relatively stable for the last 7 weeks and is currently 4%.

This past week Uganda recorded a new highest daily increase in COVID-19 cases, with over 430 cases reported on 30 October and close to 1200 cases (26 cases per million population) reported during the week. With almost half of the new cases reported from the capital, Kampala remains the most affected region. From the beginning of the epidemic, a total of 862 healthcare workers have been infected and 8 have died (7% of overall cases and deaths). Health Authorities in Kampala, in collaboration with WHO, are taking a data and equity-oriented approach to the COVID-19 response and city authorities have been assessing the susceptibility of local communities to the impact of the virus with a new COVID-19 vulnerability framework.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 1 November 2020**

**See data, table and figure notes

Region of the Americas

Although the Region as a whole reported a 13% rise in cases compared with last week (Figure 6), continued declines were observed in many countries, especially in South America. The United States of America, Brazil, and Argentina continue to report the highest number of new cases, with the United States reporting a 26% increase this week to over 500 000 new cases (1650 cases per million population). The overall change in the number of new deaths being reported in the Region, a 2% increase, is much lower than the rapid rise seen in the European Region.

Colombia has now reported over 1 million cumulative cases and 31 000 cumulative deaths. Cases in Colombia peaked in the week of 10 August at 77 915 cases, dropping to 43 000 cases in the week of 28 September, but have risen in October, with 64 200 new cases (1250 cases per million population) and 1300 new deaths reported this week. Approximately 40% of cases are aged 20-39 years. Although 30% of cases are in people aged 60 years and older, this age group accounts for 76% of deaths. A total of 64% of deaths are male. As of 25 October, around 38% of hospital beds are occupied by COVID-19 patients.

In Mexico, the number of new weekly cases rose to just under 47 000 at the end of July. Although cases have fallen since then, they have remained above 30 000 per week (295 new cases per million population reported last week). On 28 October, the Ministry of Health reported that the median age of cases is 43, with Mexico City, State of Mexico, Nuevo León, Guanajuato, and Sonora reporting the highest number of cumulative cases. Mexico City has recorded 17% of cumulative cases and has the highest number of active cases (3,000 cases), followed by Nuevo León, Guanajuato, State of Mexico, and Coahuila, which all have more than 1 000 active cases. Men account for 64% of deaths, with a median age of 63 years. Based on a recent study on excess deaths, the Ministry of Health has said that as many as an additional 50 000 excess deaths can be attributed to COVID-19.

In Peru, case incidence has continued to fall since reaching a peak in the week of 17 August when there were just under 60 000 cases. In the past week, 17 000 new cases (520 cases per million population) and 370 new deaths were reported. Around 45% of cases have been reported from one department – the region of the capital Lima. The Ministry of Health reports that as of 28 October, 4.4 million people have been tested for COVID-19. As of 28 October, there are 5419 patients hospitalized for COVID-19, of which 1052 were in intensive care. The government has approved a decree extending the state of national emergency through November.

Eastern Mediterranean Region

Over the past two months, the Eastern Mediterranean Region has observed a steady increase in the number of new COVID-19 cases recorded (Figure 7), with 182 000 reported in the past week (accounting for 5% of all cases reported globally). In the past 7 days, there has been a 10% increase in the number of deaths reported with a total of 4 700 new deaths. The Region shows a mixed pattern with countries at different epidemic stages and experiencing different outcomes. Countries reporting the highest number of cases over the past week include the Islamic Republic of Iran, Morocco and Iraq, all reporting over 550 new cases per 1 million population in the past 7 days. The countries with the highest number of new deaths per million population in the past week are Tunisia, the Islamic Republic of Iran and Jordan, with over 28 new deaths per million population.

Since early September, the incidence of COVID-19 cases and deaths in the Islamic Republic of Iran has been increasing gradually, reaching over 50 000 new cases (600 cases per million population) and 2500 new deaths in the past week. The country has the highest mortality rate overall in the Eastern Mediterranean Region with a total of 415 deaths per million population since the beginning of the pandemic. In the past week, the Islamic Republic of Iran extended public health and social measures in the capital of Tehran and across the country, as health authorities declared that they were recording a death from the virus every four minutes. Some hospitals have exceeded bed capacity to treat new patients. The closure of schools, mosques, shops, restaurants and other public institutions in Tehran, that was due to end on 26 October, will now be extended until 20 November.

Morocco has been experiencing a gradual increase in cases and deaths since the beginning of August. This past week, the country registered a new record in new cases with over 24 600 new cases and 440 new deaths. Currently, the country's COVID-19 fatality rate is around 1.7%. Casablanca-Settat is the most affected region with the majority of cases coming from the city of Casablanca. According to local authorities, this week the reproductive number has stabilized at 0.8%. The test positivity rate has raised from 11% to 16% in just three weeks. More restrictive measures have been applied in the region of Casablanca-Settat following the rise in the incidence of COVID-19. Other regions have also adopted new measures including earlier closure of shopping centres.

European Region

The European Region has seen a 22% increase in new cases and a 43% increase in new deaths in the past 7 days compared with the previous week (Figure 8). France, Italy, and the United Kingdom reported the highest numbers of new cases, although Andorra, Czechia, and Belgium reported the highest per population incidence. France accounted for the third-highest number of new cases globally, with over 275 000 cases reported in the past week (4200 cases per million population): a 27% increase from the previous week. The number of new cases has increased since August, in line with much of Europe; however, in October there has been a considerable escalation. As of 29 October, there were 24 000 hospitalizations, with 3500 in intensive care, with the Ile-de-France and Auvergne-Rhône-Alpes regions having the highest numbers of hospitalizations. The COVID-19 occupancy rate of intensive care beds is rising rapidly. The increases in indicators are most marked among people aged 65 and over. The President of the Republic announced the reinstatement of stricter public health and social measures from 30 October to 1 December.

Belgium and Italy have both seen rapid rises in cases, and reported the 2nd and 9th highest number of new cases in Europe, respectively. New cases in Belgium fell by 21% from last week to 82 500 new cases, while those in Italy rose by 72% from last week to 175 000 new cases. Despite the fall seen in Belgium, it still has one of the world's highest incidences of new cases per million population, with 7 000 new cases per million. Italy's incidence is lower at 2800 cases per million. Belgium has instituted a second phase of national containment measures. Italy and several other European countries have been experienced an increasing number of protests over government restrictions.

In Switzerland, the number of new cases has grown considerably in October, rising from fewer than 2500 new weekly cases reported from mid-April through to the end of September, and fewer than a hundred cases reported in some weeks, to 50 000 new cases in the past week. Switzerland has the fifth-highest incidence of new cases per million population in the Region (5800 cases per million population). The weekly number of hospitalizations has also risen considerably. While weekly testing rates have increased, test positivity rates have also increased from 15% to 22.5% (as of 25 October). Since the beginning of September, the median age of cases has been steadily increasing from 33 to 42 years, as of 25 October. Switzerland has progressively implemented strict public health and social measures in recent weeks, with a new range of national restrictions coming into effect on 29 October, with several cantons implementing additional measures.

South-East Asia Region

New cases and deaths in the South-East Asia Region this week have continued to decline (Figure 9). This is mainly due to a decline in reported cases in India, which contributes over 80% of all cases in the Region. Additionally, large rates of decrease have been reported seen in Nepal, Indonesia, and Bhutan. There have been over 380 000 new cases reported in the past 7 days, bringing the cumulative amount of cases to over 9.2 million.

In contrast to other countries in the region, Sri Lanka reported a 53% increase in the past 7 days from 2046 new cases to 3142 new cases (147 cases per million population). This follows a cluster detected in a garment factory on 3 October. A curfew was imposed in Colombo District and other high-risk areas from 29 October to 2 November. Additionally, active cases have been admitted to dedicated COVID-19 treatment hospitals, where 4764 patients were admitted to 37 hospitals as of 28 October. The government is also upgrading around 60 divisional hospitals as isolation and treatment centers to add more bed capacity.

Indonesia has been showing a decreasing trend of new cases for the last 4 weeks. The country reported around 24 000 new cases (88.1 per 1 million population) in the last past 7 days, and over 410 000 cumulative cases to date. WHO, in collaboration with the Ministry of Health and the National COVID-19 Task Force, has conducted a series of focus group discussions for a detailed review of challenges and possible solutions for enhancing contact tracing.

Western Pacific Region

The Western Pacific Region continues to account for the fewest cases and deaths reported globally, with declines observed in the past 2 weeks (Figure 10). There have been over 26 000 new cases (13.5 new cases per million population) reported in the past 7 days, resulting in almost 734 000 cumulative cases to date.

The Philippines continues to report the highest number of new cases (12 910 cases) and new deaths (287 deaths), representing almost 50% of new cases and 75% of new deaths in the region in the last 7 days; although incidence remains relatively low compared to other countries (117 new cases per million).

The Marshall Islands reported their first two COVID-19 cases this week on 28 October. According to the national authorities, the two cases were identified on a military base on Kwajalein Atoll, although they were not epidemiologically linked.

Over 240 new cases have been reported in China in the past 7 days, an increase of 32% compared with the previous week. A cluster of new cases related to local factories was identified in the autonomous region of Xinjiang between 24 and 28 October. Local authorities confirmed 45 cases and 138 asymptomatic cases, after 4 746 500 residents of Kashgar were tested.

Key weekly updates

- The fifth meeting of the IHR (2005) Emergency Committee on COVID-19 took place on Thursday, 29 October 2020. They advised that the pandemic still constituted a Public Health Emergency of International Concern, and urged a focus on response efforts based on lessons learned and good science. The Emergency Committee provided advice for WHO and countries to focus on in the coming months and expressed appreciation for WHO's leadership and response activities. It will reconvene in 3 months' time.
- To a significant number of people, COVID-19 poses a range of serious long-term effects, and post COVID-19 symptoms and complications have been reported in both non-hospitalised and hospitalised patients. In a [media briefing on 30 October](#), WHO Director-General Dr Tedros said "What's really concerning is the vast spectrum of symptoms that fluctuate over time, often overlap and can affect any system in the body. From fatigue, a cough and shortness of breath, to inflammation and injury of major organs - including the lungs and heart, and even neurological and psychological effects. Although we're still learning about the virus, what's clear is that this is not just a virus that kills people. While people do recover, it can be slow sometimes weeks or months and it is not always a linear route to recovery."
- [Several vaccines are now in final phase three trials](#). If proved safe and effective they will be rolled out through the [ACT Accelerator's](#) vaccine arm the [COVAX Facility](#), which is now supported by 186 countries. The COVAX Facility is speeding up the search for an effective vaccine for all countries. At the same time, it is supporting the building of manufacturing capabilities, and procuring doses ahead of time so that 2 billion doses can be fairly distributed by the end of 2021.
- Progress on gender equality has been made in all 12 key areas identified in the 1995 [Beijing Declaration and Platform for Action on Women](#) but for millions of girls and women around the world today, this visionary agenda is still far from reality. The *British Medical Journal* has commissioned [a special series of papers on "Women's Health and Gender Inequalities"](#) with support from WHO, the Human Reproduction Programme and the United Nations University International Institute for Global Health. The COVID-19 pandemic is limiting or [reversing gains made towards gender equality](#). WHO strongly urges investment in women's health and is marking the 25th anniversary of the Beijing Declaration with a number of activities.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

Global totals include 741 cases and 13 deaths reported from international conveyances.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 25 October 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

In the past week the highest number of new COVID-19 cases have been reported globally, amounting to over 2 million new cases in the past 7 days (Figure 1), the shortest intervals for this exponential increase since the start of the pandemic, while the number of new deaths is comparable to previous weeks. As of 25 October, over 42 million cases and 1.1 million deaths have been reported globally, with over 2.8 million new cases and nearly 40 000 new deaths reported over the past week.

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, 30 December 2019 through 25 October 2020**

**See [data table](#) and [figure notes](#).

For the second consecutive week the European Region accounts for the greatest proportion of reported new cases, with over 1.3 million new cases reported this past week – a 33% increase in cases compared to the previous week – contributing nearly half of all new cases reported worldwide this week (46%) (Table 1). Similarly, the number of deaths continues to increase in the region with a 35% increase from last week and accounting for nearly one third of all new deaths globally. Although not as substantial, increases in reported new cases were also observed in the Region of the Americas, Eastern-Mediterranean and African regions. Declines in cases and deaths continued to be reported in the South-East Asia region while the Western Pacific region has shown a slight decline in new cases and deaths in the past 7 days.

Despite regional variations the countries reporting the highest number of cases in the past week remain the same as the previous 3 weeks: India, the United States of America, France, Brazil and the United Kingdom.

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

Situation by WHO Region

African Region

With 32 000 new cases and 800 new deaths over the past week, the Region accounts for around 1% of new global cases and 2% of new global deaths (Table 1). South Africa, Kenya, and Ethiopia continue to report the highest numbers of new cases. The Region shows a mixed pattern with countries at different epidemic stages and experiencing different outcomes. Despite this, COVID-19 continues to contribute an added burden to public health, strained already stretched health systems and caused socio-economic pressures.

Cases in Ethiopia have declined from peaks in August when there were over 10 000 cases a week, to just over 4 400 new cases reported in the past week (38 new cases per 1 million population), a 12% decrease compared to the previous 7 days. The number of new cases in Ethiopia are the third highest in the WHO African region. Deaths in the country have increased slightly (6%) in the past week although overall numbers remain low (n 73) and the rate of new deaths is less than one (0.6) per 1 million population. Ethiopia, as well as other countries in the Horn of Africa, are facing a triple threat of floods from unusually heavy rains, desert locust crop destruction and the impacts of COVID-19-all threatening food security.

With 4 594 new cases over the past week (85 new cases per 1 million population), a 51% increase from last week, Kenya is now reporting the second highest numbers of new cases in the Region and has witnessed a dramatic rise since the week of 28 September when there were only 1 000 new cases reported. It is just shy of its previous peak at the end of July, when there were 4 700 new cases. Although deaths have increased at a much lower rate (9%) and new deaths are just over one per 1 million population (1.3). Oxygen is one of the most essential medicines for saving patients with COVID-19, as well as many other conditions. One of the main barriers to medical oxygen is the high transport costs of the cylinders to the health facilities. In Kenya, a private sector company has positioned oxygen plants near clusters of health facilities and uses a milk delivery system to deliver oxygen to more than 140 clinics. [WHO is committed to working in solidarity with all governments, partners and the private sector to scale up sustainable oxygen supply.](#)

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 25 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Region of the Americas reported 880 000 new cases (31% of the global total) and 17 000 new deaths (43% of the global total) over the past week. The United States, Brazil, and Argentina continue to report the highest number of new cases (78% of regional new cases) and new deaths (67% of regional new deaths) in the Region.

The number of new weekly cases in the United States has risen since the week beginning 7 September, when there were 240 000 confirmed cases, to over 400 000 confirmed cases over the past week. Cases are now approaching the previous epidemic peak in July. At 1 318 new cases per million population, the incidence is lower in comparison to several European countries, such as the United Kingdom (2 200 cases per million) and France (3 300 cases per million). According to a [US CDC report](#), the number of deaths from COVID-19 might underestimate the total impact of the pandemic on mortality, with an estimated 300 000 excess deaths occurring from late January through 3 October 2020, of which 200 000 excess deaths can be attributed to COVID-19.

Colombia has reported just over 1 million cumulative cases since the start of the pandemic, with the number of weekly new cases remaining stable with approximately 53 000 new cases (1 053 new cases per 1 million population) and 1 100 new deaths (23 new deaths per 1 million population) reported this week. Cases in Colombia peaked in the week of 10 August at 77 915 cases, dropping to 43 000 cases in the week of 28 September, but have risen in October.

In the week beginning 28 September, Canada exceeded its previous peak of roughly 12 000 new cases per week observed in late April. In October the number of cases has continued to rise, with over 17 000 new cases in the last week (467 new cases per 1 million population). The number of new deaths per week has also risen in October, with 166 deaths reported for the past week, although these numbers are far lower than they were in April and May when over 1 000 weekly new deaths were reported. Quebec and Ontario, which account for approximately 60% of the population of Canada, account for nearly 80% of cases. There have been reports suggesting that this rise may be partly attributable to social gatherings during Thanksgiving, which was celebrated in Canada on 12 October.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 25 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

In the past 7 days there have been 159 000 new cases and 4 000 deaths reported in the Eastern Mediterranean region. This represents a 6% increase in cases from last week and there has been a steady increasing trend seen in the region over the past two months. While Iran continues to report the highest number of new cases in the region, the highest number of new cases per 1 million population is seen in Jordan, while the highest new deaths and new deaths per 1 million population remain highest in Iran.

Jordan has reported an acceleration of new cases this past week and reached a peak of reported daily new cases in the past seven days. Bahrain reports the second highest new cases per 1 million population (1 413) and the highest cumulative cases of 47 001 per 1 million population. Increased public health and safety measures are seen throughout the country and the Ministry of Health for the Kingdom of Bahrain have recently published two new guidance documents, the first addressing health requirements to be applied in establishments serving shisha to contain and prevent the spread of the Coronavirus (COVID-19) and the other aims to establish health measures to be observed by restaurants and coffee shops to mitigate the spread of COVID-19.

While the number of new cases in Djibouti remains low, there has been an increasing trend in new cases for the past three weeks. New cases reported in the country last week showed a 480% increase (from 5 to 29) compared to three weeks ago, week beginning 28 September. This week Djibouti reported 78 new cases, a 169% increase from the previous week. These steady increases in new cases are not at previous peaks seen in June, when there were 975 cases in the first week of June, but are still of concern. As a result the Ministry of Health announced they will be closing land borders from 20 October for 15 days.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 25 October 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

The number of new cases and deaths reported in the European region are increasing exponentially, with 36% and 37% increase in cases and deaths respectively compared to the previous week, the highest percentage increase reported in a single week in the region. Although the number of deaths is gradually increasing, the proportion of deaths to cases remains relatively low, compared to the early phase of the pandemic in the spring.

Approximately 1.3 million cases and 11 700 deaths were reported in the last 7 days, accounting for 46% and 30% respectively of the total number of cases and deaths reported globally. France accounted for the greatest number of new cases, over 200 000 cases, reported in the past 7 days. In the last week, hospitalizations due to COVID-19 and ICU occupancy increased in 21 countries across the region, compared to the previous week, however, current figures represent about 25% of the numbers reported during the peak level early in the pandemic. Based on surveillance data reported, an estimated 18% of reported COVID-19 cases have been hospitalized, with 7% of hospitalized patients requiring ICU and/or respiratory support.

In the United Kingdom, new cases have increased by 30% in the past week. The number of hospitalizations in Wales has sharply increased in the last week, increasing the pressure on frontline staff. There was also a steep increase in the number of ICU admissions among COVID-19 cases aged over 65 years old in England. Other countries reporting high hospitalization rates include Czechia, where new deaths per 1 million population are currently the highest (67) since the start of the pandemic and hospitals are expected to be at maximum capacity by mid-November and Italy where hospitals in Milan are stretched to capacity and temporary clinics have been reopened to manage the burden on the health system.

In the last week, Slovenia reported their highest daily increase in the number of new cases, 1 964, the rapid rise in cases has resulted in the health care system being stretched to capacity. To reduce transmission, the country was split into red and orange zones based on reported case numbers and Public Health and Social Measures were implemented accordingly..

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 25 October 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

A continued declining trend in new cases and deaths was observed in the South-East Asia this week, this decline in new cases and deaths has been a weekly trend for the past five weeks with the largest decrease in new cases (decrease of 13%) and deaths (decrease of 16%) seen in the past 7 days. Steady decreases in cases have been seen in the past month in India, Indonesia, Myanmar, Maldives and Bhutan with other countries in the region continuing to fluctuate.

The only country in the region this week to report a substantial increase in new cases has been Sri Lanka reporting 2 046 new cases (96 new cases per 1 million population) compared to 847 new cases (40 new cases per 1 million population) last week. In an effort to decrease the burden at one of its largest hospitals, government authorities have decided to restrict the number of all outpatients patients visiting the Colombo National Hospital. As an alternative a landline and mobile service to obtain medicines at the clinics of the Colombo National Hospital.

While India is still reporting the highest number of new cases and deaths in the region, trends in these numbers for the country continue to decrease. India have reported 370 260 new cases (268 new cases per 1 million population) a decrease of 16% in the past week. 4 503 new deaths (3.3 new deaths per 1 million population) were reported this week amounting to a 21% decrease in new deaths compared to the previous 7 days. With upcoming cultural events such as Diwali, the Ministry of Culture issued a detailed standard operating procedure (SOP) for cultural functions to facilitate organization of cultural events during the COVID-19 pandemic.

Sustained declining trends have also been observed in the Maldives, with new cases down 24% from last week and continuing to be seen mostly from Greater Malé region. Additionally nearly all cases belong to known and existing clusters

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 25 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

Following a three-week increase in the number of cases reported in the Western Pacific region, the number of weekly new cases decreased by 4% in the last 7 days. The decrease in the number of cases observed was predominantly driven by the decrease reported in Papua New Guinea (94% decrease) and the Philippines (23% decrease). Similarly, the number of deaths reported in the last 7 days decreased by 6%. Approximately 27 000 cases and 430 deaths were reported in the region, accounting for just 1% of the total number of cases and deaths reported globally.

The number of cases and deaths in Malaysia has consistently increased in recent weeks, and in the last 7 days, an average of 873 cases and 6 deaths were reported daily, amounting to 189 new cases and 1.3 new deaths per 1 million population. This resulted in an increase of 35% and 64% of cases and deaths respectively compared with the previous week. The rapid increase in cases and deaths is putting the public health system under immense pressure.

Despite the decrease in cases reported in the Philippines, the country accounted for about 50% of the total number of cases and 75% of the total number of deaths reported in the region in the last 7 days. Relative to the country's population, new cases (123) and new deaths (3) per 1 million population remain low compared to other countries in the region. Heavy flooding, affecting over 35 000 households have been reported in the island of Mindanao, resulting in the evacuation of more than 12 000 people. This could affect COVID-19 response measures in the region as many displaced families are staying in makeshift tents. Mindanao also continues to report new health worker infections and an overall increasing trend in COVID-19 cases.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 25 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- [“We are at a critical juncture in this pandemic We urge leaders to take immediate action, to prevent further unnecessary deaths, essential health services from collapsing and schools shutting again.”](#) stressed the WHO Director-General Dr Tedros as part of the regular press briefing on COVID-19 on 23 October. Dr Tedros expanded that as the northern hemisphere enters winter, cases are accelerating, particularly in Europe and North America. The next few months are going to be very tough and some countries are on a dangerous track. WHO is calling on governments to carry out five key actions:
 1. Assess the current outbreak situation in your country based on the latest data
 2. For those countries where cases, hospitalizations and ICU rates are rising, make the necessary adjustments and course correct as quickly as possible.
 3. Be clear and honest with the public about the status of the pandemic in your country and what is needed from every citizen to get through this pandemic together.
 4. Put systems in place to make it easier for citizens to comply with the measures that are advised.
 5. Improve contact tracing systems and focus on isolating all cases and quarantining contacts, to avoid mandatory stay at home orders for everyone.
- WHO has updated its [draft landscape of COVID-19 candidate vaccines](#), which lists 44 candidate vaccines in clinical evaluation. At a [press briefing](#) last week, Dr Soumya Swaminathan, WHO Chief Scientist, said “We're looking at the beginning of next year really to start seeing data for many of the trials though we may see one or two before the end of the year but the majority will start reporting in early 2021. Many companies are already manufacturing several million doses so as soon as the results are out, if it's promising, companies will be able to start providing those doses to the COVAX facility which will then distribute based on the fair allocation framework that we have developed ”
- WHO has published an [assessment tool for laboratories implementing SARS-CoV-2 testing](#) to assess the capacity of laboratories that have implemented or intend to implement testing for SARS-CoV-2, the virus that causes coronavirus disease (COVID-19).
- The 10th annual global celebration of [Global Media and Information Literacy \(MIL\) Week](#) will take place from 24 to 31 October 2020, under the theme “Resisting Disinformation: Media and Information Literacy for everyone and, by everyone”. Through Global MIL Week, UNESCO and WHO are joining forces to [tackle disinformation and misinformation](#). WHO and the Wikimedia Foundation, the nonprofit that administers [Wikipedia](#), also [announced a collaboration](#) to expand the public's access to the latest and most reliable information about COVID-19.
- The [World Health Summit](#), a leading global health conference and network of civil society, academia, politics and the private sector, will take place this week as a fully digital, interactive conference with a free-to-view [programme](#). As part of this, a new book, [Health: A Political Choice Act Now, Together](#), has been launched that calls on world leaders and politicians to unite in their response to the COVID-19 pandemic and other threats to health and the global economy.
- As many countries prepare to celebrate the Day of the Dead or All Souls Day on 2 November, [WHO reminds people](#) of the importance of physical distancing, mask wearing, hand hygiene, coughing safely into your arm, avoiding crowds and meeting people outside where possible and when you have to be inside with others open windows and ensure good ventilation with non-recirculating air.

Table 2. Number of COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, as of 25 October 2020**

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines

on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

COVID-19 Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 18 October 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

The incidence of new COVID-19 cases has continued to accelerate, while the incidence of new deaths has remained relatively stable (Figure 1). As of 18 October, over 40 million cases and 1.1 million deaths have been reported globally, with over 2.4 million new cases and 36 000 new deaths reported over the past week.

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, 30 December 2019 through 18 October 2020**

**See [data table and figure notes](#).

The European Region has continued to report a rapid increase in cases and deaths, with over 927 000 new cases reported this past week – a 25% weekly increase in cases compared to the previous week – contributing 38% of all new cases reported worldwide (Table 1). Similarly, the number of deaths continues to climb with a 29% increase from last week. Increases, although more gradual, were also observed in the African, Eastern-Mediterranean and Western Pacific Regions. Declines continued to be reported in the Region of the Americas and the South-East Asia Region; although the incidence of new infections remains high, and collectively these two regions contribute over half of new cases and deaths observed globally.

The countries reporting the highest number of cases in the past week remain the same as last week: India, the United States of America, France, Brazil and the United Kingdom.

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

Situation by WHO Region

African Region

Continuing trends in the previous week, the Region reported an increase in both cases and deaths in the last 7 days, with an 11% increase in new cases and an 8% increase in new deaths (Figure 3). The pattern of increasing cases continues to be driven by South Africa and Ethiopia, with Kenya, and Botswana also reporting notable increases.

The majority of countries in the region are reporting community transmission of COVID-19 (n=39; 78%), with a further 7 (14%) classifying transmission as clusters of cases (n=7; 14%), 3 (6%) as sporadic cases, and 1 (2%) as reporting no active cases.

An unusually high number of cases was reported from Botswana this week, with over 1800 cases reported in one day. This was largely attributed to a backlog of tests administered from 2–13 October, mostly from in and around the capital city of Gaborone.

South Africa has accounted for approximately 70% of deaths in the Region in the past week. The high number of deaths being reported is partially attributed to a mortality audit, and many of these deaths are retrospectively reported.

Mauritania reported a large increase from last week (12 to 80 cases), all reported from the capital, Nouakchott. Although this is a higher number of cases than Mauritania has reported in recent weeks, it remains lower than the daily numbers reported in July.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 18 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

A slight decrease in new cases was reported across the Region over the past week (Figure 4) in comparison to the previous week. The United States of America, Brazil, Argentina, Colombia and Mexico continue to register the highest number of weekly new cases in the region, while the highest incidence of new cases per million population was reported in Argentina, Bahamas, Costa Rica and Saint Martin, all with more than 1600 cases per million in the past 7 days. A marked decline in the incidence of deaths in the region continued this past week with just over 16 000 new deaths, compared with 20 000 new deaths last week. The Region, accounts for a third (n=798 794, 33%) of new cases and almost half (45%) of new deaths reported globally in the past week. Most countries and territories in the region self characterize their current transmission pattern as community transmission (n=34, 64%), with 8 (15%) classified as clusters of cases, 7 (13%) as sporadic cases, and 5 (9%) as no cases.

Argentina remains the country in the Region with the highest number of new cases and new deaths per million population with over 2000 new cases per million inhabitants in the past week. Even though the weekly incidence of new COVID-19 cases is increasing gradually, a decreasing trend in the number of new deaths has been reported in the past two weeks, dropping from 6000 deaths per week at the end of September to less than 2500 deaths in the past week.

Guatemala continues to register a gradual decline in the incidence of new cases, however, an 88% increase in new deaths (from 80 to 150 deaths) was reported the past 7 days. COVID-19 test positivity rates have also remained relatively high for the last 12 weeks with over 10% of samples testing positive. The highest incidence of cases and deaths was reported in the capital, Guatemala City, and has reached over 530 deaths per million population.

Peru has the second-highest rate of deaths per 1 million population in the Region with 1021 deaths per million inhabitants. However, in the last week, modest decreases in case and death rates continued. Some regions have reported declines of 50% and the regions of Puno, Madre de Dios, Amazonas and Moquegua registered declines of 70% in the weekly incidence of COVID-19.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 18 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

A gradual increase of new cases and deaths was reported by the Eastern Mediterranean Region over the past week (Figure 5), reaching the highest weekly incidence reported since the beginning of the pandemic, with almost 150 000 new confirmed cases from 22 countries. In the past week, The Islamic Republic of Iran, Iraq and Morocco are reported the highest number of new cases while Bahrain, Lebanon and Jordan report the highest incidence, with over 1500 new cases per million population.

A majority of the countries in the region continue to self-characterise their current transmission pattern as community transmission (n=14, 64%), with 5 countries reporting clusters of cases and sporadic cases being reported in Somalia, Djibouti and Saudi Arabia. During the past week, Tunisia updated their classification from clusters of cases to community transmission.

The Islamic Republic of Iran remains the most affected country in the region with Tehran, the capital city, being the most affected area. In this reporting period, Iran has recorded new weekly records, with over 30 000 new cases (360 cases per million population) and over 1,800 deaths (22 new deaths per million population) reported, bringing cumulative counts in the country to over 534 000 cases and 30 000 deaths.

Libya has shown a surge in cases, recording over 6,000 new cases (900 cases per million population). Test positivity rates also continue to gradually increase, with approximately 1 in 4 samples tested returning a positive result.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 18 October 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

This week, the European Region again reports the highest increase in cases and deaths thus far – 25% and 29%, respectively compared to the previous week. In addition, the Region reported the greatest proportion of new cases globally (38%, n=927 433). A [media briefing by WHO Regional Director for Europe](#) highlighted that the region is currently reporting over three times more cases per day compared to the April peak, with hospital admissions rising, although the number of daily deaths remains five times lower than they were in April.

France, the United Kingdom, the Russian Federation, Czechia and Italy continue to report a high incidence of new cases. Collectively, these five countries contribute to over half of all reported cases this week in the Region.

A majority of the countries in the region self-characterise their current transmission pattern as community transmission (n=34, 55%), with a further 20 (33%) countries reporting clusters of cases, 4 (6%) clusters of cases, 3 (<1%) no cases, and one pending classification. During the past week North Macedonia updated their classification from clusters of cases to community transmission.

Slovenia reported a 150% increase in cases this week (n=4890) – the highest one-week increase the country has experienced so far. In addition, Slovenia reported 1924 deaths, compared to only one death last week. In response to this recent increase in cases and deaths, as of 19 October, the Slovenian government has declared a 30-day state of emergency with a daily curfew.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 18 October 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

Overall, the region continues to show a decline in cases and deaths (Figure 7), with Nepal being the only country which reported an increase in both new weekly cases (12%) and new deaths (31%) in comparison to the previous week. Nepal reported 810 new cases per one million population, the highest in the region, followed by the Maldives (590) and India (319). Most countries in the region self-characterise their current transmission pattern as cluster of cases (n=6, 55%), with two countries reporting community transmission and a further two reporting sporadic cases.

Bangladesh reported an 8% increase in new weekly cases. Among the 386 086 cases reported as of 16 October, the majority (81%) were adults aged 21–60 years, and almost three-quarters (72%) were male. During the same timeframe, the country has conducted 2.13 million diagnostic tests, or 12 900 tests per million population.

Myanmar reported a 6% increase in new weekly deaths compared to last week. The majority of the cases and deaths continue to be reported from Yangon Region. Here, the Government has further extended stay at home orders for 44 townships from 8–21 October. On 3 October, Myanmar published standard operating procedures for testing of COVID-19 with antigen-based rapid diagnostic kits, and began using these in Yangon Region on 29 September, followed by other regions and states.

Thailand continues to report relatively low numbers of cases. The country has become one of the first countries in the world to complete an assessment of [how its health system has so far responded to COVID-19](#). The review highlights success factors and provides recommendations across nine areas, or “pillars” of the national response.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 18 October 2020**

**See data, table and figure notes

Western Pacific Region

Overall, one percent of all new weekly cases and deaths were reported from the Western-Pacific Region. The region reported an 8% increase in new weekly cases and 27% decrease in new weekly deaths as compared to the previous week. The majority of new cases continue to be reported from the Philippines, Malaysia and Japan. Whereas French Polynesia and Guam reported the highest incidence of new cases – 3713 and 3258 new cases per one million inhabitants, respectively. Papua New Guinea reported an increase of over 200% in weekly cases as compared to the previous week, with 31 new cases and 581 total confirmed cases.

Only two out of countries and territories in the region self-characterize their current transmission pattern as community transmission, with a further 9 (24%) countries reporting clusters of cases, and 7 (18%) countries reporting sporadic cases. The majority (n=19, 50%) of countries and territories report no active cases, and one territory is pending classification.

Malaysia reported a 51% increase in cases and deaths as compared to last week, with the majority of cases reported from Sabah State. The Ministry of Health have taken several measures reduce transmission and increasing test capacity in the state – daily RT-PCR tests increased from 1350 in July to 2600 as of 17 October.

Wallis and Futuna, reported its first positive case of COVID-19 to WHO on 19 October. As this falls outside of the reporting period of this update, the island territory will be reflected in next week's update.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 18 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- **Therapeutics:** [The Solidarity Therapeutics Trial have produced conclusive evidence on whether selected repurposed drugs are effective for COVID-19](#). Interim results from the Solidarity Therapeutics Trial, coordinated by WHO, indicate that remdesivir, hydroxychloroquine, lopinavir/ritonavir and interferon regimens appear to have little or no effect on 28-day mortality or the in-hospital course of COVID-19 among hospitalised patients.
- **A call of Solidarity:** [Kim Sledge and the World We Want have partnered with WHO Foundation to re-record the unity anthem, “We Are Family”, in response to COVID-19 and to bring focus on global public health needs](#). A special edition cover of Sister Sledge’s hit “We Are Family” will be released in a new and inspiring call for global solidarity to respond to the COVID-19 pandemic and to generate proceeds to address the most pressing global health challenges of our time. In support of the song’s release, people worldwide are invited to submit videos of themselves singing We Are Family for inclusion in a compilation video for release on 7 December 2020.
- **Briefings:** WHO Director-General Dr Tedros, in his regular [media briefing on 12 October](#), expressed concern around the concept of reaching so-called “herd immunity” by the letting the virus spread – “never in the history of public health has herd immunity been used as a strategy for responding to an outbreak, let alone a pandemic. It is scientifically and ethically problematic”. Furthermore, in a [media briefing on 16 October](#), Dr Tedros highlighted the rising number of cases of COVID-19 globally, especially in Europe where, although the number of deaths reported is much lower than in March, hospitalisations are increasing.
- **Health System Strengthening:** WHO published a [Handbook for public health capacity-building at ground crossings and cross-border collaboration](#). The objectives of the handbook are to introduce principles of strategic risk assessment for prioritizing preparedness and response capacity building; highlight issues to consider when selecting ground crossings for designation under the International Health Regulations (2005, IHR); and, support the establishment and maintenance of cross-border collaboration to improve coordination and communication.
- **Food security, public health and livelihoods:** On 13 October, WHO with the International Labour Organization (ILO), Food and Agriculture Organization (FAO), and the International Fund for Agriculture Development (IFAD) released a [joint statement on the Impact of COVID-19 on people's livelihoods, their health and our food systems](#). The pandemic has been affecting the entire food system and has laid bare its fragility. Border closures, trade restrictions and confinement measures have been preventing farmers from accessing markets, including for buying inputs and selling their produce, and agricultural workers from harvesting crops, thus disrupting domestic and international food supply chains and reducing access to healthy, safe and diverse diets. According to the [policy brief](#) published by the United Nations, in the long run, we face possible disruptions to the functioning of food systems, with severe consequences for health and nutrition.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines

on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Coronavirus disease (COVID-19)

Data as received by WHO from national authorities, as of 11 October 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)
- This will be the final Weekly Epidemiology Update published on a Monday, beginning next week 20 October, these updates will be published on a Tuesday.

Global epidemiological situation

Since the last [Weekly Epidemiological Update](#) issued on 5 October, over 2.2 million new cases and 39,000 deaths of COVID-19 have been reported across all six WHO regions. This is the highest number of reported cases so far in a single week.

From 30 December through 11 October, over 37 million COVID-19 cases and 1 million deaths have been reported globally. Nearly half of these cases (48%) and deaths (55%) continue to be reported in the Region of the Americas with the United States of America, Brazil and Argentina accounting for the greatest numbers of new cases and deaths in the region.

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, 30 December 2019 through 11 October 2020**

**See [data table](#) and [figure notes](#).

By WHO region, the European Region reported the greatest increase (34%) in cases in the past week while the African Region reported a substantial rise in deaths, with a 27% increase compared to the previous week. Within the African Region, South Africa continues to register more than half (56%, 690 896) of all reported confirmed cases.

For the third week in a row, the South-East Asia Region reported a decline in new cases and deaths, 6% and 8% respectively, compared to the previous week. The decline is mainly due to decreases in reported cases in India and Bangladesh.

For the second week in a row, the Regions of the Eastern Mediterranean and the Western Pacific reported increases in cases and deaths.

Overall, during the reporting period, all the Regions showed an increase in cases except the South-East Asia Region.

Countries reporting the highest number of cases in the past seven days include; India, the United States of America, Brazil, the United Kingdom and France.

Additional Region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, as of 11 October 2020**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days*	Cumulative deaths (%)
Americas	804 735 (35%)	6%	17 794 771 (48%)	20 509 (52%)	-5%	588 867 (55%)
South-East Asia	575 763 (25%)	-6%	7 911 036 (21%)	7 750 (20%)	-8%	126 917 (12%)
Europe	694 275 (31%)	34%	6 918 265 (19%)	6 172 (16%)	16%	246 709 (23%)

Situation by WHO Region

African Region

Although the Region had seen a slow but continuous decline in newly-reported cases since mid-July, there were 11% more cases reported in the last 7 days compared to the prior week, reaching a total of over 1 200 000 cases (Figure 1, Figure 3). The current figures in the region represent 1% of confirmed COVID-19 cases and 3% of deaths reported worldwide in the past week. The increase in the number of newly-confirmed cases is partially attributed to the higher number of countries reporting an increase in cases (21 countries), compared to the previous week (14 countries). Although there are a greater number of countries reporting increases, the pattern of increasing cases is driven by South Africa and Ethiopia, which continue to report the highest numbers of new cases in the last 7 days, followed by Kenya, Uganda, and Algeria. Continuing the trend from last week, the number of reported deaths increased this week with South Africa accounting for the majority of the new deaths in the Region (74%).

The current transmission pattern in the majority of the 47 Member States in the African Region is reported as community transmission (n=39, 83%), with five reporting clusters of cases, and only Seychelles, Mauritius and Eritrea currently reporting sporadic cases.

South Sudan has reported a decrease in the number of newly-reported cases with an epidemiological link, with 29% in the past week, compared to 67% the week prior. This is attributed to a decrease in the proportion of cases that have been detected at a border crossing, where a history of travel can inform an epidemiological link.

This past week, Mozambique registered 795 new cases (25 per million population) bringing the total figure to almost 10 000 cases. Nevertheless, the country has registered a gradual decline over the last three weeks including a 39 and 40% decrease in new cases and deaths respectively in the past week, suggesting the epidemic may be slowing down in the country. While the number of tests per 1000 inhabitants has remained quite stable at 0.3 over the last 10 weeks, the test positivity rate has dropped this week to 9%. Schools have reopened with special measures to prevent further spread of the virus.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 11 October 2020**

Region of the Americas

The Region of the Americas reported over 800 000 new cases in the last seven days, a 6% increase in the number of new cases in the past week which is a bigger increase than the increase reported in the previous week. greater change than the week prior. The United States of America, Brazil, Argentina, Mexico, and Colombia registered the highest number of newly- reported cases ik.

The Region also continues to account for a majority of all deaths reported globally in the past week (n=20 500, 52%). Mexico, the United States of America, Brazil, Argentina and Colombia registered the highest number of new deaths.

This past week, the United States of America reported the largest increase in newly -reported cases since early August, with over 327 000 cases reported. Ten of the 50 states reported the highest one-day increases in cases since their first reported case, including many in the Midwest and the Southwest, and three states reported their largest-ever one-day increase in new deaths.

The number of newly- reported cases has been increasing in Canada since mid-September, with an increase of 26.7% cases and 14.3% deaths in the past week. Most of the cases and deaths were reported in Québec and Ontario. Outbreaks in long-term care and retirement residences continue to account for most outbreaks in Canada to date. Since mid-July, incidence rates in those 20 to 39 years of age have remained consistently higher than all other age groups. Since mid-September, an increasing trend in the daily number of cases 20 to 39 years of age hospitalized has been observed.

Costa Rica, with the second- highest incidence of cases per million population in the Region s r, has now reached over 86 000 cases and over 1 000 deaths. During the last 5 weeks, the country had reached a plateau with comparable figures of reported cases and deaths. The country has reported over 107 COVID-19 hospitalizations per million inhabitants of which over a third of them are in intensive care units.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 11 October 2020**

**See data, table and figure notes

Eastern Mediterranean Region

In the Eastern Mediterranean region the weekly number of new cases and deaths have increased by 10% and 13% respectively in comparison to the previous week. The Islamic Republic of Iran is the worst affected country in the region, accounting for 20% of all new cases reported this week.

The number of new cases in Oman have more than doubled in the last week (from approximately 2 600 to over 5 500) amounting to an increase of more than 60%. This past week a 100 bed field hospital for COVID-19 patients along with an isolation center in the city of Sohar, the capital and largest city of the Al Batinah North Governorate and another isolation ward in Sur Hospital in the South Sharqiya region were opened to help mitigate the rising number of COVID-19 cases in the country.

In Tunisia, there have been peak new cases (over 2 500) and deaths (over 40) also reported this week and the country plans to impose increased public health and safety measures including bans on gatherings, cutting public sector work hours and imposing curfews in an effort to interrupt transmission.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 11 October 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

The Region registered the highest weekly incidence of COVID-19 cases since the beginning of the pandemic with almost 700 000 new cases reported. The weekly incidence in cases and deaths increased by 34% and 16% respectively in comparison to the previous week (Figure 6). The Region is the second most active, contributing almost a third (n=694 275, 31%) of new weekly cases reported globally. The United Kingdom, France, the Russian Federation and Spain account for over half of all new cases reported in the region (n= 355 455, 51%).

Latvia, Faroe Islands and Iceland have reported the greatest percentage increase in new cases in the past week while a marked decrease was reported in Isle of Man, Malta and Spain. The majority of the countries in the region self-characterise their current transmission pattern as community transmission (n=30, 56%) or clusters of cases (n=20, 37%) with only Liechtenstein, Monaco and the Holy See reporting sporadic transmission.

Spain, with over 50 000 cases reported in the past week, is showing a noticeable decline in the weekly incidence of cases and deaths of 24% and 19% respectively. In the past week, over 740 000 polymerase chain reaction (PCR) diagnostic tests were carried out (16 tests per 1000 inhabitants per week). As of 08 of October, the bed occupancy in intensive care unit ranged between 7% and 39% across all regions. The incidence of cases and deaths in Poland increased this week by 93% and 104% respectively compared to the previous week, with almost 23 500 new cases and 370 deaths reported. Poland is tightening public health and social measures in response to these marked increases in an effort to avoid another lockdown. A coordination hospital will be created in each provide to manage the surge in COVID-19 patients.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 11 October 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

The gradual decline in incidence of cases and deaths in the South East Asia Region continued during the past week. The Region, nevertheless, remains among the most active, accounting for 25% of cases and 20% of deaths newly reported globally in the past seven days (Figure 7).

The countries reporting the highest number of new cases in the South-East Asia Region continue to be India, Indonesia and Nepal, while Sri Lanka and Bhutan are showing the highest increase in the proportion of new cases in the past week compared to the previous week. Across the ten countries in the region, only Myanmar and Nepal reported an increase in the number of new deaths in the past week compared to the previous week. The countries reporting the highest number of new deaths per million population are India and Myanmar, with 5 and 4 new deaths per million population respectively. In contrast to the other regions with currently high case incidence, most of the 10 Member States in the South-East Asian Region self-report their current transmission pattern as either clusters of cases (n=6) or sporadic cases (n=2), with only Bangladesh and Indonesia currently reporting community transmission.

Sri Lanka reported over 1200 new confirmed cases in the past epidemiological week, a substantial increase compared to the 46 cases confirmed the previous reporting week. In a recent development, a large cluster of cases (831 cases as on 7 October 2020) was reported in an apparel manufacturing factory in Gamphana district about 50 km from Colombo. The exact epidemiological link is currently under investigation

The reported number of cases increased rapidly in Nepal in the past week, with over 21 000 new cases and 86 new deaths reported. Although the test positivity rate has raised from 5 to 15% in just 8 weeks, there has also been an expansion in testing activity, which is currently around 3 samples tested / 1000 persons per week.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 11 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

The Western Pacific region accounts for the least number of reported cases globally this week, however the region has experienced an increase of 6% in newly- reported cases and a 26% increase in reported deaths in the past seven days.

New cases in the Philippines have stabilized over the past 3 weeks with around 18 000 cases reported weekly, lower than the peak of around 30 000 weekly new cases in early to mid- August however it does continue to account for the greatest number of new cases in the region. Reports suggest clustering of cases has occurred in several workplaces in Davao Region following the easing of lockdown restrictions under the modified general community quarantine and reopening of the economy measures, with most of the clusters reported in 12 establishments. As of October 12, the total number of cases in Davao Region is 3,743 with 686 cases reported in the past two weeks and Davao City (the capital) contributing 65% of the total cases in the region. There are also reports of near capacity utilization of ICU and Ward beds, in the major hospital in the region last week.

In French Polynesia, there were peak new cases this week, a 62% increase from last week, with reports suggesting most cases were detected from the main island of Tahiti, with cases spreading to adjacent islands of Moorea and even reaching several outer islands, including Raivavae, Arutua, and Nuku Hiva. Deaths in French Polynesia remain low and have not increased in the past week. The positivity rate of COVID-19 tests is currently high, at 26.3%, however only symptomatic persons are being tested.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 11 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Surveillance update of the impact of COVID-19 on health workers

Delivering the diagnostic, treatment, and vaccine interventions for COVID-19, while maintaining essential health services, requires a healthy, trained, competent, equipped, protected, well-managed, and appropriately staffed multi-disciplinary healthcare workforce. Health and social care workers both salaried and volunteer, face multiple challenges due to COVID-19, leading to either an increased workload or absences from work. Challenges include: pre-existing workforce shortages; repurposing of staff to the COVID-19 response; infections and deaths; quarantine and self-isolation requirements; stress and burn-out; shortages of critical equipment and supplies, such as personal protective equipment (PPE); inadequate training; labour disputes; and having to care for infected friends and family. A comprehensive assessment of the impact of COVID-19 on health and social care workers should utilize standardized measurements and reporting to adequately qualify the impact. Internationally agreed indicators exist, and they form part of WHO's ongoing surveillance and communications activities. Health and social workers, in contact with COVID-19 patients and/or who care for COVID-19 patients, are at a higher risk of infection than the general population. Mitigating and reducing this risk, and following WHO guidance (see below), is essential.

WHO collects case-based surveillance data from Member States using [Case Report Forms \(CRFs\)](#) via the WHO global surveillance for COVID-19. As of 14 September 2020, the CRF database contained 8 233 444 forms, representing 28.4% of the cases recorded globally by that date. The CRFs facilitate a descriptive analysis of infections, hospitalizations, clinical outcomes, and sub-population analysis (such as occupation notified as health worker).

An analysis of health worker (HW) information was conducted on 281 083 HWs from amongst 1 932 941 CRFs that indicated HW¹ status (23.5% of all CRFs) from 83 countries. These data, covering primarily European and American countries, estimate that around 14% of COVID-19 cases reported to WHO are identified as occurring in health workers. There are wide differences in the reported proportion of HW affected between countries. The overall mean estimate of infections amongst HWs illustrates a clear over representation of cases, given that they represent less than 3% of the population, globally, and less than 8% on average in high income countries.

Encouragingly, the data indicate that there has been a substantial decline in HW infection since the beginning of the epidemic, independent of the overall change in incidence of cases. In many countries, this is likely due to the increased availability of PPE and better adherence to infection prevention and control (IPC) guidance. Figure 9 shows monthly trends in HW infection, using data from selected European countries². The trends show that in the last 3 months prior to the analysis the proportion of cases amongst HWs was closer to their share of the general population.

¹ For the purposes of the case-based surveillance, 'health workers' were defined as those working "any job in a health care setting".

² Data covering only countries reporting at least 70% of cases in CRF, with at least 70% of CRFs having a known HW status, with at least 500 HW infections reported.

Figure 9. Share of health workers amongst total reported infections in selected countries, by month of reporting, March-August 2020

The mean age of COVID-19 cases of HWs was 40 years (IQR 31-49), lower than the mean age of non-HWs, 46 years (IQR 31-60). The distribution of HW infections in women (67%) and men (29%) (4% unknown sex) is proportionate to the global share of women and men in the health workforce. This is notably different from the ratio of infections in females versus males for the general population, where males account for 53% of cases.

WHO compared the proportions of COVID-19 case-patients with comorbidities, hospitalization and death as an outcome by age categories and sex in HWs and non-HWs, using information from five countries in the Americas and Europe with complete data. A total of 13% (n = 37 446) of HW case-patients reported underlying comorbidities (Figure 10), including diabetes and cardiovascular diseases, such as hypertension. Of HW case-patients, 5% (n = 15 141) required hospitalization (Figure 11), and of these, 5.3% (n = 799) required oxygen therapy. Overall, 0.5% (n = 1417) of the HW cases were fatal (Figure 12). As per the data analyzed, HWs showed a lower proportion of comorbidities, hospitalizations and deaths than non-HWs, even when accounting for age and sex differences between the two populations (see figures below). These differences were especially pronounced for those aged 50 years and above.

Further analyses are warranted to explain differences seen between infections in health-workers and the general public.

WHO guidance and resources:

To support health and social care workers and health-facilities in managing the COVID-19 pandemic, WHO has produced guidance on [Risk assessment and management of exposure of health care workers](#), [Infection prevention and control during health care when coronavirus disease \(COVID-19\) is suspected or confirmed](#), [Advice on the use of masks in the context of COVID-19](#), [Rational use of PPE for COVID-19 and considerations during severe shortages](#), [IPC in long-term care facilities](#), [Rights, roles and responsibilities of health workers, including key considerations for occupational safety and health](#); the guidance is being continuously revised as new scientific information emerges. WHO has also produced a [surveillance protocol targeting health workers who are found positive to COVID-19](#); as well as a [WHO Academy online learning app for COVID-19](#).

Figure 10. Proportion of COVID-19 cases with comorbidities by age group and sex, amongst health workers and non-health workers (n=1 159 169)

Figure 11. Proportion of hospitalized COVID-19 cases by age group and sex, amongst health workers and non-health workers (n=1 159 169)

Figure 12. Proportion of fatal COVID-19 cases by age group and sex, amongst health workers and non-health workers (n=1 159 169)

Key weekly updates

- At [WHO's Executive Board meeting](#), WHO Director-General Dr Tedros highlighted some of WHO's key actions over the course of the pandemic:
 - Declaring a Public Health Emergency of International (PHEIC) Concern on 30 January;
 - Publishing the first Strategic Preparedness and Response Plan 4 days later;
 - Developing and publishing the first protocol for developing a PCR test and assisting in the development of the first diagnostic test;
 - Producing and shipping the diagnostic tests within a month of declaring the outbreak, with millions of tests distributed to more than 150 countries since then;
 - Publishing more than 400 guidance documents for individuals, communities, schools, businesses, industries, health workers, health facilities and governments;
 - Building country capacity by providing free training in 133 COVID-19 courses on [OpenWHO.org](#);
 - Working closely with governments to write national plans and identify needs, and to match those needs with more than 600 partners and 74 donors through the [COVID-19 Partners Platform](#);
 - Sending expert missions to more than 130 countries to provide operational and technical support;
 - Sourcing, validating, purchasing and delivering masks, gloves, respirators, gowns, goggles, swabs, tests, reagents, thermometers, oxygen concentrators, ventilators and more, to 177 countries and territories;
 - Enrolling more than 12,000 patients in the [WHO Solidarity Therapeutics Trial](#), in nearly 500 hospitals in 29 countries; and
 - Launching the [Access to COVID-19 Tools Accelerator](#), which is working on diagnostics, treatment, vaccines and health system strengthening. It includes [COVAX](#) which is supporting the development of 9 vaccines, with more in the pipeline and aims to fairly distribute 2 billion vaccine doses by the end of 2021.
- “The pandemic must be a turning point for all of us; a catalyst for making universal health coverage a reality, and not just an aspiration”, urged Dr Tedros at a [side event of the 75th session of the United Nations General Assembly](#). According to the [WHO global pulse survey](#), 90% of countries report disruptions to essential health services since COVID-19, with low- and middle-income countries reporting the greatest difficulties.
- Close to a billion people are living with a mental disorder and 1 person dies every 40 seconds by suicide. A recent [WHO survey](#) found that the COVID-19 pandemic has disrupted or halted critical mental health services in 93% of countries worldwide while the demand for mental health is increasing. To celebrate [World Mental Health Day](#) (Saturday 10 October), WHO, in collaboration with [United for Global Mental Health](#) and the [World Federation for Mental Health](#), encouraged people from all countries to support a global movement calling for greater investment in mental health.
- More than 200,000 additional stillbirths could occur over the next 12 months in 117 low- and middle-income countries due to severe COVID-related disruptions in health care services according to [the first ever joint report on stillbirth estimates](#). Around 2 million babies are stillborn every year, with the majority of these deaths avoided with high-quality care antenatally and during birth.

- The [International Day of the Girl](#), celebrated on Sunday 11 October, focuses on the importance, power, and potential of girls around the world. COVID-19 represents a [huge challenge for adolescents and young people](#), and especially for girls and young women. Young people need to be a key part of the solution to this global crisis, working jointly with their communities and health authorities to help break the chain of infection.

Table 2. Number of COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, as of 11 October 2020**

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines

on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Coronavirus disease (COVID-19)

Data as received by WHO from national authorities, as of 04 October 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

The number of new cases per week has remained stable at 2 million for the past three weeks (Figure 1), with the cumulative total of over 34.8 million cases. Over 1 million deaths have now been reported globally, of which the majority were reported in the Region of the Americas (55%), followed by Europe (23%). In the past week, the regions of the Americas, South-East Asia, and Europe account for 91% of new cases. Five countries (namely India, the United States of America, Brazil, Argentina and France) reported 60% of new global cases this past week, while Israel registered the highest incidence (3717 new cases per 1 million population). Globally, the highest percentage of cases have been reported in the 25-39 age group, with approximately 50% of cases in the 25-64 age group. However, the percentage of deaths increases with age, and approximately 75% of deaths are in those aged 65 years and above.

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, 30 December 2019 through 04 October 2020**

**See [data table](#) and [figure notes](#).

Although globally the number of new cases was similar to the number of cases in the previous week, there is considerable variation on a country- by-country basis. In several countries, the number of new cases is rising again, and in many (most notably within the European Region) the second wave is exceeding previous peaks; this can be partly attributed to enhancements in surveillance capacities over time. In other countries we have seen a gradual decline in new cases from earlier peaks in August, for example in Brazil, Colombia and Peru. In India and the Philippines, the number of new cases appear to have stabilized, but they are still reporting high numbers. There are also examples of countries that have consistently shown an increasing incidence as their first wave continues; these include Indonesia, Iraq, and Myanmar, although Indonesia is reporting a slight drop this week. South Africa and Australia are examples of countries that have successfully managed to reduce the number of new cases and have seen large reductions from earlier peaks.

Additional region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

Situation by WHO Region

African Region

South Africa and Ethiopia continue to report the highest numbers of new cases in Africa, followed by Mozambique, Uganda, and Nigeria. Africa has seen a continuous decline in case incidence since mid-July; however, this trend is now slowing (Figure 3). For the first week since early August, the number of new deaths has risen – led by South Africa with a 29% increase in deaths in the past week.

South Africa also has the second- highest mortality rate in the Region – 11 461 deaths per 1 million population. The provinces of Gauteng and the Western Cape have reported the most cases and deaths to date; however, these regions, as well as the country itself, have maintained sustained declines in the daily incidence since the end of July. Despite this, weekly case numbers have continued to rise in less populated provinces. The country moved to Alert Level 1 as of 21 September (the least stringent of the five alert levels applied by the South African Government), with all sectors of the economy now open with strict adherence to public health protocols. A WHO surge team of experts, including infectious disease specialists and epidemiologists, is currently in South Africa, and is continuing to work with the National Department of Health.

New weekly cases have risen in Angola from 400 in the week of 7 September to 698 cases in the past week, a 74% increase, although the number of new cases has declined by 10% from the past week. Angola recently upgraded their self-reported transmission classification from ‘clusters of cases’ to ‘community transmission’. Luanda province remains the epicentre with around 90% of all cases. A total of 16 out of the 18 provinces have reported confirmed cases. WHO has trained around 90 community health mobilizers now operating across Luanda.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 4 October 2020**

**See [data, table and figure notes](#)

Region of the Americas

A similar incidence of new cases was reported across the Region over the past week (Figure 4) in comparison to previous week. The United States of America, Brazil, Argentina, Colombia, Mexico and Peru registered the highest number of weekly new cases.

The United States of America continues to record approximately 300 000 new cases per week (894 new cases per 1 million population). Declines observed over July and August have stagnated in recent weeks, with several states reporting sharp rises in case numbers – most notably in Midwest states. Canada is also showing a large increase in new cases and new deaths compared with last week, at 43% and 208% respectively. Likewise, Argentina continues to report an increase in cases and deaths, with cumulative deaths exceeding 20 000 last week after a backlog of over 3000 reported deaths from Buenos Aires. Since peaking at just over 300 000 new weekly cases in the week of 27 July, new cases in Brazil have fallen to 190 000 new cases in the past week (898 new cases per 1 million population). Weekly new cases have also fallen in Colombia and Peru.

In the Region of the Americas, as in other Regions, older persons are far more likely to experience severe disease following infection. Brazil reported that 76% of COVID-19 related deaths during February to September 2020 were in adults aged 60 years and older. In Peru, people over the age of 70 years had the highest COVID-19 mortality rates during March-May 2020 and estimates from Canada show that more than 80% of COVID-19 deaths have occurred in long-term-care facilities. WHO has published guidance on [Preventing and managing COVID-19 across long-term care services](#) with an [annex](#) providing a comprehensive set of actions for policymakers, national and local decision-makers and other actors.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 04 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

A similar incidence of new cases was reported from the Eastern Mediterranean Region over the past week (Figure 5) in comparison to previous week. Iraq, Iran, Morocco, and Lebanon are reporting the highest numbers of new cases for the past week. Iraq has reported over 20 000 cases per week since the beginning of August and this week just under 30 000 cases new cases (745 cases per 1 million population) were reported. In Jordan, case incidence has almost doubled each week for the past five weeks, with over 6600 new cases (a 90% increase on the previous week) reported last week.

Since the start of September, the Islamic Republic of Iran has shown an upward trend in weekly new cases and is reporting their highest number of new cases – 25 000 new cases (298 cases per 1 million population) – since the beginning of the pandemic.

Lebanon reported a 19% increase in new cases compared with the previous week and has one of the highest rates of new cases in the Region (1209 new cases per 1 million population). On 29 September, WHO also launched an initiative to rebuild the Ministry of Public Health's Central Drug Warehouse in Qarantina, Lebanon, which was destroyed by the Beirut port blast on 4 August.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 04 October 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

The incidence of new cases has continued to increase in the European Region overall (Figure 6). France, the Russian Federation, the United Kingdom, Spain, and Israel reported the highest numbers of new cases in the past week. The numbers of new cases and new deaths in the Russian Federation, the United Kingdom, Ukraine and several other countries in Europe are showing considerable increases compared with last week. The Netherlands, Czechia, Germany, and Italy have also reported sizable increases. Israel continues to have the highest incidence of new cases per 1 million population in the Region and globally, with over 32 000 cases reported in the past week (3717 new cases per 1 million population).

With over 1.2 million COVID-19 cases, and over 63 000 new cases in the past week (436 cases per 1 million population), the Russia Federation is reporting the second highest number of new cases in Europe and the sixth highest number globally. Russia's weekly new cases peaked at 75 000 cases in the week of 4 May, with a gradual decrease observed through late August, but rapid increases observed in the last three weeks.

In contrast to other European countries, Ukraine did not observe a large first peak, but has reported a continuous increase in new cases since mid-June. Over 27 000 new cases were reported in the past week (636 new cases per 1 million population), a 21% rise from the week before. Since the start of the outbreak, WHO has supported the Ministry of Health to further develop three key areas of its health system: health financing, service delivery, and governance. In September, WHO experts worked together with national authorities to make sure rehabilitation services are fully functional and well-integrated into health care.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 04 October 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

A gradual decline in case and deaths incidence in the South-East Asia Region continued during the past week (Figure 7). Nevertheless, the Region contributes almost a third ($n=614\,502$, 30%) of new cases reported global in the past week. At the same time, current weekly case incidence (304 per 1 million population) is markedly lower than that which is currently observed in the Americas and Europe.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 04 October 2020**

**See [data](#), [table](#) and [figure notes](#)

India, reporting over 500 000 new cases per week since late-August, again contributed the majority of incident cases in the Region (91%) and globally (27%) last week, bringing cumulative counts in the country to an excess of 6.5 million cases and 100 000 deaths (10% of the global total). Over several months, case numbers in India rose rapidly, with Maharashtra, Andhra Pradesh, Karnataka, Tamil Nadu, and Uttar Pradesh reporting the highest numbers of cases. This increase occurred with a concurrent expansion in testing activity, which has since stabilized at 7–8 million samples tested per week (or 5.2–5.8 samples tested/1000 persons/week) in the past five weeks. Weekly incidence of new cases is gradually easing, falling to 403 new cases per 1 million population (556 841 cases) this past week, after peaking three weeks ago, while test positivity rates fell marginally to 7.1%.

Indonesia is currently the second most affected country in the Region, nearing 300 000 cases to date, including over 28 000 new cases (or 103 new cases per 1 million population) in the past week. Almost 60% of cases to date have been reported from the island of Java, which includes the capital Jakarta. Suspected case numbers have risen sharply in recent weeks; however, testing capacity has thus far been unable to meet demand, with approximately 23% ($n=30\,940$ people) people tested among some 132 000 suspected cases reported on 30 September. Among four provinces that achieved a benchmark of 1 person tested/1000 population/week during September, weekly test positivity rates ranged markedly from less than 5% to over 40%, highlighting the heterogeneity in both surveillance capacity and COVID-19 activities across the island.

In Myanmar, COVID-19 incidence has risen sharply, with cumulative counts almost doubling each week since mid-August, and over 6500 new cases (or 120 new cases per 1 million population) reported in the past week. Rakhine State and the country's largest city, Yangon has reported around 75% of cases, and has been hardest hit to date, with a possibility of community transmission in areas. On 20 September, Myanmar announced a stay-home order for its biggest city Yangon.

Western Pacific Region

In the Western Pacific Region, the weekly number of new cases reported continues to fluctuate (Figure 8). The Philippines, Japan, and Malaysia are reporting the highest numbers of new cases, with Malaysia reporting an increase of 119% in new cases compared with last week.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 04 October 2020**

**See [data](#), [table](#) and [figure notes](#)

Around three-quarters (73%) of new cases in the region were from the Philippines. Although weekly new cases in the Philippines peaked in the week of 10 August, the incidence of new cases remains relatively high compared to others in the Region, with over 18 000 new cases in the past week (165 cases per 1 million population). Data as of 29 September shows that 50% of cases are in the age group 20-39 years, while 60% of deaths are in those aged 60 years and over. There is community transmission in all regions of the country, with three regions - National Capital Region, Region 3, and Region 4A – showing higher transmission intensity. The National Capital Region continues to report the most cases, with half of national cases, where Metro Manila mayors have recommended the extension of the general community quarantine status for the month of October.

In Malaysia, the weekly number of new cases has been increasing for the past 3 weeks, with 1319 cases reported in the past week (40 new cases per 1 million population). The state of Sabah has been the worst affected in recent weeks, accounting for 77% of cases reported in September. A number of

clusters in other states have also been linked to travellers from Sabah. Malaysia has a nationwide recovery movement control order (RMCO) in place and most communities and services are operating under these limited restrictions. However, targeted enhanced movement control orders (TEMCO), the most stringent form of community and business restrictions, have been implemented in a number of areas with high levels of community transmission.

The Solomon Islands recorded their first COVID-19 case: a student returning from the Philippines on a repatriation flight. The Solomon Islands have planned to use repatriation flights to return students studying in the Philippines and Indonesia. Since early January 2020, WHO has been working closely alongside Pacific Governments and Ministries of Health, in collaboration with partners, to ensure that countries are well prepared to respond to the threat of COVID-19.

Key weekly updates

- **Diagnostics:** WHO issued the [first](#) and [second](#) Emergency Use Listing for a quality antigen based rapid diagnostic test. [WHO published guidance](#) highlights the value of these tests in areas where community transmission is widespread and where nucleic acid amplification-based diagnostic testing is either unavailable or where test results are significantly delayed. On 28 September, the Access to COVID-19 Tools (ACT) Accelerator announced 120 million high-quality, affordable [COVID-19 antigen rapid tests to be made available to low- and middle-income countries](#).
- **Diagnostics:** WHO published the final version of [Target Product Profiles \(TPP\)](#) for priority diagnostics. These TPPs describe the desirable and minimal acceptable profiles for four tests: (i) point of care tests for suspected cases and their close contacts where reference assay testing is unavailable, or turnaround times obviate clinical utility; (ii) tests for diagnosis or confirmation of acute or subacute infection, suitable for low or high-volume needs; (iii) point of care test for prior infection; and (iv) tests for prior infection for moderate to high volume needs.
- **COVAX:** The Director-General Dr Tedros, in his regular [media briefing](#) on 2 October, highlighted 168 have joined COVAX. Through the ACT Accelerator and COVAX Facility, any vaccines that are proven to be safe and effective will be rolled out equitably across the world.
- **International Day of Older Persons:** On 1 October, the International Day of Older Persons, WHO launched a [package of tools](#), including a digital application to help health and social workers provide better care for older people. A [data portal](#) was also launched that will compile data on global indicators for monitoring the health and well-being of people aged 60 and over. Globally, older persons and those receiving long term care, accounts for a majority of COVID-19 severe cases and deaths.
- **Mental Health:** Billions of people around the world have been affected by the COVID-19 pandemic, which is having an added impact on people's mental health. On 10 October, World Mental Health Day, WHO is organizing a [Big Event for Mental Health](#). The advocacy event will focus on the urgent need to address the world's chronic under-investment in mental health – a problem that has been thrown into the spotlight during the COVID-19 pandemic.
- **Preparedness:** During the United Nations General Assembly, a high-level event on '[Sustainable preparedness for health security and resilience: Adopting a whole-of-society approach and breaking the "panic-then-forget" cycle](#)' was organized and co-hosted by Finland, France and Indonesia, along with the WHO. As the world crossed a grim milestone with over a million lives lost to COVID-19, with many more expected to have died from unprecedented disruptions to health systems. The event highlighted the need for sustainable health emergency preparedness as COVID-19 will not be the world's last health emergency.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines

on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Coronavirus disease (COVID-19)

Data as received by WHO from national authorities, as of 27 September 2020, 10 am CEST

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

To date, over 32.7 million COVID-19 cases and 991 000 deaths have been reported to WHO. During the week of 21–27 September, there were more than 2 million new cases and 36 000 new deaths reported, which is similar to the numbers reported the previous week. Cumulative deaths are expected to exceed one million in the coming week.

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, 30 December 2019 through 27 September 2020**

**See [data table](#) and [figure notes](#).

The Region of the Americas continues to carry the highest incidence of COVID-19 globally (Table 1), reporting similar numbers of new cases and deaths as the previous week. The Region accounts for 38% of all new cases and 52% of all new deaths reported in the past seven days. The Eastern Mediterranean Region showed the greatest increase (9%) in cases in the past week, while the European Region reported a substantial rise in deaths, with a 9% increase compared to the previous week. The WHO African,

Western Pacific and South-East Asia Regions reported decreases in the new case and deaths over the past week.

Additional region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

**See data, table and figure notes.

Situation by WHO Region

African Region

The African Region continues its decreasing trend for the seventh week, reporting a 7% decrease in new cases and a 14% decrease in new deaths. During the past week, 33 of the 49 affected countries reported either a decrease in deaths or no deaths. South Africa continues to report the highest number of new cases and new deaths followed by Ethiopia, Uganda, Algeria and Mozambique. South Africa also has the highest number of cumulative cases and deaths per one million population in the Region, followed by Cabo Verde which has reported increasing numbers of cases and deaths over the past month.

Cases in Mozambique have consistently increased over the last four weeks stretching health system capacity. More than half of the new cases (and total cases) are in the capital city, Maputo. Mozambique's overall case rate, however, remains relatively low: 248 cases per million population and two deaths per million population.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 27 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Region of the Americas remains the most affected WHO Region, accounting for 50% of all reported cases and 55% of deaths. The Region reported similar numbers of new cases and deaths this past week as compared to the previous week and accounts for 38% of new cases and 52% of new deaths.

The United States of America, Brazil, Argentina and Colombia continue to report the highest number of new cases in the past week. Mexico reported the sixth highest number of new cases and third highest number of new deaths.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 27 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

Over the past month, the number of new cases and deaths reported in the Eastern Mediterranean Region has consistently increased, with a 9% and 3% increase respectively. The highest numbers of new cases were reported by Iraq, Iran and Morocco. Somalia, Jordan, United Arab Emirates and Tunisia reported the greatest relative increase in cases compared to the previous week. While Iraq reported the highest number of new deaths, Bahrain and Jordan reported the greatest increase in deaths compared to the previous week.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 27 September 2020**

**See data, table and figure notes

European Region

While the number of new cases and deaths reported in the European Region continued to increase in the past seven days, the rate slowed (Figure 6), with only a 5% increase in new cases and 9% increase in new deaths reported (compared to 11% and 27% increase, respectively, the previous week). France, the Russian Federation, Spain and the United Kingdom continue to report the highest numbers of new cases. Turkey reported the third highest deaths in last seven days after the Russian Federation and Spain.

In France, the highest 7-day incidence was observed in the regions of Ile-de-France, Hauts-de-France and Provence-Alpes-Côte d'Azur – the latter including the city of Marseille, which has emerged as the epicenter of the country's second wave in recent weeks. While the number of hospitalized cases has doubled in the past 10 days, hospitalization numbers remain a magnitude smaller than observed earlier this year and hospital stays have tended to be shorter. Nonetheless, test positivity rates have continued to trend upwards (reaching 7.4% on 27 September), and 58/101 departments are now classified in the red zone indicating very high levels of infection.

In the United Kingdom, there has been an increase in the number of people testing positive for COVID-19 in all age groups, with the regions of Greater Glasgow and Clyde, the North West and the North East reporting the highest incidence in the past week. Wales has reported the highest rates of infection to date (727.7 per 100 000 population), followed by England (664), Northern Ireland (566.6) and Scotland (504.7).

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 27 September 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

The South-East Asia Region is the second most affected Region, accounting for 21% and 11% of cumulative cases and deaths, respectively. While the Region had been reporting increasing cases and deaths since March, in the past week, a 7% decrease in new cases and a 3% decrease in new deaths were observed. The countries reporting the highest number of new cases continue to be India, Indonesia and Bangladesh, while Myanmar reported the highest increase in cases (92% increase) and deaths (80% increase) compared to the previous week.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 27 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

Overall, the Western Pacific Region continues to show the lowest cumulative cases, accounting for just 2% of global cases and 1% of all deaths. The Philippines and Japan account for the highest number of new cases and new deaths in the Region. All countries in the Region except Malaysia, Papua New Guinea, and Guam reported decreases in new cases, as compared to the previous week. Only Malaysia reported an increase in new deaths.

Incidence of COVID-19 in Papua New Guinea remains low. An 8-fold increase was reported in August (396 cases) compared to July (52 cases). The number of cases reported so far in September (73 cases) is lower but there may be other undetected cases since the testing and overall health care capacity in the country are limited.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 27 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- COVID-19: Nearly 33 million cases and one million deaths in 9 months. As Dr Mike Ryan, Executive Director of WHO's Health Emergencies Programme said at the press conference on Friday [25 September](#), "the realities of getting a vaccine out there in the next nine months is a big task for everyone involved. There is a lot that can be done to save lives, both in terms of disease control, existing life-saving measures and the innovations that are coming down the pipe. Are we willing to make the investments now that are needed in the ACT Accelerator, especially in COVA "
- A total of 67 higher income economies have joined the [COVA Facility](#), with another 34 expected to sign, joining 92 low- and middle-income economies eligible for support for the procurement of vaccines. However, so far [only a tenth of the 35 billion needed for scale-up and impact have been received, a small investment considering that the global economy is expected to contract by trillions of US dollars this year alone](#). WHO's aim is to have two billion doses of vaccine available by the end of 2021.
- A new report from Every Woman Every Child, "[Protect the Progress: Rise, Refocus, Recover, 2020](#)" warns that the COVID-19 crisis is exacerbating existing inequities, with reported disruptions in essential health interventions disproportionately impacting the most vulnerable women and children. [There is no doubt that the pandemic has set back global efforts to improve the health and well-being of women and children, but that should only serve to strengthen our resolve](#), said Dr Tedros Adhanom Ghebreyesus, WHO Director-General.
- [WHO has released a video series, Science in 5, in which experts explain the science about specific issues related to COVID-19](#). So far five episodes have been released on subjects including herd immunity, SARS-CoV2, myths vs science, and reopening schools. Watch these short videos on WHO's [YouTube](#), [Instagram](#), [Facebook](#), [Twitter](#), and [LinkedIn](#) accounts or listen to the podcasts.
- On 23 September, WHO together with the UN, specialised agencies and partners called on countries to develop and implement action plans to promote [the timely dissemination of science-based information and prevent the spread of false information](#) while respecting freedom of expression.
- WHO has published the [Emergency Global Supply Chain System \(COVID-19\) catalogue](#), which lists all medical devices, including personal protective equipment, medical equipment, medical consumables, single use devices, laboratory and test-related devices that may be requested through the [COVID-19 Supply Portal](#).

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines

on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Erratum, 29 September 2020: Incorrect epidemic curve x-axis labels appeared in the Weekly Epidemiological Update published 28 September. These have been corrected here.

Coronavirus disease (COVID-19)

Data as received by WHO from national authorities, as of 10 am CEST 20 September 2020

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [Rolling updates on COVID-19](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

To date, over 30.6 million COVID-19 cases and 950 000 deaths have been reported to WHO.

From 14 through 20 September, there were almost 2 million new cases of COVID-19, which represents a 6% increase compared to the previous week, and the highest number of reported cases in a single week since the beginning of the epidemic. During the same period, there was a 10% decrease in the number of deaths, with 36 764 deaths reported in the past seven days (Figure 1).

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, 30 December 2019 through 20 September 2020**

**See data table and figure notes.

With the exception of the African Region, an increase in the weekly case incidence was reported across all WHO regions in the last seven days (Table 1, Figure 2). Overall, the Region of the Americas continues to carry the highest burden of COVID-19 globally, accounting for over 38% of all new cases reported in the past seven days, although the region has reported a 22% decrease in new deaths. The WHO European Region showed the greatest rise in deaths in the past week, with a 27% increase compared to the previous week.

The WHO South-East Asia Region has continued to report an increase in new COVID-19 deaths, with over 9000 deaths in the past week, accounting for 25% of all reported deaths and surpassing 100 000 total COVID-19 deaths since the beginning of the pandemic. In addition, the region accounts for 35% of new cases reported in the past week. The Eastern Mediterranean and Western Pacific regions have both reported a slight increase in reported cases and deaths over the last three weeks. The African Region continues to show a marked decline with decreases of 12% and 16% in reported cases and deaths respectively in the past week.

Additional region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

Situation by WHO Region

African Region

For the last six weeks, the African Region has continued to report a decrease in both COVID-19 cases and deaths. During the past week, 33 of the 49 affected countries reported either a decrease in deaths or no deaths. The region has reported almost 25 000 cumulative deaths to date, of which South Africa accounts for 15 900 (64%). South Africa continues to report the highest number of new cases and new deaths, followed by Ethiopia, Algeria and Mozambique.

Notably, 35 of 49 affected countries/territories/areas in the Region continue to report ongoing community transmission.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 20 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Region of the Americas remains the most affected WHO Region, accounting for 50% of all reported cases and 55% of deaths. Even though the Region has reported an increase of 10% in the number of new cases in the past week, it also accounts for the largest decrease in deaths compared to the previous seven days (-22%) (Figure 4). Thirty-two out of the 48 affected countries and territories in the Region report community transmission, while only eight report sporadic transmission.

The countries reporting the highest numbers of new cases in the past week include the United States of America, Brazil, Argentina and Colombia. The number of daily cases reported in Ecuador has remained relatively high, with an average of more than 500 cases reported daily in September.

The marked decrease in the number of deaths in the Region has been driven mainly by a decrease in Colombia, Mexico, Ecuador and Bolivia in the past seven days, while the United States of America and Brazil continue to report the highest number of deaths, each reporting over 5000 new deaths in the past week.

While Argentina was one of the countries in the Americas with the lowest incidence of cases and deaths during the first few months of the pandemic, over the last few months the weekly incidence of cases has been rising rapidly, and test positivity rates have exceeded 40% in recent weeks.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 20 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

The number of cases and deaths reported in the Eastern Mediterranean Region have consistently increased over the last three weeks (Figure 5), and have increased by 8% and 14% respectively in the last seven days. The highest numbers of new cases were reported by Iraq, Iran and Morocco. Jordan, Oman and Tunisia reported the greatest relative increase in cases compared to the previous week. While Iran reported the highest number of new deaths, Tunisia and Afghanistan reported the greatest increase in deaths compared to the previous week.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 20 September 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

The number of cases and deaths reported in the European Region increased by 11% and 27% respectively in the past seven days (Figure 6), with France, the Russian Federation, Spain and the United Kingdom reporting the highest numbers of new cases in the past week. Iceland and Cyprus have reported the greatest percentage increase in new cases in the past week.

The Region has been experiencing a slight increase in the number of reported deaths over the past four weeks, reaching over 4000 new deaths in the past seven days. Hungary and Denmark reported the highest relative increase in deaths in the past week, while the United Kingdom continues to report the highest number of cumulative deaths, with almost 42 000.

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 20 September 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

The South-East Asia Region is the second most affected Region and currently accounts for 35% and 25% of cases and deaths, respectively, newly reported globally in the past seven days. Although the number of cases and deaths has been increasing steadily since March, the increases have slowed, with increases in new cases and deaths of only 1% and 4% respectively in the past week. The countries reporting the highest number of new cases continue to be India, Indonesia and Bangladesh, while Myanmar and Nepal showed the highest increase in new cases in the past seven days.

The countries reporting the highest number of new deaths per million population include India and Maldives, with 6 and 4 deaths per million population respectively, while Myanmar continues to show the highest increase in deaths in the past week.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 20 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

Overall, the Western Pacific Region continues to show the lowest cumulative cases, accounting for less than 2% of global cases and less than 1.5% of all deaths. The Philippines and Japan accounted for the greatest number of new cases and new deaths in the Region. Relative increases in the number of deaths were reported in Malaysia, New Zealand and Papua New Guinea.

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 20 September 2020**

Key weekly updates

- As the world comes together at an unprecedented mostly virtual [75th UN General Assembly](#) from 15-31 September, [WHO has three messages to share](#):
 1. **Equitable access to COVID-19 tools.** WHO calls on world leaders to support the [Access to COVID-19 Tools \(ACT\)-Accelerator](#), a unique international collaboration to fast-track the development, production and equitable access to COVID-19 tests, treatments, and vaccines globally, while strengthening health systems.
 2. **Maintain the momentum towards achieving [the Sustainable Development Goals](#).** The pandemic risks unravelling decades of gains made in health and development. [According to a recent WHO survey](#), 90% of countries are experiencing disruptions to essential health services.
 3. **We must prepare for the next pandemic together, now.** A year ago the independent Global Preparedness Monitoring Board warned of the threat of a pandemic, calling for global leaders to take urgent, united action to prepare. Last week, the Board issued its 2020 report, '[A World in Disorder](#)', which outlined five urgent actions to be taken: responsible leadership; engaged citizenship; strong and agile systems for health security; sustained investment; and robust global governance of preparedness.
- WHO Director-General Dr Tedros, in his regular [media briefing](#) on Friday, highlighted that this is a critical moment for countries. As cases and deaths have started to spike again, he called upon leaders to put targeted measures in place which can help suppress the spread of the virus and ensure that health systems and workers are protected. Individuals must also practise physical distancing, clean their hands frequently, wear a mask as advised, cough and sneeze safely away from others, avoid crowds, and keep windows and doors open when they can't meet friends and family outside.
- WHO has published new guidance on [school-related public health measures](#) that examines considerations for school operations, and the measures needed to minimize the risk to students and staff of COVID-19.
- On 17 September, we celebrated [World Patient Safety Day](#) to raise global awareness of the importance of health worker safety and its interlinkages with patient safety. The COVID-19 pandemic has exerted unprecedented pressure on health systems worldwide. Health systems can only function with health workers, and a knowledgeable, skilled and motivated health workforce is critical for the provision of safe care to patients.
- WHO has released a slide set on '[What we know about the long-term effects of COVID-19](#)'. Typically people recover from COVID-19 after two to six weeks; however, for some people, including young adults and persons with no underlying medical conditions who were not hospitalized, symptoms may linger or recur for weeks or months following initial recovery. Some patients develop medical complications that may have lasting health effects. Much is still unknown, and more time and research are needed to understand the long-term effects of COVID-19.

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practices, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines

on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Coronavirus disease (COVID-19)

Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 10 am CEST 13 September 2020

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [Rolling updates on COVID-19](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

In the week from 7 through 13 September, there were over 1.8 million new cases of COVID-19, comparable to the previous seven days (Table 1); while deaths increased slightly as compared to the previous week, with over 40 600 deaths reported.

The Region of the Americas has consistently registered the greatest number of reported cases for many weeks. It continues to account for nearly half of the global total of cases even as cases have declined in the reporting week. The African Region also showed a decline in reported cases this week and was the only region to report a decline in deaths.

Figure 1: Number of COVID-19 cases reported weekly by WHO Region, and global deaths, 30 December 2019 through 13 September 2020**

**See [data table](#) and [figure notes](#).

The European region reported the third-highest number of new cases, amounting to 16% of the global total, and is the region with the second-highest cumulative number of cases per million population (5 172 cases per million population).

In recent weeks schools have been re-opening in a number of countries throughout the six WHO regions. WHO has published both a [Question and Answer](#) and guidance on [considerations for school-related public health measures in the context of COVID-19](#).

Additional region-specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), and [Western-Pacific Region](#).

Figure 2. COVID-19 cases per million population reported in the last seven days by countries, territories and areas, 7 through 13 September 2020**

**See data, table and figure notes.

Situation by WHO Region

African Region

The African Region has witnessed declining trends in the number of new cases reported (a 14% decrease in cases and a 15% decrease in deaths in the past seven days), with 26 of the 47 affected countries reporting decreases in the past week. While this is encouraging, vigilance is still essential as many factors may be influencing these trends such as testing capacity and strategy, along with delays in reporting in some areas.

While South Africa continues to account for the greatest number of cumulative reported cases in the region (Table 2), disease incidence by 1 million population is highest in Mayotte (12 367 per million). Cumulative deaths per million population remains the highest in South Africa (260 per million population).

Elsewhere in the region, WHO has [donated life-saving equipment and medical supplies](#) and helped established a new [WHO-supported COVID-19 testing molecular laboratory](#) in Makeni City, northern Sierra Leone, to facilitate scaling up of testing capacity for the disease in the country. Sierra Leone has continued to report COVID-19 cases throughout the pandemic amidst other ongoing communicable diseases outbreaks. Sierra Leone reported 53 cases and 1 death this week, resulting in a cumulative total of 263 cases per million population and 9 deaths per million population.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, as of 13 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

As cases in the Region of the Americas continues to rise and social dynamics change, the WHO Regional Office has compiled [infographics covering a range of issues related to COVID-19](#), including tips on how to stay safe and healthy during the pandemic for different ages, risk groups and settings.

While the numbers are relatively low (Table 2) as compared to other countries in the region, Guadeloupe has reported its highest number of cases this week, rising from 428 new cases in the previous weekly update to 1717 new cases this week, and the transmission pattern has now moved from clusters of cases to community transmission. Cumulative cases and deaths have increased relative to the territory's population, over 100% in cases (3 406 to 7 698 per million population) and a 20% increase in cumulative deaths (50 to 60 per million population) in the past seven days.

In the past week, Curaçao has shown the highest weekly increase in the number of cases since the start of the outbreak in the country, a 250% increase in weekly new cases reported which translates to a 73% increase in cumulative cases from 475 to 823 per million population.

While cases reported this week in Costa Rica are in line with the average for the country in the past few weeks, the number of deaths reported has increased by 84% and a 24% in the incidence of deaths relative to the country's population (92 to 114 per million population) in the past week.

Figure 4: Number of COVID-19 cases and deaths reported weekly by the WHO Region of the Americas, as of 13 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

Cases in the Region continue to rise, an increase of 14% in the past seven days, and currently account for 6% of global cases. Seasonal religious and cultural mass gatherings, wedding celebrations and other social events have contributed to the upsurge of cases in different countries in the region. Upticks of cases reported in Tunisia and Jordan have been linked to ceremonies and celebrations.

Cases in Morocco have reached a peak at approximately 2 000 per day, an increase of 41% in weekly new cases, resulting in 2 288 cases per million population. The majority of new cases (42%) are being reported in the Casablanca-Settat region, where public health and safety measures are being scaled up in response. In Jordan, the number of weekly new cases has increased by 54%, increasing the cumulative cases per million population from 231 to 300. Deaths have remained stable at 2 per million population. Additionally, the first two cases of COVID-19 were confirmed in a refugee camp hosting Syrian refugees. In Libya, the number of new confirmed cases of COVID-19 has more than doubled over the past two weeks; both the cumulative cases and deaths per million population in Libya has increased by 30% in the past seven days. Given the acute shortages of tests and laboratory capacity, the real number of cases is likely to be much higher. WHO is supporting the efforts of Libyan authorities to increase the number of COVID-19 tests and trace all contacts.

Figure 5: Number of COVID-19 cases and deaths reported weekly by the WHO Eastern Mediterranean Region, as of 13 September 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

The European Region accounts for 16% of global COVID-19 cases and 25% of the deaths. While France reported the highest number of new cases in the past seven days, the top three countries in the region reporting the highest cumulative cases per million population are San Marino (21 834 cases per million population), Andorra (17 395 per million population) and Israel (16 430 per million population). The countries reporting the highest cumulative number of deaths relative to their population are San Marino (1 238 per million population), Belgium (856 per million population) and Andorra (686 per million population).

Figure 6: Number of COVID-19 cases and deaths reported weekly by the WHO European Region, as of 13 September 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

In the South-East Asia Region, India, Indonesia and Bangladesh continue to report the highest number of cases, although the Maldives accounts for the highest number of cumulative cases relative to its population (16 746 per million population). The region recorded 22% of all new deaths in the last seven days but retains low overall cumulative deaths relative to the region's population (46 per million population)

Myanmar is continuing to show increasing case numbers, with a greater than 250% increase in weekly new cases, resulting in more than a doubling of cumulative incidence from 24 to 51 per million population. Deaths remain low, with an incidence of <1 per million population. An influx of local travelers from Rakhine State to Yangon Region occurring since the end of August has contributed to increasing trends; as incidence rises, there are concerns of spread of cases from Myanmar across its border with Thailand, where cases have remained low (50 per million population) since peaks in early April.

Figure 7: Number of COVID-19 cases and deaths reported weekly by the WHO South-East Asia Region, as of 13 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

Overall, the Western Pacific Region has the lowest cumulative cases (278) and deaths (6) per million population. The Philippines, Japan and the Republic of Korea have the greatest number of new cases in the region; however, Singapore holds the largest number of cumulative cases per million population at 9 804. Malaysia showed an increase in weekly new cases of nearly 650%, averaging about 68 cases per day. Prior to this, Malaysia had been reporting fewer than 20 cases per day since the end of July. In the last seven days the cumulative cases per million population rose by 5% to 305 cases per million population).

Figure 8: Number of COVID-19 cases and deaths reported weekly by the WHO Western Pacific Region, data as of 13 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- The first meeting of the [International Health Regulations \(IHR 2005\) Review Committee](#) on the functioning of the IHR during the COVID-19 pandemic was held this week. WHO Director-General Dr Tedros stated that the committee would review the functioning of the IHR during the COVID-19 response, including IHR provisions related to, but not limited to, the following six areas:
 - The convening of the Emergency Committee and its working modalities, and in particular, the binary mechanism for declaring a Public Health Emergency of International Concern;
 - The international coordination and collaboration for response, including the role and functioning of national IHR focal points;
 - Outbreak alert, verification and risk assessment, information sharing and communication;
 - Additional health measures in relation to international travel;
 - Implementation and reporting of IHR core capacities, including the possibility of establishing peer review processes for capacity assessments;
 - Examining progress made on the implementation of recommendations from previous IHR review committees.
- As public health and safety measures begin to reduce COVID-19 cases to manageable levels in some countries, the epidemiological practice of contact tracing must go into full force. This becomes complicated and time-consuming very quickly, especially in the context of COVID-19, as the virus can be transmitted between people without even causing symptoms. While conventional contact tracing methods will always remain relevant, [digital tools present an opportunity to optimize traditional approaches](#). WHO is pursuing multiple avenues at once: behind the scenes bringing together private sector, innovators and governments to scale up technology and digital inclusion; and on the ground, for example in humanitarian settings.
- In his [second regular media briefing](#) of last week, WHO Director-General Dr Tedros highlighted that COVID-19 is like no other disease in history, in that it has seen such rapid development in research. In April, together with the European Commission and several other partners, WHO launched the Access to COVID-19 Tools (ACT) Accelerator, to catalyze the development of and equitable access to vaccines, diagnostics and therapeutics. [WHO co-hosted the first ACT Accelerator Facilitation Council meeting last week](#). The Council reiterated that there is a need for a significant increase in funding in order for the ACT Accelerator to be able to deliver on its goals.
- The ability to confirm COVID-19 disease relies on the accurate detection of the SARS-CoV-2 virus. WHO has published interim guidance for countries who are considering the [integration of rapid immunoassays into COVID-19 outbreak management programs](#) and has also revised guidance on [diagnostic testing for SARS-CoV-2](#) which provides more background information on clinical diagnostic algorithms and new findings from the literature and best practices.
- Surveys by UNICEF and WHO reveal that the [COVID-19 pandemic has resulted in major disruptions to health services, which threaten to undo decades of hard-won progress](#), particularly in the number of global deaths in children under five years old, which was at its lowest point on record in 2019.

Table 2. Number of COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, as of 13 September 2020**

Reporting Country/Territory/Area	New cases in last 7 days	Cumulative cases	Cumulative cases per million population	New deaths in last 7 days	Cumulative deaths:	Cumulative deaths per million population	Transmission classification

Data, table and figure notes

Data presented are based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practice, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/ areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Coronavirus disease (COVID-19)

Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 10 am CEST 6 September 2020

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [Rolling updates on COVID-19](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Cumulatively, nearly 27 million COVID-19 cases and 900 000 deaths have been reported to WHO to date. Over 1.8 million new cases and 37 000 new deaths were reported for the week ending 6 September, a 5% increase in the number of cases and a 2% decrease in the number of deaths compared to the previous week (24 to 30 August) (Figure 1).

Figure 1: Number of COVID-19 cases reported weekly by WHO region, and total deaths, 30 December to 6 September 2020**

**See [data table](#) and [figure notes](#).

The WHO South-East Asia Region continued to show the highest increase in new COVID-19 cases in the past week, compared to the previous week, with over 600 000 new cases reported. A weekly increase in the number of new reported cases was seen in the European and Eastern Mediterranean Regions, while the African and Western Pacific Regions declined in both cases and deaths compared with last week. The Region of the Americas has seen a 1% increase in reported cases, but a 4% decrease in deaths, and continues to carry the highest burden of the disease globally, accounting for nearly half of all new cases reported in the past seven days.

Region specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), [Western-Pacific Region](#).

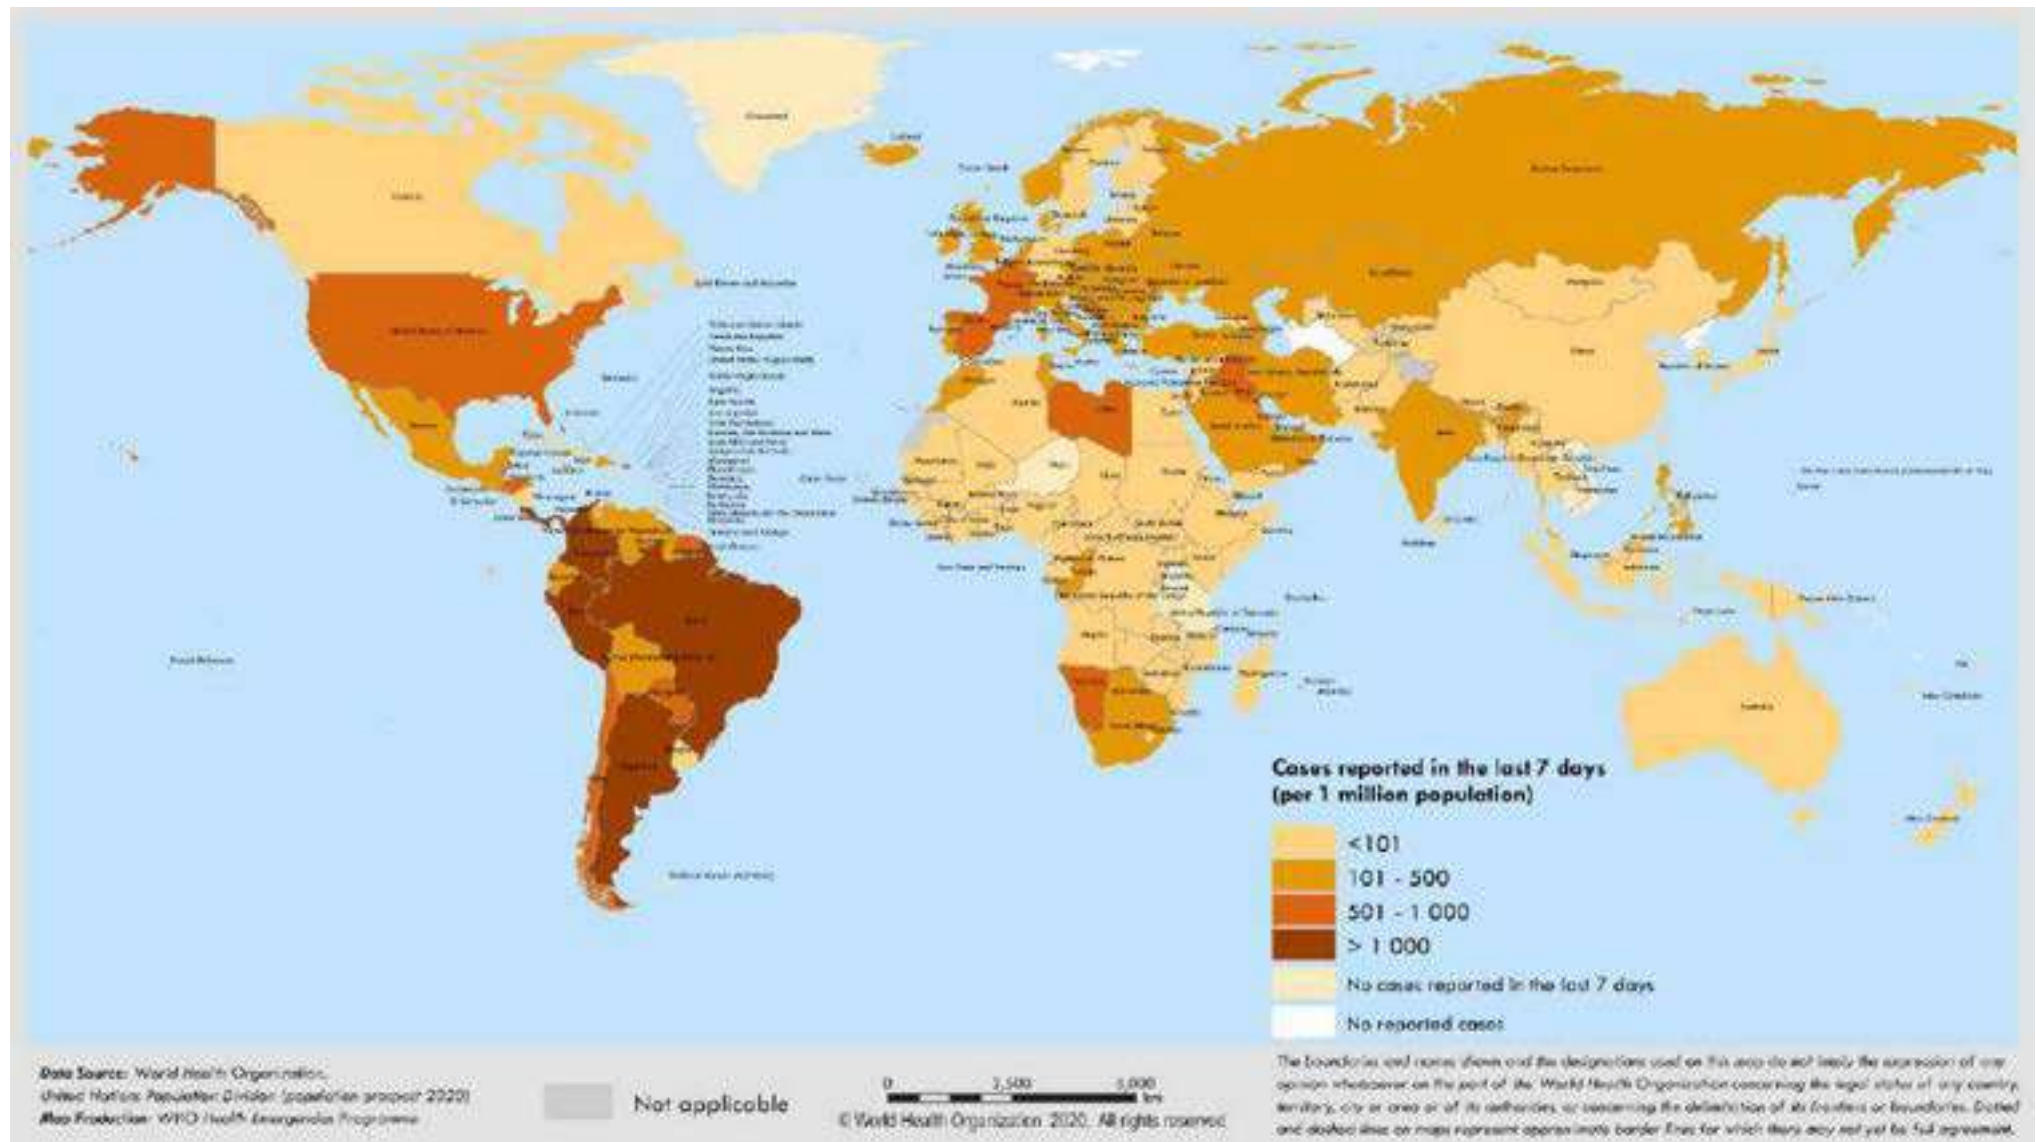

Table 1. Newly reported and cumulative COVID-19 confirmed cases and deaths, by WHO Region, data as of 6 September 2020**

WHO Region	New cases in last 7 days (%)	Change in new cases in last 7 days	Cumulative cases (%)	New deaths in last 7 days (%)	Change in new deaths in last 7 days*	Cumulative deaths (%)
Americas	862 478 (46%)	1%	14 001 390 (52%)	22 325 (59%)	-4%	484 079 (55%)
South-East Asia	616 795 (33%)	14%	4 689 943 (18%)	8 124 (22%)	4%	83 400 (10%)
Europe	247 125 (13%)	4%	4 475 267 (17%)	3 015 (8%)	9%	222 279 (25%)
Eastern Mediterranean	92 699 (5%)	6%	1 996 246 (8%)	2 244 (6%)	-1%	52 710 (6%)
Africa	38 639 (2%)	-12%	1 083 152 (4%)	1 207 (3%)	-14%	22 929 (3%)

Situation by WHO Region

African Region

While cases in South Africa have declined this week, the country continues to report the highest number of cases in the region, accounting for 37% of all new cases. Other countries reporting a high number of cases include Ethiopia, Algeria, Namibia and Kenya.

While cases in Nigeria have declined by 35% this week, compared to the previous week, the number of reported deaths increased by 200%.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, data as of 6 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The United States of America and Brazil account for nearly three quarters of all COVID-19 cases in the Americas. Argentina, Colombia, and Peru account for the next largest proportion in new cases in the region.

In the Bahamas, , public health and social measures have been extended from mid-August as the island continues to experience an increase in cases (18%) and deaths (15%).

Figure 4: Number of COVID-19 cases and deaths reported weekly by Region of the Americas, data as of 6 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

The highest numbers of new cases in the region have been seen in Iraq, Iran, Morocco, Saudi Arabia and Kuwait, and Iraq continues to report the highest number of new COVID-19 cases.

In Afghanistan, cases have increased by 77% this week compared to last week, although new deaths are down by 33% as compared to last week. In Bahrain, cases have increased by nearly 44% in the past seven days as have cases in Tunisia where trends show an increase in cases since the country reopened its borders at the end of June.

Figure 5: Number of COVID-19 cases and deaths reported weekly by Eastern Mediterranean Region, data as of 6 September 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

In the European Region, France reported the highest number of new cases in the past seven days with nearly 44 000 cases followed closely by Spain at just over 40 000. Russia and Ukraine also continue to report a high number of cases. In Ukraine, cases are continuing to rise, with a 19% increase in the past seven days. The government has extended the public health and social measures until the end of October.

While cases in Italy have continued to show an increase, this week's 9% increase was substantially lower than last week's nearly 85% increase.

Figure 6: Number of COVID-19 cases and deaths reported weekly by European Region, data as of 6 September 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

India continues to report a very high number of new cases, reaching nearly 600 000 new cases in the past seven days, with an average of approximately 81 582 cases per day, the highest numbers of daily new cases in the past week. In Myanmar, cases have shown a marked increase of nearly 87% in the past seven days.

Figure 7: Number of COVID-19 cases and deaths reported weekly by South-East Asia Region, data as of 6 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

The three countries reporting the highest number of new cases in the Western Pacific Region are the Philippines, Japan and Republic of Korea. However, the Philippines have seen a decrease in new cases in the past week compared to the previous week. French Polynesia has seen an increase of just over 29% in cases in the past seven days; while stricter containment rules were imposed last month, both the government and the French High Commission ruled out more stringent public health and social measures, with schools set to reopen on 7 September.

Figure 8: Number of COVID-19 cases and deaths reported weekly by Western Pacific Region, data as of 6 September 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- WHO Director-General Dr Tedros, in his [regular media briefing](#) on Friday, spelled out four essential things that all countries, communities and individuals must focus on to rein in COVID-19:
 - Prevent amplifying events. COVID-19 spreads very efficiently among clusters of people;
 - Reduce deaths by protecting vulnerable groups, including older people, those with underlying conditions and essential workers;
 - Empower people: individuals must play their part by taking the measures we know work to protect themselves and others – stay at least one metre away from others, clean hands regularly, practise respiratory etiquette, and wear a mask as recommended; and
 - Governments must take tailored actions to find, isolate, test and care for cases, and trace and quarantine contacts.
- WHO has published [guidance on the use of corticosteroids in the treatment of patients with COVID-19](#). Based on current evidence, two recommendations are made: a strong recommendation for systemic corticosteroid therapy for 7 to 10 days in patients with severe and critical COVID-19, and a conditional recommendation not to use corticosteroid therapy in patients with nonsevere COVID-19.
- WHO has also published [guidance for individuals who tend to the bodies of persons who have died of suspected or confirmed COVID-19](#). The document updates guidance issued on 24 March with the following new or modified content: clarification of body bag requirements; clarification of personal protective equipment (PPE) requirements during autopsies; updated ventilation requirements during autopsy.
- At the [first meeting of the Technical Advisory Group on Behavioural Insights and Sciences for Health](#), Dr Tedros said "The COVID-19 pandemic has taught the world that public health agencies and experts need a better understanding of how people and societies behave and make decisions in relation to their health". The group brings together some 21 advisors representing a variety of countries and expertise in related disciplines.
- Many parents, educators and children themselves have concerns and anxieties about going to school during these times. WHO/Europe and the Ministry of Health, Italy, have released a [joint statement on schooling during the COVID-19 pandemic](#), discussing some of the measures that can be considered for risk reduction in school settings. These include: protective measures, such as masks, hand hygiene, and social distancing; specific policies for at-risk children; and online learning.
- While the race to find safe and effective COVID-19 vaccines continues, African countries are signing up to a ground-breaking initiative, which aims to secure at least 220 million doses of vaccine for the continent, once licensed and approved. [All 54 countries on the continent have expressed interest in COVAX, a global initiative](#) which is co-led by the Coalition for Epidemic Preparedness Innovations (CEPI), Gavi, the Vaccine Alliance (Gavi) and the World Health Organization (WHO). The European Commission has joined the COVAX Facility, and Dr Tedros thanked the Commission for its contribution of 400 million euros.
- WHO has launched an appeal for at least US\$76 million to support Lebanon in the wake of the blasts four weeks ago, which left more than 6,500 people injured, 300,000 people homeless, and severely damaged critical health infrastructure and medical supplies. Any individual or organization can contribute through the [WHO Foundation](#).

Table 2. Number of COVID-19 confirmed cases and deaths reported in the last seven days by countries, territories and areas, African Region, data as of 6 September 2020**

Data, table and figure notes

Data presented is based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practice, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/ areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Coronavirus disease (COVID-19)

Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 10 am CEST 30 August 2020

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [Rolling updates on COVID-19](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Over 1.8 million new COVID-19 cases and 38 000 new deaths were reported to WHO in the week ending 30 August, a 1% increase in the number of cases and 3% decrease in the number of deaths compared to the previous week (17 to 23 August) (Figure 1). A cumulative total of nearly 25 million cases and 800 000 deaths have been reported since the start of the outbreak.

Figure 1: Number of COVID-19 cases and deaths reported weekly by WHO region, 30 December to 30 August 2020**

**See [data table](#) and [figure notes](#).

Overall, the Region of the Americas continues to carry the highest burden of COVID-19 globally, accounting for nearly half of all new cases reported in the past seven days, although within the region there have been slight decreases in new cases and deaths in the past week. The WHO South East Asia Region showed the highest rise in new cases in the past week, with over 500,000 new cases reported. In the European Region, new cases and new deaths have continued to increase over the past seven days compared to the previous week. Along with the Region of the Americas, the percentage change in new cases in Africa, the Eastern Mediterranean, and Western Pacific Regions have all declined compared with last week.

Region specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), [Western-Pacific Region](#).

**See data, table and figure notes.

Situation by WHO Region

African Region

Several countries in the Region that were previous COVID-19 hotspots have recorded a reduction in case incidence including Ghana, Kenya, Gabon and Madagascar. While the observed declining trends are encouraging, the figures should be interpreted cautiously as they may be affected by many factors, including the current testing capacity and strategy, and delays in reporting.

Cases in Ethiopia have continued to rise, reaching new highs this week (10 621 cases) with Addis Ababa remaining the worst affected region. In response, the Ethiopian government, with support from WHO, have launched the COVID-19 Enhanced Community Based Activities and Testing Campaign (ComBAT). ComBAT aims to reach out to over 60 million individuals in a variety of settings, conduct 200 000 tests and treat 10 000 cases.

At 622 551 cases, South Africa has the fifth highest number of COVID-19 infections globally and the highest number in Africa. However, there has been a marked decline in new cases since they peaked on 25 July at 13 944 cases, and the downward trend has continued this week with new cases falling by 34% (Figure 3). As a result, the government has eased public health and social measures while reminding the public to remain vigilant.

Figure 3: Number of COVID-19 cases and deaths reported weekly by the WHO African Region, data as of 30 August 2020**

**See [data](#), [table](#) and [figure notes](#)

Region of the Americas

The Americas account for approximately 13% of the world's population, but over 50% of officially reported global cases and deaths. Currently, while the biggest drivers of the case counts in the region have observed a moderate decline or stabilisation of case incidence ([Figure 4](#)), increasing trends are now being seen in other parts of the region including Peru, Mexico, Colombia, and Argentina. Social gatherings could also have contributed to the increase in cases in the region. WHO recommends [avoiding the 'three c's'-crowded places, close contact settings, and confined and enclosed settings](#). More advice from WHO on how to protect yourself and others from the spread COVID-19 can be found [here](#).

The United States of America has the highest number of cases in the world – over 5.8 million cases, a quarter of the global total. However, the country has witnessed a decline in new cases from previous peaks in July of over 70 000 cases per day to an average of 41 000 new cases per day this past week. As school and university campuses have reopened, there have been news reports of students testing positive. WHO has published [guidance for school-related public health measures in the context of COVID-19](#).

Although cases in Colombia have declined in the past week, they have been gradually increasing since June and continued caution is required. After five months of implementing public health and social measures, Colombia will begin easing the measures beginning 1 September.

Argentina has reported new peaks in the number of cases reported weekly and an upward trajectory in cases and deaths since June. Cases in Mexico declined by 6% in the past week and have declined gradually across the month of August. Mexico is implementing remote teaching and education for children to reduce transmission.

Figure 4: Number of COVID-19 cases and deaths reported weekly by Region of the Americas, data as of 30 August 2020**

**See [data](#), [table](#) and [figure notes](#)

Eastern Mediterranean Region

The Eastern Mediterranean Region has observed a fluctuating incidence of new cases in recent weeks (Figure 5). The highest number of new cases have been seen in Iraq, Iran, Morocco, Saudi Arabia, and Kuwait. WHO, in partnership with the Iraqi Ministry of Health and its implementing partners, has concluded another round of a [COVID-19 awareness-raising campaign](#) that intensified community outreach efforts to educate people on measures to limit transmission of COVID-19. The campaign reached more than 5 million people in four densely populated and heavily affected areas in Basra, Wasit, Thi Qar and Missan. Campaign teams are moving to the Kurdistan region and will be targeting 9 heavily populated, high-risk areas in Sulaymaniyah province. Over the past week WHO has also [delivered 6 ambulances to the Ministry of Health of the Kurdistan region and 22 tonnes of COVID-19 equipment](#).

In Pakistan, cases have fallen from over 5 000 per day in mid-June to 2 871 cases in the past week. As the public health and social measures are lifted, the public is encouraged to take precautions to ensure a resurgence does not occur particularly as they celebrate the first 10 days of the month of Muharram, which started on 21 August.

Figure 5: Number of COVID-19 cases and deaths reported weekly by Eastern Mediterranean Region, data as of 30 August 2020**

**See [data](#), [table](#) and [figure notes](#)

European Region

Gradual increases continue to be observed in the European Region ([Figure 6](#)), with Spain, Russia, France, and Ukraine reporting the highest number of new cases this week. Spain has seen a resurgence since mid-July and cases are now reaching the peaks previously seen in March and April. July and August is the holiday season in Spain, and social interactions have likely contributed to the increased number of reported cases. Spain has deployed the military to support contact tracing activities.

France has also seen a growing number of cases since the end of July with cases rising from around 500 cases per day to approximately 4 773 cases per day over the past week.

Cases in Italy have shown a marked increase in the past seven days, up by 85% overall compared to last week.

In the European Region many of those who died of COVID-19 have been elderly people (as of this week 88% of all deaths were in persons aged 65 years and over). WHO has published comprehensive [guidance on preventing and managing COVID-19 across long-term care services](#).

Figure 6: Number of COVID-19 cases and deaths reported weekly by European Region, data as of 30 August 2020**

**See [data](#), [table](#) and [figure notes](#)

South-East Asia Region

South-East Asia has reported the largest week-on-week increase ([Figure 7](#)), largely due to increased case detections in India. India has reported nearly 500 000 new cases in the past seven days, a 9% increase compared to the previous seven days and the highest numbers of new cases globally. While these trends are concerning, the increase in cases should be seen against a substantive rise in testing in recent weeks.

In Indonesia, cases have been gradually increasing while there are also concerns about transmission among family members of school children as 40% of people aged 60 years and older in Indonesia live in three-generation households, meaning that they live with their children and grandchildren. WHO has published interim guidance on [considerations for school-related public health measures in the context of COVID-19](#) and a joint document with UNICEF and IFRC on [key messages and actions for COVID-19 prevention and control in schools](#). WHO has also convened a technical advisory group on schools.

Figure 7: Number of COVID-19 cases and deaths reported weekly by South-East Asia Region, data as of 30 August 2020**

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

The Philippines and Japan are reporting the highest number of new cases in the region this week although cases in Japan have been decreasing since the end of June with a 22% decrease in overall cases reported this week compared to last week. In the Philippines, a large percentage of cases have been reported from the National Capital Region.

Figure 8: Number of COVID-19 cases and deaths reported weekly by Western Pacific Region, data as of 30 August 2020**

**See [data](#), [table](#) and [figure notes](#)

Key weekly updates

- WHO has issued updated interim [guidance on hotels and other accommodation facilities](#) to help the sector protect the safety of staff and clients. See also the Q&A's on [Staying at hotels and accommodation establishments and COVID-19](#) and [Working in hotels and COVID-19](#).
- WHO has also released guidance for shipowners, seafarers, unions and associations and associated authorities for promoting [public health measures on cargo ships and fishing vessels](#). This complements guidance for employers to make sure they implement containment measures at [workplaces](#) and the related [Q&A](#).
- Speaking at his regular media briefing on 27 August, WHO Director-General Dr Tedros highlighted the momentous achievement of eradicating wild poliovirus in Africa and sleeping sickness in Togo. Dr Tedros went on to say that “[globally, we need the same spirit of solidarity and partnership that are helping to end polio and sleeping sickness to end the COVID-19 pandemic](#).”
- The results of a WHO [survey conducted to assess the impact of the COVID-19 pandemic on up to 25 essential health services in countries](#) show disruptions of essential health services in nearly all countries, and more so in lower-income than higher-income countries. The great majority of service disruptions were partial, which was defined as a change of 5–50% in service provision or use.
- WHO has [published an overview](#) of the structure, methodology, and assumptions used by the COVID-19 [Essential Supplies Forecasting Tool \(ESFT\)](#). The ESFT is designed to help governments, partners, and other stakeholders to estimate potential requirements for essential supplies to respond to the current pandemic of COVID-19. See also the ESFT [Frequently Asked Questions](#).

Data, table and figure notes

Data presented is based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practice, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/ areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

Coronavirus disease (COVID-19)

Weekly Epidemiological Update

Data as received by WHO from national authorities, as of 10am CEST 23 August 2020

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [Rolling updates on COVID-19](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

Over 1.7 million new COVID-19 cases and 39 000 new deaths were reported to WHO for the week ending 23 August, a 5% decrease in the number of cases and 12% decrease in the number of deaths compared to the previous week (10 to 16 August) ([Figure 1](#)). A cumulative total of over 23 million cases and 800 000 deaths have been reported so far.

Figure 1: Number of COVID-19 cases and deaths reported weekly by WHO region, 30 December to 23 August 2020**

**See [data table](#) and [figure notes](#).

With the exception of the South-East Asia and Eastern Mediterranean regions, a decrease in the weekly case incidence was reported across WHO regions in the last seven days ([Table 1](#), [Figure 2](#)). Although the WHO Region of the Americas remains the most affected, accounting for 50% of newly reported cases and 62% of deaths, the region had the largest decrease compared to the previous week. The South-East Asia Region, which is the second most active region, continues to report an increase accounting for 28% and 19% of newly reported cases and deaths respectively. In the European Region, the number of cases reported has consistently increased over the last three weeks, however, a slight decrease (1%) was reported in the most recent week, and the number of deaths have continued to decrease across the region. In the Eastern Mediterranean Region, the number of reported cases increased by 4% compared to the previous week, however, the number of reported deaths have consistently decreased over the last six weeks. Likewise, the African and Western Pacific regions reported overall decreases in case activity over the past week.

Region specific information can be found below: [African Region](#), [Region of the Americas](#), [Eastern Mediterranean Region](#), [European Region](#), [South-East Asia Region](#), [Western-Pacific Region](#).

Situation by WHO Region

African Region

The number of cases and deaths reported in the African Region decreased by 8% and 11% respectively in the past seven days, primarily due to a decrease in cases reported in Algeria, Ghana, Kenya, Senegal and South Africa ([Figure 3](#), [Table 2](#)).

Despite the overall decrease in the number of cases across the region, Uganda reported an increase of over 300%. Here, intensive community transmission has been reported in capital Kampala, particularly the divisions of Makindye, Nakawa and Kawempe.

Ethiopia has continued to report an increase in cases and deaths; and similarly, Namibia and Nigeria reported a 55% and 19% increase in the number of cases respectively. After 22 days of no cases, Mauritius reported two new cases in returnees who were repatriated from a neighbouring country.

****See [data, table and figure notes](#)**

Region of the Americas

The number of new cases and deaths decreased by 11% and 17% respectively compared to the previous week – primarily driven by reduced transmission rates reported from Brazil, Dominican Republic, Panama and the United States of America (Figure 4, Table 3).

Several countries and territories in the Caribbean islands have, however, reported a large increase in cases and deaths in the last seven days including Bahamas, Guadeloupe, Guyana, Jamaica and Trinidad and Tobago. The increase in cases observed in the Caribbean islands may in part be due to an increase in tourism.

The number of deaths reported in Peru decreased by 73% compared to the previous week, however, the incidence death rate in the last seven days (42 deaths per 1 million population) and the cumulative death rate in the country (826 deaths per 1 million population) remains the highest in the region.

Eastern Mediterranean Region

The number of cases reported in the Eastern Mediterranean Region increased by 4% in the last seven days, however, the number of deaths decreased by 5% and has consistently decreased over the last six weeks (Figure 5). Jordan, Lebanon and Tunisia reported the highest increase in cases compared to the previous week (Table 4).

Following the explosion in Beirut, Lebanon on 4 August, health care capacity in the area has diminished while COVID-19 cases continue to rise. As a result of the increase in cases, the Ministry of Public Health has established testing sites for residents and volunteers in the areas most affected by the blast. In addition, several health facilities are being restored and health supplies, including personal protective equipments, have been received.

European Region

Following a steady increase in the number of cases reported in the European Region over the last few weeks, the number of cases decreased slightly by 1% in the last seven days . The number of deaths reported in the last seven days decreased by 12%, continuing the downward trend ([Figure 6](#)). Not all countries are reporting a decline: Spain reported a 200% increase in the number of deaths in the last week compared to the previous week.

As countries across the region continue to report a resurgence in cases, several countries reported record high numbers in the last seven days including Croatia, , Czechia, Poland, Republic of Moldova and Ukraine ([Table 5](#)).

In response to the increase in cases across the region, many countries have recently re-introduced public health and social measures including travel restrictions.

South-East Asia Region

South-East Asia is the second most affected region and currently accounts for 28% and 19% of newly reported cases and deaths respectively, globally in the past seven days. The region has seen a steady increase in reported cases and deaths, with a 4% increase in the past seven days ([Figure 7](#)). India continues to report the majority of cases, and has reported a cumulative total of over three million cases, which accounts for 86% of all regional confirmed cases ([Table 6](#)).

The number of cases and deaths in Nepal has rapidly increased in the last seven days with a 49% and 52% increase respectively compared to the previous weeks. In addition, the testing capacity in Nepal has significantly increased resulting in a 38% increase in the testing rate.

**See [data](#), [table](#) and [figure notes](#)

Western Pacific Region

The number of cases reported in the Western Pacific Region decreased by 5% following a decrease in the number of new cases reported by Australia, China, Japan, Singapore and Viet Nam ([Figure 8](#), [Table 7](#)). The Republic of Korea reported a 180% increase in cases, mainly due to an increase in cases associated with religious gatherings.

Due to the increase in cases reported in the region, some Pacific Island countries are tightening border measures. There is also an increase in active testing and case finding systems across the region, which are facilitating the detection and control of clusters.

Key weekly updates

- During the 20 August Member State Briefing, WHO Director-General Dr Tedros highlighted that [“the fastest way to end the pandemic and reopen economies is to start by protecting the highest risk populations everywhere, rather than the entire populations of just some countries.”](#) He encouraged all countries to join the [COVAX Global Vaccines Facility](#), part of the [ACT Accelerator](#) – a critical mechanism for joint procurement and pooling risk across multiple vaccines. Nine vaccine candidates in the COVAX portfolio are currently going through Phase II or Phase III clinical trials. WHO is proposing to allocate vaccines in two phases. [Speaking on 24 August](#), Dr Tedros further explained that “the Facility is the critical mechanism for joint procurement and pooling risk across multiple vaccines so that whatever vaccine is proven to be safe and effective – all countries within the Facility will be able to access them. Most importantly, it is the mechanism to enable a globally coordinated rollout. This is in the interests of all countries, even those that have invested with individual manufacturers independently.” WHO issued terms of agreement for all countries to confirm how they prefer to join the mechanism, with a deadline of 31 August.
- WHO has published updated guidance on [quarantine measures for individuals](#) who are identified as contacts of a case of COVID-19. This includes information on the implementation of quarantine, as well as on ventilation and on the care of children in quarantine.
- WHO has published new guidance on the [use of masks for children](#) which serves as an annex to [previously published guidance on use of masks](#) in the context of COVID-19. The [Q&A on children and the use of masks](#) has recently been updated that provides answers to questions the public may have.
- Speaking at a [press conference held jointly with UNICEF](#), Dr Matshidiso Moeti, WHO Regional Director for Africa said “Schools have paved the way to success for many Africans. They also provide a safe haven for many children in challenging circumstances to develop and thrive. We must not be blind-sided by our efforts to contain COVID-19 and end up with a lost generation. Just as countries are opening businesses safely, we can reopen schools. This decision must be guided by a thorough risk analysis to ensure the safety of children, teachers and parents and with key measures like physical distancing put in place.” In a WHO survey of 39 countries in sub-Saharan Africa, only six schools were found to be fully open. The impact of extended disruption to education as a result of school closure is significant, and includes poor nutrition, stress, increased exposure to violence and exploitation, childhood pregnancies, and diminished educational progress. [WHO and UNICEF have urged governments in Africa to promote the safe reopening of schools](#) while taking measures to limit the spread of the virus.
- Globally, risks of COVID-19 resurgence remain in all countries that have managed to suppress transmission. Dr Hans Henri P. Kluge, WHO Regional Director for Europe, highlighted this during a statement to the press, indicating that as summer turns to autumn in the northern hemisphere, [we must make sure that we adopt the right public health measures to enable the safe return to school, manage the approaching influenza season, sustain our economies, and address the increased health risks to older people at this time of year.](#)

- The COVID-19 pandemic has negatively affected mental health and raised concerns of an increase in domestic violence in the Region of the Americas. WHO Regional-Director Carissa F. Etienne has counseled that [countries in the Americas should expand and invest in mental health services](#). WHO has produced several [publications on mental health and COVID-19](#), including advice for the public, a children's book, and other guidance.
- [Recent studies that show an increased risk among pregnant women of presenting with severe forms of COVID-19](#). In light of this, the WHO Regional Office for the Americas is encouraging countries to step up efforts to ensure access to prenatal care services for pregnant women.
- [WHO and the Jack Ma Foundation have donated COVID-19 essential medical supplies to 20 Caribbean countries](#). The supplies, which landed in Barbados, will be delivered through a new integrated regional logistics hub, supported by a donation by the Government of Canada.
- The COVID-19 pandemic has affected older people disproportionately, especially those living in long-term care facilities. Some countries indicate that more than 40% of COVID-19 related deaths have been linked to long-term care facilities. The WHO Regional Office for the Western Pacific has produced a [communication toolkit for long-term care facilities](#) to support Infection Prevention and Control. This complements a WHO policy brief released last month on [preventing and managing COVID-19 across long-term care services](#).

Data, table and figure notes

Data presented is based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon WHO [case definitions](#) and [surveillance guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practice, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/ areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.

- Erratum, Global Epidemiological Situation: The percentage change in the new cases and deaths in the last seven days have been corrected to align with the numbers provided in Table 1.
- Erratum, Situation by WHO Region, Eastern Mediterranean Region: The percentage change in the new cases reported last seven days have been corrected. The change aligns with numbers provided in Table 1.
- Erratum, Situation by WHO Region, South-East Asia Region: The percentage for new deaths reported in last seven days has been corrected. The change aligns with numbers provided in Table 1.

Coronavirus disease (COVID-19)

Weekly Epidemiological Update 1

Data as received by WHO from national authorities, as of 10am CEST 16 August 2020

For the latest data and information on COVID-19, please see:

- [WHO COVID-19 Dashboard](#)
- [Rolling updates on COVID-19](#)
- [WHO COVID-19 Weekly Operational Update](#)

Global epidemiological situation

For the week ending 16 August, over 1.8 million new COVID-19 cases and 39 000 new deaths were reported to WHO. This brings the cumulative total to 21.2 million confirmed COVID-19 cases including 761 000 deaths (Figure 1). In the past seven days, the number of reported daily cases rapidly increased with an average of 260 000 cases and 5 500 deaths.

Figure 1: Number of COVID-19 cases reported weekly by WHO region, 30 December to 16 August 2020**

**See [data table](#) and [figure notes](#).

The WHO Region of the Americas remains the most affected region in the past seven days, accounting for 53% of all newly confirmed cases and 75% of reported deaths. The South-East Asia Region continues to report an increase in cases and is currently the second most affected region. While the number of

cases decreased in the Eastern Mediterranean Region from the end of June through to 10 August, a 10% increase was reported in the number of cases reported in last seven days. The number of reported deaths, however, have continued to decrease across the region. The Western Pacific Region reported a large increase in the number of deaths compared to the previous seven days, although, this accounted for just 1% of the new deaths reported globally. The African Region reported a decrease in the number of cases and deaths over the past seven days (Table 1, Figure 2).

Due to the resurgence of cases in many countries, stay at home measures and travel restrictions are being re-implemented as part of efforts to limit the transmission of the virus.

Situation by WHO Region

Region of the Americas

In the WHO Region of the Americas, the number of cases reported last week remained stable compared to the previous week, with a less than 1% increase in the number of newly confirmed cases. However, during the same period, the number of deaths increased by 13%. The United States of America reported 360 000 new cases, a 4% decrease from the previous week. This decrease may in part be attributable to an underreporting of cases in California due to technology issues with the electronic laboratory reporting system which reports into the state's disease registry system.

The number of deaths reported in Peru increased by 220% in the past seven days to a total of 25 800 and a cumulative death rate of 784 deaths per 1 million population, which is currently the highest in the region.

Reports of COVID-19 cases among indigenous people are increasing across the region, with a reported mortality rate higher in this group compared to non-indigenous peoples.

South-East Asia Region

South-East Asia is the second most affected region and currently accounts for a respective 26% and 19% of newly reported cases and deaths globally in the past seven days. The region has seen a steady increase in reported cases and deaths, with a 9% increase in the past 7 days, compared to the previous week. India continues to report the majority of cases, accounting for 85% of all confirmed cases in the region as of 16 August and 92% of cases in the past seven days. The Maldives has recorded the highest incidence rate globally as cases continue to increase in the country.

European Region

The number of cases reported in the European Region has gradually increased in recent weeks, however, there was no substantial change in the number of cases reported this week compared to the previous week. Nevertheless, a number of countries in the region are showing a resurgence in cases including France, Germany, Netherlands, Spain and the United Kingdom. Several COVID-19 clusters, which have

contributed to the resurgence of cases, have been reported in meat processing and packaging facilities in a number of countries including Belgium, Denmark and Germany. A total of 2 480 deaths were reported across the region in the past seven days, which is a 21% decrease from the previous week. However, following a retrospective review process in the United Kingdom, over 5 000 deaths were deducted from the country's total COVID-19 deaths, resulting in a decrease of 2 728 deaths in the European region.

African Region

The African Region reported the largest decrease in the number of newly reported cases (27%) and deaths (21%) in the past seven days, primarily due to a decrease in cases reported in South Africa, Kenya, Algeria, Nigeria and Ghana.

Conversely, Ethiopia reported a 56% and 12% increase in the number of cases and deaths respectively, with more than half of the cases reported in Addis Ababa. Due to the increase in cases, a month-long testing and prevention campaign will be implemented with a plan to carry out 400 000 tests.

There are increasing reports of healthcare worker infections across the region, resulting in an overburdened health care system in several countries including Gambia, Kenya, Nigeria and Zimbabwe.

Eastern Mediterranean Region

Following five weeks of decline in the number of cases reported in the Eastern Mediterranean Region, a total of 88 700 new cases were reported in the last seven days, a 10% increase in the number of newly reported cases compared to the previous week. While countries in the Gulf state are reporting a decline in incidence, Iraq, Morocco, occupied Palestinian territory, Lebanon and Libya are reporting an increase in cases. The number of cases and deaths reported in Pakistan in the past seven days decreased by 20% and 24% respectively from the previous week, resulting in the lifting of lockdown restrictions across the country.

Western Pacific Region

The number of cases reported in the Western Pacific Region decreased by 5% as the number of new cases reported in Japan, Australia, Singapore and Viet Nam decreased in the past seven days. However, the number of deaths reported increased by 90% mainly due to increases reported in the Philippines, Japan, Viet Nam, China and Australia. The Republic of Korea continues to report cases associated with religious clusters and reported an increase of 210% in the number of cases compared to last week. On August 11, New Zealand reported a new locally acquired case, after recording 102 days with no community transmission. A total of 52 new cases have been reported in the past seven days resulting in a temporary lockdown of the northern part of the country. New Zealand is the third country in the region to report a resurgence in cases after a period of little or no known community transmission. Other countries include Australia and Viet Nam.

Key weekly updates

- “There are two essential elements to addressing the pandemic effectively: leaders must step up to take action and citizens need to embrace new measures...My message is crystal clear: suppress, suppress, suppress the virus.”

WHO Director-General Dr Tedros, at his regular media briefing on Monday, 10 August

- The [Access to COVID-19 Tools \(ACT\) Accelerator](#), is a global collaboration to accelerate the development, production, and equitable access to COVID-19 tests, treatments, and vaccines. Nine vaccine candidates are currently in the portfolio of the [vaccines pillar](#) (called COVAX) and going through phase two or phase three trials. This portfolio, already the broadest in the world, is constantly expanding. The ACT-Accelerator is the only up-and-running global initiative that brings together all the global research and development, manufacturing, regulatory, purchasing and procurement needed for all the tools required to end the pandemic.
- Access to basic handwashing facilities is a key condition for schools to be able to operate safely in the midst of the COVID-19 pandemic. Yet the latest data from the WHO/UNICEF Joint Monitoring Programme (JMP) found that [43% of schools worldwide lacked access to basic handwashing with soap and water in 2019](#). UNICEF and partners have published a [Framework for Reopening schools and guidance on hand hygiene](#), which compliments [Key Messages and Actions for COVID-19 Prevention and Control in Schools](#) and [Considerations for school-related public health measures in the context of COVID-19](#).
- WHO has published updated [guidance on home care for patients with suspected or confirmed COVID-19 and the management of their contacts](#). The document provides guidance on the issues to be considered when deciding whether or not to provide care for COVID-19 patients at home and offers advice for health workers and caregivers providing that care.
- WHO has published the [Emergency Global Supply Chain System \(COVID-19\) catalogue](#), which lists all medical devices, including personal protective equipment, medical equipment, medical consumables, single use devices, laboratory and test-related devices that may be requested through the [COVID-19 Supply Portal](#).

Table 1. Number of COVID-19 confirmed cases and deaths reported in the last seven days, by WHO Region, data as of 16 August 2020**

Data, table and figure notes

Data presented is based on official laboratory-confirmed COVID-19 case and deaths reported to WHO by country/territories/areas, largely based upon [WHO surveillance definitions and guidance](#). While steps are taken to ensure accuracy and reliability, all data are subject to continuous verification and change, and caution must be taken when interpreting these data as several factors influence the counts presented, with variable underestimation of true case and death incidence, and variable delays to reflecting these data at global level. Case detection, inclusion criteria, testing strategies, reporting practice, and data cut-off and lag times differ between countries/territories/areas. A small number of countries/territories/ areas report combined probable and laboratory-confirmed cases; efforts are underway to identify these for notation in the data table. Differences are to be expected between information products published by WHO, national public health authorities, and other sources.

The designations employed, and the presentation of these materials do not imply the expression of any opinion whatsoever on the part of WHO concerning the legal status of any country, territory or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted and dashed lines on maps represent approximate border lines for which there may not yet be full agreement. Countries, territories and areas are arranged under the administering WHO region.

The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by WHO in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters.

^[1] All references to Kosovo should be understood to be in the context of the United Nations Security Council resolution 1244 (1999). In the map, number of cases of Serbia and Kosovo (UNSCR 1244, 1999) have been aggregated for visualization purposes.

ⁱ Transmission classification is based on a process of country/territory/area self-reporting. Classifications are reviewed on a weekly basis and may be revised as new information becomes available. Differing degrees of transmission may be present within countries/territories/areas; classification is based on the highest category reported within a country/territory/area. Categories:

- No cases: with no confirmed cases;
- Sporadic cases: with one or more cases, imported or locally detected;
- Clusters of cases: experiencing cases, clustered in time, geographic location and/or by common exposures;
- Community transmission: experiencing larger outbreaks of local transmission defined through an assessment of factors including, but not limited to: large numbers of cases not linkable to transmission chains; large numbers of cases from sentinel laboratory surveillance; and/or multiple unrelated clusters in several areas of the country/territory/area;
- Pending: transmission classification has not been reported to WHO.

ⁱⁱ "Territories" include territories, areas, overseas dependencies and other jurisdictions of similar status.

[†] Other: includes cases reported from international conveyances.

Country, territory, or area-specific notes, updates and errata

Due to public health authorities conducting data reconciliation exercises which remove large numbers of cases or deaths from their total counts, negative numbers may be displayed in the new cases/deaths columns as appropriate. When additional details become available that allow the subtractions to be suitably apportioned to previous days, graphics will be updated accordingly. See the [log of major changes and errata](#) for details. Prior situation reports will not be edited; see covid19.who.int for the most up-to-date data.
